In 1872 a work appeared entitled *Supernatural Religion*, in which the evidences of religion generally, and those for the authenticity of the New Testament in particular, were somewhat roughly handled. This work created considerable sensation. It was written anonymously, and attributed to various celebrities of the day. In a series of masterly papers in the *Contemporary Review*, between December 1874 and May 1877, Dr Lightfoot undertook the defence of the New Testament canon; and the writer of the book, though never discourteously treated, was handled with some severity, and, in the opinion of most impartial judges, overthrown. About the same time Lightfoot was engaged in contributions to the *Dictionary of Christian Biography* and the *Dictionary of the Bible*, and he also joined the committee for revising the translation of the New Testament. In 1875 he became Lady Margaret Professor of Divinity in the place of Dr Selwyn. He had previously, in addition to the work mentioned above, written most able and learned commentaries on the Epistles to the Galatians, Philippians, and Colossians, the notes to which were distinguished by sound judgment and enriched from his large stores of theological learning. These commentaries may be described as to a certain extent a new departure in New Testament exegesis. Previously to Lightfoot's time commentaries, especially on the epistles, had not unfrequently consisted either of short homilies on particular portions of the text, or of endeavours to enforce foregone conclusions, or of attempts to decide with infinite industry and ingenuity between the interpretations of former commentators. Lightfoot, on the contrary, while not despising the labours of his predecessors, endeavoured to make his author interpret himself, and by considering the general drift of his argument to discover his meaning where it appeared doubtful. Thus he often recovered for the Church the meaning of a passage which had long been buried under a heap of contradictory glosses, and he founded a school in which English sobriety and common-sense were added to the industry and ingenuity of former commentators. Such services to the Church could not long remain unrewarded. Accordingly, in 1879 Lightfoot was elevated to the bishopric of Durham. His moderation, good sense, wisdom, temper, firmness, and erudition made him as successful in this position as he had been when professor of theology, and he speedily surrounded himself with a band of intelligent and scholarly young men, who aided him in the work of his diocese. The bishop endeavoured to combine his habits of theological study with the practical work of government of an important diocese. He continued to work at his editions of the *Apostolic Fathers*. In 1885 he published an edition of the Epistles of Ignatius and Polycarp, and he collected a large store of valuable materials for an edition of Clemens Romanus, which was published after his death. His defence of the authenticity of the Epistles of Ignatius is one of the most important contributions to that very difficult controversy. His unremitting labours impaired his health and shortened his splendid career at Durham. That diocese enjoyed only nine years of his wise, fatherly, and sympathetic rule, and of an influence for good felt as much by the pitmen as by their more cultivated and more educated fellow-citizens. At the age of 65 he was prematurely snatched away from the diocese he had ruled so well and wisely. He died at Bournemouth, 21st December 1889, and was succeeded in the episcopate by Westcott, his school-fellow and lifelong friend.

(J. J. L*.)

LIGHTHOUSES.

THIS article is supplementary to that in the earlier volumes of this Encyclopædia (ninth edition, vol. xiv.), and describes the principal developments which took place in lighthouse engineering—including fog-signalling, the construction of buoys and beacons, light-vessels, and subsidiary branches of coast lighting—during the last quarter of the 19th century. It will be convenient to divide the subject into sections as follows:—

1. Lighthouse structures.
2. Optical apparatus for lighthouses.
3. Lighthouse illuminants.
4. Unattended lights and beacons.
5. Light-vessels.
6. Illuminated buoys.
7. Fog signals.
8. Lighthouse administration.

1. Lighthouse Structures.

During the period under review comparatively few isolated and wave-swept lighthouses on rock foundations were constructed, but among these are one or two of paramount importance. The general design of such structures has differed but slightly from preceding examples of the class, but in important details considerable alterations and improvements have been effected. The following are among the chief examples of this branch of work:—

Eddystone Lighthouse.—The Corporation of Trinity House in 1877 determined on the erection of a new lighthouse in place of Smeaton's famous structure upon the Eddystone reef, near Plymouth. The site selected was 120 ft. south-south-east from Smeaton's lighthouse, where a suitable foundation was found, although a considerable section of the lower courses had to be laid below the level of low water. The vertical base is 44 ft. in diameter and 22 ft. in height. The tower is a concave elliptic frustum, and is solid, with the exception of a fresh-water tank, to a height

FIG. 1.—Plan of Entrance Floor, new Eddystone Lighthouse.

of 25 ft. 6 in. above high-water level. The walls above this level vary in thickness from 8 ft. 6 in. to 2 ft. 3 in. under the gallery. All the stones are dovetailed, both horizontally and vertically and on all inner faces, the stones of the foundation course being secured to the rock by Muntz-metal bolts. The tower contains 62,133 cub. ft. of Cornish and Irish granite, weighing 4668 tons. The height of the structure from low water ordinary spring tides to the mean focal plane is 149 ft., and it stands 133 ft. above high water. The

lantern is a cylindrical helically framed structure with domed roof. The astragals are of gun-metal and the pedestal of cast iron. The optical apparatus consists of two superposed tiers of refracting lens panels, 12 in each tier, of 920 mm. focal distance. The lenses subtend an angle of 92° vertically. The 12 lens panels are arranged in groups of two, thus producing a group flashing light showing two flashes of 2½ seconds' duration every half minute, the apparatus revolving once in 3 minutes. The burners are of the Douglass 6-wick mineral oil pattern, and are supplied with oil from pressure lamps. The intensity of the combined beam of light from the two apparatus is 79,000 candles. At the time of the completion of the lighthouse two bells, weighing 2 tons each, and struck by mechanical power, were installed for fog-signalling purposes, but since that date an explosive gun-cotton fog-signal has been erected, the bells being removed. The driving machinery which rotates the optical apparatus consists of a ½-h.p. caloric engine. At a lower level in the tower are installed two 21-inch parabolic silvered reflectors with 2-wick burners, throwing a fixed light of 12,000 candle-power over a danger known as the Hand Deep. The work of preparing the foundation was begun on the 17th July 1878, the foundation-stone being laid by the late duke of Edinburgh on the 19th August 1879. The last stone was laid on the 1st June 1881, and the light exhibited for the first time on the 18th May 1882. The upper portion of Smeaton's tower, which was removed on completion of the new lighthouse, was re-erected on Plymouth Hoe, where it replaced the old Trinity House sea mark. One of the principal features in the design of the new Eddystone lighthouse tower is the solid vertical base. This construction was much criticized at the time, but experience has proved that heavy seas striking the massive cylindrical structure are immediately broken up and rush round to the opposite side, spray alone ascending to the height of the lantern gallery. On the other hand, the waves striking the old tower at its foundation ran up the surface, which presented a curved face to the waves, and unimpeded by any projection until arriving at the lantern gallery, were partially broken up by the cornice and then spent themselves in heavy spray over the lantern. The shock to which the cornice of the gallery was exposed was so great that stones were sometimes lifted from their beds. The new Eddystone tower presents one point of dissimilarity from Smeaton's structure, in that the stones forming the floors consist of single corbel stones built into the wall and constituting solid portions thereof. In Smeaton's tower the floors consisted of stone arches, the thrust being taken by the walls of the tower itself, which were strengthened for the purpose by building in chains in the form of hoops. The system of constructing corbelled stone floors was first adopted by Stevenson in the Bell Rock lighthouse.

Bishop Rock Lighthouse.—The lighthouse on the Bishop Rock, which is the westernmost landfall rock of the Scilly Islands, occupies perhaps a more exposed situation than any other in the world. The first lighthouse erected there was begun in 1847 under the direction of the late Mr N. Douglass. The tower consisted of a cast and wrought iron open-work structure having the columns deeply sunk into the rock. On the 5th February 1850, when the tower was ready for the erection of the lantern and illuminating apparatus, a heavy storm swept away the whole of the structure. This tower was designed for an elevation of 94 ft. to the focal plane. In 1851 the erection of a granite tower was begun; the light was first exhibited in 1858. The tower had an elevation to the focal plane of 110 ft., the lower 14 courses being arranged in steps, or offsets, to break up the force of the waves. This structure also proved insufficient to withstand the very heavy seas to which it was exposed. Soon after its completion the 5-cwt. fog bell, fixed to the lantern gallery 100 ft. above high-water mark, was washed away, together with the flagstaff and ladder. The tower vibrated considerably during storms, and it was found that some of the external blocks of granite had been split by the excessive stress to which they had been exposed. In 1874 the tower was strengthened by bolting continuous iron ties to the internal surfaces of the walls. In 1881, when further signs of damage appeared, it was determined to remove the upper storey or service-room of the lighthouse, and to case the structure from its base upwards with granite blocks securely dovetailed to each other and to the existing work. At the same time it was considered advisable to increase the elevation of the light, and place the mean focal plane of the new apparatus at an elevation of 146 ft. above high-water mark. The work was begun in 1883, and the new apparatus was first illuminated on the 25th October 1887. During the operation of heightening the tower it was necessary to install a temporary light, consisting of a cylindrical lightship

lantern with catoptric apparatus; this was raised from time to time in advance of the structure as the work proceeded. The additional masonry built into the tower amounts approximately

Trinity House cylindrical helically framed pattern, 14 ft. in diameter, the glazing being 15 ft. in height. The optical apparatus consists of two superposed tiers of lenses of 1330 mm. focal distance, the lenses subtending a horizontal angle of 36° and a vertical angle of 80°. The apparatus consists of 5 groups of lenses, each group producing a double flashing light of one minute period, the whole apparatus revolving once in 5 minutes. The burners are of the 8-wick Douglass pattern. The maximum aggregate

FIG. 2.—Bishop Rock Lighthouse.

to 3220 tons. Profiting by the experience gained after the construction of the new Eddystone tower, Sir J. N. Douglass decided to build the lower portion of the improved Bishop Rock tower in the form of a cylinder, but with considerably increased elevation (Fig. 2). The cylindrical base is 40 ft. in diameter, and rises to 25 ft. above high-water mark. The lantern is of the usual

FIG. 3.—Biform Dioptric Apparatus, Bishop Rock Lighthouse.

Trinity House cylindrical helically framed pattern, 14 ft. in diameter, the glazing being 15 ft. in height. The optical apparatus consists of two superposed tiers of lenses of 1330 mm. focal distance, the lenses subtending a horizontal angle of 36° and a vertical angle of 80°. The apparatus consists of 5 groups of lenses, each group producing a double flashing light of one minute period, the whole apparatus revolving once in 5 minutes. The burners are of the 8-wick Douglass pattern. The maximum aggregate

power of the flash is 170,500 candles. A gun-cotton explosive fog-signal is attached to the lantern. The cost of the various lighthouses on the Bishop Rock has been as follows:—

1. Cast-iron lighthouse . . .	£12,500 0 0
2. Granite lighthouse . . .	34,559 18 9
3. Improved granite lighthouse . . .	64,889 0 0
Total . . .	<u>£111,948 18 9</u>

Ratray Head Lighthouse.—This lighthouse was constructed between the years 1892 and 1895 by the Northern Lighthouse Commissioners upon the Ron Rock, lying about one-fifth of a mile off Ratray Head, Aberdeenshire. The focal plane is 91 ft. above high water, the building being approximately 113 ft. in height. In the tower there is a fog-horn worked by compressed air. The optical apparatus, which rotates on a roller carriage, gives 3 flashes in quick succession every 30 seconds. The lenses are arranged in 4 panels, each containing 3 faces, and their focal distance is 920 mm. The optical elements for a vertical height of 68° are the ordinary plano-convex Fresnel profile. Refraction is carried to a vertical height of 80° by means of equiangular prisms. The intensity of the beam is 44,000 candles.

Beachy Head Lighthouse.—A new lighthouse is under construction upon the foreshore at the foot of Beachy Head, near Eastbourne, to replace the existing structure on the cliff, having an elevation of 284 ft. above high-water mark. Experience has proved that this particular light is frequently obscured by banks of mist or fog, while at a lower level the transparency of the

atmosphere is considerably less impaired. The Trinity House therefore decided in the year 1899 to proceed with the construction of a granite tower upon the foreshore at a distance of some 570 ft. from the base of the cliff. The foreshore at this point consists of chalk, and the selected site just bares at low water ordinary spring tides. The foundation course has been laid at a depth of 10 ft. below the surface, the area being excavated within a coffer-dam. The tower, which will be 47 ft. in diameter at the base, will have an elevation to the focal plane above high water of 103 ft., or a total height from foundation course to gallery coping of 123 ft. 6 in. The lower or solid portion of the tower has its face stones constructed in vertical offsets or steps in a similar manner to that adopted at the Wolf Rock and elsewhere. The tower is constructed with a facing of granite, all the stones being dovetailed in the usual manner. The hearting of the base is largely composed of concrete.

Fastnet Lighthouse.—A new granite lighthouse is in course of erection upon the Fastnet Rock off the south-west coast of Ireland. In the year 1895 it was reported to the Irish Lights Commissioners that the existing structure, which was completed in 1854 and consists of a circular cast-iron tower 86 ft. in height on the summit of the rock, was considerably undermined. It was subsequently determined to proceed with the erection of a granite structure of increased height and founded upon a sound ledge of rock on one side of the higher, but now considerably undermined, portion of the reef. This lighthouse tower, which was commenced in the year 1899, has its foundation laid near high-water level. The focal plane will be at a level of 160 ft. above high-water mark.

Wolf Trap Lighthouse.—This building was erected during the years 1893 and 1894 on Wolf Trap Spit in Chesapeake Bay, near the site of the old open-work structure which was swept away by ice early in 1893. The new tower is formed upon a cast-iron caisson 30 ft. in diameter sunk 18 ft. into the sandy bottom. The depth of water on the shoal is 16 ft. at low water. The caisson was filled with concrete, and is surmounted by a brick superstructure 52 ft. in height from low water to the focal plane of the light. A somewhat similar structure was erected in 1885-87 on the Fourteen Foot Bank in Delaware Bay, at a cost of £24,700. The foundation was, however, shifting sand, and the caisson was carried to a greater depth.

Minots Ledge Lighthouse.—This tower, although constructed before the period within the scope of this article, is of such interest as to warrant some mention. The tower, which is 89 ft. in height, is built of granite upon a reef off Boston Harbour, Mass., and occupied five years in construction, being completed in 1860, at a cost of £62,500. The rock just bares at low water. The stones are dovetailed vertically but not on their horizontal beds in the case of the lower 40 ft. or solid portion of the tower, bonding bolts being substituted for the horizontal dovetailed joints used in the case of the Wolf and other English towers. The shape of the tower is a conical frustum.

FIG. 4.—Alligator Reef Lighthouse.

to withstanding the effects of ice massing in solid fields thousands of acres in extent and travelling at considerable velocity. The tower is in shape the frustum of a cone, 32 ft. in diameter at the base and 93 ft. in height to the coping of the gallery. The focal plane is at a level of 97 ft. above the base. The lower 34 ft. of the tower is solid. The work was completed in 1874, having occupied four years. The cost amounted to approximately £78,000.

St George's Reef Lighthouse, California.—This structure consists of a square pyramidal stone tower rising from the easterly end of an oval masonry pier, built on a rock to a height of 60 ft. above the water. The focal plane is at an elevation of 146 ft. above high water. The site is an exceedingly dangerous one, and the work, which was completed in 1891, cost approximately £144,000.

Alligator Reef Lighthouse, Florida.—This tower is one of the finest iron sea-swept lighthouse structures in the world. It consists of a pyramidal iron framework 135½ ft. in height, standing on the Florida Reef in 5 ft. of water. Its cost was £37,000, and its construction is generally similar to the Fowey Rocks tower.

Rothersand Lighthouse.—This lighthouse, off the entrance to the river Weser (Germany), is a structure of great interest on account of the difficulties met with in its construction. The tower had to be founded on a bottom of shifting sand 20 ft. below low water and in a very exposed situation. Work was begun in May 1881, when attempts were made to sink an iron caisson under pneumatic pressure. Owing to the enormous scour removing the sand from one side of the caisson, it tilted to an alarming angle, but eventually it was sunk to a level of 70 ft. below low-water mark. In October of the same year the whole structure collapsed. Another attempt, made in May 1883, to sink a caisson of bi-convex shape in plan, 47 ft. long, 37 ft. wide, and 62 ft. in height, met with success, and after many difficulties the structure was sunk to a depth of 73 ft. below low water, the sides being raised by the addition of iron plating as the caisson sank. The sand was removed from the interior by suction. Around the caisson foundation were placed 74,000 cubic yards of mattress work and stones, the interior being filled with concrete. Towards the end of 1885 the lighthouse was completed, at a total cost, including the first attempt, of over £65,000. It is an iron structure in the shape of a concave elliptic frustum, its base being founded upon the caisson foundation at about half-tide level (Fig. 5). The light is electric, the current being supplied by cable from the shore. The focal plane is 78 ft. above high water or 109 feet from the sand level. The total height from the foundation of the caisson to the top of the vane is 185 ft.

FIG. 5.—Rothersand Lighthouse.

Land Structures for Lighthouses.—The erection of lighthouse towers and other buildings on land presents no difficulties of construction, and they are of ordinary architectural character. It will therefore be unnecessary to refer to them in detail. Attention should, however, be called to one of the most recent of Continental lighthouse towers, that known as the Phare d'Eckmuhl at Penmarc'h (Finistère), completed in 1897. The cost of this magnificent structure, 207 ft. in height from the ground, was largely defrayed by a bequest of £12,000 left by the marquis de Blocqueville. It is constructed entirely of granite, and is octagonal in plan. The total cost of the tower and other lighthouse buildings amounted to £16,000.

The tower at Ile Verge (Finistère), completed in 1902, has an elevation of 247 ft. from the ground level to the focal plane, and is probably the highest structure of its kind in the world.

TABLE I.—Comparative Cost of Exposed Rock Towers.

Name of Structure.	Total Cost.	Cub. ft.	Cost per cub. ft.
Eddystone, Smeaton (1759) .	£ 40,000 0 0	13,343	£ 2 19 11½
Bell Rock, Firth of Forth (1811)	55,619 12 1	28,580	1 19 0
Skerryvore, west coast of Scotland (1844) .	72,200 11 6	58,580	1 4 7¼
Bishop Rock, first granite tower (1858)	34,559 18 9	35,209	0 19 7½
Smalls, Bristol Channel (1861)	50,124 11 8	46,386	1 1 7¼
Hanois, Alderney (1862) .	25,296 0 0	24,542	1 0 7¼
Wolf Rock, Land's End (1869)	62,726 0 0	59,070	1 1 3
Dhu Heartach, west coast of Scotland (1872) .	72,584 9 7	42,050	1 14 6

Great Basses, Ceylon (1873) .	63,560 0 0	47,819	1 6 7
Minots Ledge, Boston, Mass., (1860)	62,500 0 0	36,322	1 17 2
Spectacle Reef, Lake Huron (1874)	78,125 0 0	42,742	1 16 2
Ar'men, France (1881) .	36,000 0 0	32,453	1 2 1

2. Optical Apparatus.

Feux-éclairs.—The most important development in the character of lighthouse illuminating apparatus that has occurred in recent years has been in the direction of reducing the length of flash. The initiative in this matter was taken by the French lighthouse authorities, and in France alone forty lights of this type were established between 1892 and 1901. The *feux-éclairs* which have been designed by the French engineers Bourdelles, Ribière, and others have usually a flash of $\frac{1}{10}$ to $\frac{1}{3}$ of a second duration, the intervals between the flashes being also small, 3 seconds to 7 seconds. In group-flashing lights of this character the intervals between the flashes are about 2 seconds, with periods of 7 to 10 or 15 seconds between the groups. The flashes are arranged in single, double, triple, or even quadruple groups, as in the older forms of apparatus. The use of short flash lights soon spread to other parts of the world, America, British colonies, China, Japan, and Germany and other European countries. In England the lighthouse at Pendeen (completed in 1901) exhibits a quadruple flash every 15 seconds, the flashes being about $\frac{1}{2}$ second duration (Fig. 6), while the bivalve apparatus erected on Lundy Island (1897) shows two flashes of $\frac{2}{3}$ second duration in quick succession every 20 seconds. The *feu-éclair* type of apparatus enables a far higher intensity of flash to be obtained than had hitherto been possible, without any corresponding increase in the luminous power of the burner or other source of light. This result depends entirely upon the greater ratio of condensation of light employed. Panels of greater angular breadth are used with a higher rotatory velocity.

Duration of Flash necessary for Physiological Perception.—The researches of numerous physiologists and physicists, among whom are Plateau, Helmholtz, Wundt, Bloch, and more especially Charpentier, confirm completely the experimental result obtained by M. Blondel at the *Dépôt des Phares* in Paris, that a flash of $\frac{1}{10}$ second is sufficient for the purpose of impressing a ray of light upon the retina of the eye. His researches proved that the exact time of full perception varies from .08 to .125 second. The French Lighthouse Service accordingly fixed the standard minimum duration of flash at $\frac{1}{10}$ second. This length of flash thus represents the standard of maximum efficiency of a light, and any increase in the duration naturally results, *ceteris paribus*, in a corresponding diminution in the intensity. It should be pointed out that sometimes it is advisable to increase the length of flash somewhat on account of local and practical considerations, but such increase need seldom be carried beyond $\frac{1}{4}$ or $\frac{1}{2}$ second. It has been urged that such short flashes are insufficient for taking bearings,

but the utility of a light in this respect does not seem to depend so much upon the actual length of the flash as upon its frequent recurrence at short intervals. At the Paris Exhibition of 1900 was exhibited a fifth-order flashing light giving short flashes at 1 second intervals; this represents the extreme to which the movement towards the reduction of the period of flashing lights has yet been carried. Mr Wigham has advocated a pulsating or "scintillating"

FIG. 6.—Pendeen Apparatus.

light emitting a series of flashes in such rapid succession that the luminous impression does not entirely leave the retina in the intervals.

Mercury Floats.—It has naturally been found impracticable to revolve the optical apparatus of a light with its mountings, sometimes weighing over 4 tons, at the high rate of speed required for *feux-éclairs* by means of the old system of roller carriages, though for some small revolving lights ball bearings have been successfully adopted. It has therefore become almost the universal practice to carry the rotating portions of the apparatus upon a mercury float. This beautiful application of mercury rotation was the invention of the late M. Bourdelles, and is now utilized not only for the high-speed apparatus, but also generally for the few examples of the older type still being constructed. The arrangement consists of an annular cast-iron bath or trough of such dimensions that a similar but slightly smaller annular float immersed in the bath and surrounded by mercury displaces

a volume of the liquid metal whose weight is equal to that of the apparatus supported. Thus a comparatively insignificant quantity of mercury, say 2 cwt., serves to ensure the flotation of a mass of over 3 or 4 tons. Certain differences exist between the type of float usually constructed in France and those generally designed by English engineers. In all cases provision is made for lowering the mercury bath or raising the float and apparatus for examination.

Group-Flashing Lights.—One of the most useful distinctions for lighthouses consists in the grouping of two or more flashes separated by short intervals of darkness, the group being succeeded by a longer eclipse. Thus two, three, or more flashes of say $\frac{1}{2}$ second duration each follow each other at intervals of 2 seconds and are succeeded by an eclipse of say 10 or 15 seconds, the sequence being completed in a period of say 20 or 30 seconds. In 1874 the late Dr John Hopkinson introduced the very valuable improvement of dividing the lenses of a dioptric revolving light and the panels of reflecting prisms above and below them, setting them at an angle to produce the 'group-flashing characteristic'. The first apparatus of this type constructed were those now in use at Tampico, Mexico, and the Little Basses lighthouse, Ceylon (double flashing). The latter was exhibited at the South Kensington Exhibition of 1876. The Casquets apparatus (triple flashing, 1877) was the first of the kind used in England. A group-flashing catoptric light had, however, been exhibited from the *Royal Sovereign* light-vessel in 1875. A group-flashing distinction was proposed for gas lights by Mr Wigham of Dublin, who obtained it in the case of a revolving apparatus by alternately raising and lowering the flame. The first apparatus in which this method was employed was at Galley Head, Co. Cork (1878). At this lighthouse four of Wigham's large gas burners with four tiers of first-order revolving lenses, eight in each tier, were adopted. By successive lowering and raising of the gas flame at the focus of each tier of lenses he produced the group-flashing distinction. This light shows, instead of one prolonged flash at intervals of one minute, as would be produced by the apparatus in the absence of a gas occulter, a group of short flashes varying in number between six and seven. The uncertainty, however, in the number of flashes contained in each group is found to be an objection to the arrangement. This device was adopted at other gas-illuminated stations in Ireland at subsequent dates. Dr Hopkinson's system has been very extensively used, all the group-flashing lights shown in the accompanying tables, except the gas lights and the light at Cape Byron, being designed upon the general lines he introduced. A modification of the system consists in grouping two or more lenses together separated by equal angles, and filling the remaining angle in azimuth by a reinforcing mirror or screen.

Eclipsing Group-Flashing Lights.—In 1898 Dr Purvis proposed the use of single or double-panel apparatus combined with an occulting screen or eclipser to obscure the burner at certain intervals. By rotating the apparatus at high speed, a series of flashes are thrown on the horizon, and may be interrupted for any desired time by automatically closing the occulter and thus obscuring the light. In a 2-panel optic, revolving once in 5 seconds, the flashes are at intervals of $2\frac{1}{2}$ seconds. If the occulter is closed during every alternate revolution, a group-flashing characteristic of two flashes in quick succession every 10 seconds is obtained, which effect could only be produced otherwise by the use of a 4-panel group-flashing apparatus, or some similar combination of the Hopkinson system considerably less efficient in luminous power than the 2-panel bivalve. A practical difficulty was found to exist with this arrangement in that the single occulting screen made it possible for an incorrect characteristic to be observed from certain positions in azimuth except within the limited angle of about 145° . To overcome this defect Dr Purvis and Mr A. Brebner independently invented an eclipsing screen constructed in two or more portions according as the apparatus is bivalve, trilateral, and so on. This device preserves the true characteristic of the light over the whole horizon, and was introduced in the first-order bivalve apparatus constructed in 1900-01 for New South Wales, and erected at Cape Byron lighthouse. In this apparatus, which consists of a 920-mm. focal distance bivalve, each lens having a horizontal angle of 152° , a double or divided eclipser is used which occults the light during every alternate revolution. The apparatus revolves once in 10 seconds, thus producing a characteristic of two flashes of $\frac{1}{2}$ second duration and 5 seconds apart every 20 seconds. The light has an intensity of 145,000 candles, being illuminated by a 6-wick mineral-oil burner.

Flashing Lights indicating Numbers.—Captain F. A. Mahan, late Engineer-Secretary to the United States Lighthouse Board, has devised for that service a system of flashing lights to indicate certain numbers. The apparatus installed at Minots Ledge lighthouse near Boston Harbour, Massachusetts, has a flash indicating the number 143, thus: - - - - - , the dashes indicating short flashes. Each group is separated by a longer period of darkness than that between successive members of a group. The flashes in

a group indicating a figure are about $1\frac{1}{2}$ seconds apart, the groups being 3 seconds apart. An interval of $16\frac{1}{2}$ seconds' darkness occurs between each repetition. The number is repeated every 30 seconds. Two examples of this system were exhibited by the United States Lighthouse Board at the Chicago Exhibition in 1893, viz., the second-order apparatus just mentioned and a similar light of the first order for Cape Charles on the Virginian coast. The lenses are arranged in a somewhat similar manner to an ordinary group-flashing light, the groups of lenses being placed on one side of the optic, while the other is provided with a catadioptric mirror. This system of numerical flashing for lighthouses has been frequently proposed in various forms, notably by Lord Kelvin. The installation of the lights described is, however, the first practical application of the system to large and important coast lights, and after eight years of actual service the lights have apparently given much assistance to navigators, who consider the system desirable. The great cost involved in the alteration of the lights of any country to comply with the requirements of a numerical system is an impediment to its general adoption.

Hyper-radial Apparatus.—In 1885 Messrs Barbier of Paris constructed the first hyper-radial apparatus (1330 mm. focal distance) to the designs of Messrs Stevenson. This had a height of 1812 mm. It was tested during the South Foreland experiments in comparison with other lenses, and found to give excellent results with burners of large focal diameter which would be unsuited for use with smaller apparatus. Apparatus of similar focal distance (1330 mm.) were subsequently established at Round Island, Bishop Rock, and Spurn Point in England, Fair Isle and Sule Skerry (Fig. 7) in Scotland, Bull Rock and Tory Island in Ireland, Cape d'Antifer in France, and at Pei Yü-shan in China.

At the Paris Exhibition of 1900 a fine example of a trilateral hyper-radial apparatus was shown, consisting of three lenses 11 ft. 6 in. in diameter, each subtending a horizontal angle of 120° , the whole being mounted upon a mercury float. The total weight of the revolving part of the light amounted to $8\frac{1}{2}$ tons, while the motive clock weight required to rotate this large mass at a speed of four complete revolutions a minute is only 11 cwt., and the weight of mercury required for flotation 594 lb. The complete apparatus weighed 13 tons. The introduction of incandescent and other burners of focal compactness and high intensity has rendered the use of optics of such large dimensions as the above, intended for burners of great focal diameter, unnecessary. It is now possible to obtain with a second-order optic (or one of 700 mm. focal distance), having a powerful incandescent petroleum burner in focus, a beam of equal intensity to that which would be obtained from the above-described apparatus having a 10-wick oil burner or 108-jet gas burner at its focus.

Stevenson's Spherical Lenses and Equiangular Prisms.—Mr C. A. Stevenson in 1888 designed a form of lens spherical in the horizontal and vertical sections. This admitted of the construction of lenses of long focal distance without the otherwise corresponding necessity of increased diameter of lantern. A lens of this type and of 1330 mm. focal distance was constructed in 1890 for Fair Isle lighthouse (1892). The spherical form loses in efficiency if carried beyond an angle subtending 20° at the focus, and to obviate this loss Mr Stevenson designed his equiangular prisms, which have an inclination outwards. It is claimed by the inventor that the use of equiangular prisms results in less loss of light and less divergence than is the case when either the spherical or Fresnel form is adopted. An example of this design is seen (Fig. 7) in the Sule Skerry apparatus (1895).

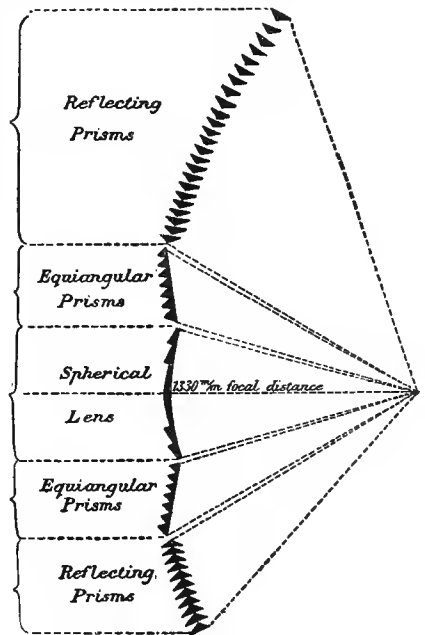

FIG. 7.—Sule Skerry Apparatus.

High-Angle Vertical Lenses.—Messrs Chance of Birmingham have manufactured lenses having 92° of vertical amplitude, but this result was only attained by using dense flint glass of high refractive index for the upper and lower elements. The St Catherine's lenses have even greater vertical angle prisms, 97° . Lenses of 92° angle were utilized for the apparatus established at Anvil Point (1881), the Eddystone (1882), and a few other stations. It is doubtful, however, whether the use of refracting elements for a greater angle than 80° vertically is attended by any material corresponding advantage.

Occulting Lights.—During the last twenty-five years of the 19th century the disadvantages of fixed lights became more and more appreciated, and at the present day the practice of installing such, except occasionally in the case of the smaller and less important of harbour or river lights, has practically ceased. The necessity for providing a distinctive characteristic for every light when possible has led to the conversion of many of the fixed-light apparatus of earlier years into occulting lights, and often to their supersession by more modern and powerful flashing apparatus. The occulting apparatus generally adopted consists of a cylindrical screen, fitting over the burner, rapidly lowered and raised by means of a cam wheel at stated intervals. The cam wheel is actuated by means of a weight or spring clock. Varying characteristics may be procured by means of such a contrivance—single, double, triple, or other systems of occultation. The eclipses or periods of darkness bear much the same relation to the times of illumination as do the flashes to the eclipses in a revolving or flashing light. In the case of a first-order fixed light the cost of conversion to an occulting characteristic does not exceed £250 to £300. With apparatus illuminated by gas the occultations may be produced by raising and lowering the gas at stated intervals.

Leading Lights.—In the case of lights intended to act as a lead through a narrow channel or as direction lights, it is undesirable to employ a flashing apparatus. Fixed-light optics are employed to meet such cases, and generally fitted with occulting mechanism. A typical apparatus of this description is that now in course of erection at Gage Roads, Fremantle, West Australia (Fig. 8). The occulting bright light covers the fairway, and is

FIG. 8.—Gage Roads Direction Light.

flanked by sectors of occulting red and green light marking dangers and intensified by vertical condensing prisms. A good example of a holophotal direction light was exhibited at the 1900 Paris Exhibition, and afterwards erected at Suzac lighthouse (France). The light consists of an annular lens 500 mm. focal distance, of 180° horizontal angle and 157° vertical, with a mirror of 180° at the back. The lens throws a beam of 3° amplitude in azimuth, and 300,000 candle-power, over a narrow channel. The illuminant is an incandescent petroleum-vapour burner with a mantle of 45 mm. diameter. Holophotal direction lenses of this type can only be applied where the sector to be marked is of comparatively small angle. The use of single direction lights frequently renders the construction of separate towers for leading lights unnecessary.

Coloured Lights.—Colour is used as seldom as possible as a distinction in lighthouses, entailing as it does a considerable reduction in the power of the light. It is necessary in some instances for differentiating sectors over dangers and for harbour lighting purposes. The use of coloured lights as alternating flashes

for lighthouse lights is not to be commended, on account of the unequal absorption of the coloured and bright rays by the atmosphere. When such distinction has been employed, as in the Wolf Rock apparatus, the red and white beams can be approximately equalized in initial intensity by constructing the lens and prism panels for the red light of larger angle than those for the white beams. With the introduction of group-flashing characteristics the necessity for such distinction disappeared. The Northern Lighthouse Commissioners have, however, perpetuated the alternating red and white characteristic in the new dioptric apparatus now being erected at Bell Rock lighthouse to replace the old catoptric light installed there in 1811. Owing to the absorption by the red colouring, the power of a red beam is only from 30 per cent. to 40 per cent. of the intensity of the corresponding white light. When red or green sectors are employed they should invariably be reinforced by mirrors, azimuthal condensing prisms, or other means to raise the coloured beam to approximately the same intensity as the white light.

3. *Illuminants.*

Electricity.—The first installation of electric light for lighthouse purposes in England took place in 1858 at the South Foreland, where the Trinity House established a temporary plant for experimental purposes. This installation was followed in 1862 by the adoption of the illuminant at the Dungeness lighthouse, where it remained in service until the year 1874, when the electric plant was removed and an oil-lit apparatus substituted. The earliest of the permanent installations now existing in England is that at Souter Point, which was illuminated in 1871. There are in England four important coast lights illuminated by electricity, and one, viz., Isle of May, in Scotland. Of the former St Catherine's in the Isle of Wight is the most powerful. Electricity was substituted as an illuminant for the then existing oil light on the 1st May 1888. The optical apparatus consists of a second-order 16-sided revolving lens giving flashes of 5 seconds' duration at intervals of 30 seconds. De Meritens alternators are installed. The Isle of May lighthouse, situated on an island at the mouth of the Firth of Forth, was first illuminated by electricity in 1887. The optical apparatus

FIG. 9.—Isle of May Apparatus.

consists of a second-order fixed-light lens with refracting prisms, and is surrounded by a revolving system of vertical condensing prisms which split up the vertically condensed beam of light into 8 separate beams of 3° in azimuth. The prisms are so arranged that the apparatus, making one complete revolution in the minute, produces a group characteristic of 4 flashes in quick succession every 30 seconds (Fig. 9). The fixed light is not of the ordinary Fresnel section, the refracting portion being confined to

an angle of 10° , and the remainder of the vertical section consisting of reflecting prisms. In France the old south lighthouse at La Hève was lit by electricity in 1863, with very satisfactory results. This installation

opening of the canal; Odessa in 1871; and at the Rother-sand, North Sea, in 1885. There are several harbour and other lights of minor importance in various parts of the world illuminated by electricity.

The table (II.) on the opposite page gives particulars of some of the more important electric lighthouses of the world.

Electric Lighthouse Installations in France.—

A list of the 13 lighthouses on the French coast equipped with electric light installations will be found in Table II. It has been already mentioned that the two lighthouses at La Hève were lit by electric light in 1863 and 1865. These installations were followed within a few years by the establishment of electricity as illuminant at Gris-nez. In 1882 M. Allard, the then Director-General of the French Lighthouse Service, prepared a scheme for the electric lighting of the French littoral by means of 46 lights distributed more or less uniformly along the coast line. All the apparatus were to be of the same general type, the optics consisting of a fixed belt of 300 mm. focal distance, around the outside of which revolved a system of 24 faces of vertical lenses. These vertical panels condensed the belt of fixed light into beams of 3° amplitude in azimuth, producing flashes of about $\frac{1}{2}$ second duration. To illuminate the near sea the vertical divergence of the lower prisms of the fixed belt was artificially increased. These optics are very similar to that in use at the Souter Point lighthouse, Sunderland. The intensities obtained were 120,000 candles in the case of fixed lights and 900,000 candles with flashing lights. As a result of a nautical inquiry held in 1886, at which date the lights of Dunkirk, Calais, Gris-nez, La Canche, Baleines, and Planier had been lighted, in addition to the old apparatus at La Hève, it was decided to limit the installation of electrical apparatus to important landfall lights—a decision which the Trinity House had already arrived at in the case of the English coast—and to establish new apparatus at six stations only. These were Créac'h d'Ouessant (Ushant), Belle-Ile, La Coubre at the mouth of the river Gironde, Barfleur, Ile d'Yeu, and Penmarc'h.¹ At the same time it was determined to increase the powers of the existing electric lights. The scheme as amended in 1886 is now almost complete, the last lights of the series being in course of erection (1902). In 1901 one of the lights decided upon in 1886 and installed in 1888—Créac'h d'Ouessant—was replaced by a still more powerful twin apparatus exhibited at the 1900 Paris Exhibition. Of the lights established under the Allard scheme, Gris-nez, La Canche, and Planier have been replaced by similar apparatus to that at Créac'h.

All the electrically lit apparatus, in common with nearly all other new optics established in France since 1893, have been provided with mercury rotation. The four most recent electric lights have been constructed in the form of twin apparatus, two complete and distinct optics being mounted side by side upon the same revolving table and with corresponding faces parallel. It has been found that a far larger aggregate candle-power could be obtained from two lamps with 16 mm. carbons and a current of 50 amperes than with one carbon of 23 mm. diameter in conjunction with a current of 100 amperes. A somewhat similar circumstance led to the choice of the twin forms for the two very powerful non-electric apparatus at Ile Verge (Figs. 10 and 11) and Ailly, particulars of which will be seen in Table III.

For the present it is intended to retain the De Meritens magnito-electric machines which were laid down some years ago at the French electric lighthouses. All these machines have

¹ The apparatus at Dunkirk has been replaced by the old Belle-Ile (1890) lens. At Barfleur and Belle-Ile are now being installed twin apparatus of the new Créac'h type.

FIG. 10.—Ile Verge Apparatus.

was followed in 1865 by a similar one at the north lighthouse, while in 1902 there were thirteen important coast lights in France illuminated by electricity. In other parts of the world, Macquarie lighthouse, Sydney, was lit by electricity in 1883; Tino, in the Gulf of Spezia, in 1885; and Navesink lighthouse, at the entrance to New York Bay, in 1898. Electric apparatus were also installed in the lighthouse at Port Said in 1869, on the

Note.—The methods of calculation adopted for determining the luminous intensities of lighthouse lights by the English and French authorities differ somewhat; the latter base their calculations upon data which give sometimes values 25 per cent. in excess of the figures arrived at by the English methods.

five induction coils, which, upon the installation of the twin optics, were separated into two distinct circuits, each consisting of 2½ coils. This modification has enabled the old plants to be used with success under the altered condition of lighting entailed by the use of two lamps. The generators adopted in the French Service for use at the later stations, where twin optics have been installed, differ materially from the old type of De Meritens machine. The Phare d'Eckmühl (Penmarc'h) installation serves as a type of the more modern machinery. The dynamos are alternating current two-phase machines, and are installed in duplicate. The two lamps are supplied with current from the same machine, the second dynamo being held in reserve. The speed is 810 to 820 revolutions per minute. Plant of a similar description will in all probability be laid down at a future date in all the electric lighthouses of this type.

The cost of a first-class electric lighthouse installation of the most recent type in France, including optical apparatus,

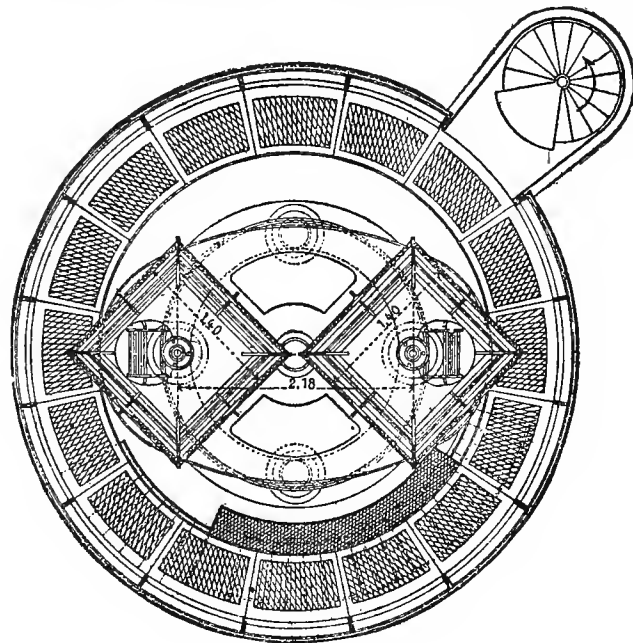

FIG. 11.—Plan of Ile Vierge Lantern.

lantern, dynamos, engines, air compressors, siren, &c., but not buildings, amounts approximately to £5886. The lamp generally adopted is a combination of the Serrin and Berjot principles, with certain modifications. Clockwork mechanism with a regulating electro-magnet moves the rods simultaneously and controls the movements of the carbons so that they are displaced at the same rate as they are consumed. It is usual to employ currents of varying power with carbons of corresponding dimensions according to the atmospheric conditions. In the French Service two variations are used in the case of twin apparatus produced by currents of 25 and 50 amperes at 45 volts with carbons 11 mm. and 16 mm. diameter (in some cases 30 and 60 ampere currents with 14 and 18 mm. carbons), while in single optic apparatus currents of 25, 50, and 100 amperes are utilized with carbons of 11 mm., 16 mm., and 23 mm. diameter. In England fluted carbons of larger diameter are employed with correspondingly increased current. Alternating currents have given the most successful results in all respects. Attempts to utilize continuous current for lighthouse arc lights have up to the present met with little success.

Efficiency of the Electric Light.—In 1883 the lighthouse authorities of Great Britain determined that an exhaustive series of experiments should be carried out at the South Foreland with a view to ascertaining the relative suitability of electricity, gas, and oil as lighthouse illuminants. The experiments extended over a period of more than twelve months, and were attended by representatives of most of the lighthouse authorities of the world. The results of the trials tended to show that the rays of oil and gas lights suffered to about equal extent by atmospheric absorption, but that oil had the advantage over gas by reason of its greater economy in cost of maintenance and in initial outlay on installation. The electric light was found to suffer to a much larger extent than either oil or gas light per unit of power by atmospheric absorption, but the infinitely greater total intensity of the beam obtainable by its use, both by reason of the high luminous intensity of the

electric arc and its focal compactness, more than outweighed the higher percentage of loss in fog. The final conclusion of the committee on the relative merits of electricity, gas, or oil as lighthouse illuminants is given in the following words:—"That for ordinary necessities of lighthouse illumination, mineral oil is the most suitable and economical illuminant, and that for salient headlands, important landfalls, and places where a very powerful light is required, electricity offers the greatest advantages."

Incandescent electric lighting has been adopted for the illumination of some light-vessels in the United States, a few small harbour and port lights, beacons, and in some cases buoys. The Cumbrae lighthouse in the Firth of Clyde is also lighted by incandescent electric lamps.

Coal gas had been introduced in 1837 at the inner pier light of Troon (Ayrshire), and in 1847 it was in use at the Heugh lighthouse (West Hartlepool). In 1878 canal coal gas was adopted for the Galley Head lighthouse, with 108-jet Wigham burners. Sir James Douglass introduced gas burners consisting of concentric rings perforated on the upper edges, and from two to ten in number. These gave excellent results and high intensity of candle-power, 2600 in the case of the 10-ring burner with a flame diameter at the focal plane of 5½ inches. These are in use at Bull Rock lighthouse, Haisboro' in Norfolk, and several other stations in England and Scotland. The use of multiple gas burners is not being further extended. Gas for lighthouse purposes generally requires to be specially made; the erection of gasworks at the station is thus necessitated and a considerable outlay entailed, which is avoided by the use of oil as an illuminant.

Incandescent Burners.—The invention of the Welsbach mantle places at the disposal of lighthouse authorities the means of producing a light of high intensity combined with great focal compactness. For lighthouse purposes other gaseous illuminants than coal gas are as a rule more convenient and economical, and give better results with incandescent mantles. Mantles have, however, been used with ordinary coal gas in many instances when a local supply is available.

Mineral Oil Burners.—Until the year 1846 the oil usually employed for lighthouse lamps was sperm. In that year colza or vegetable oil was introduced, and became the chief illuminant until the early 'seventies, when mineral oil was largely substituted in Great Britain for lighthouse purposes. In 1872 mineral oil was introduced at the Flamborough Head lighthouse, and since that date it has been utilized almost universally in cases where gas or electric light has not been installed. The large majority of lighthouses all over the world are now lit by mineral oil having a flash-point of over 140° F. The "Doty" burner was the first successful form of the multiple-wick type consuming mineral oil. Other improved oil burners have since been introduced, notably the patterns used in the English and French services, which are made in several sizes, varying from 1 to 8 concentric wicks, and in intensity from 20 to over 1800 candle-power. The improved 5-wick (1894) pattern used by the Trinity House gives a flame 3½ inches diameter at the focal plane, and of 800 candle-power. The lamps used for supplying oil to the burner are of two general types, viz., those in which the oil is maintained under pressure by mechanical action, and the constant level lamp.

Incandescent Mineral Oil Burners.—Incandescent lighting with high-flash mineral oil was first introduced by the French Lighthouse Service in 1898 at L'île Penfret lighthouse. The burners employed are all made on the same principle, but differ slightly in details according to the type of lighting apparatus for which they are intended. The principle consists in injecting the liquid petroleum in the form of spray mixed with air into a vaporizer heated by the mantle flame or by a subsidiary heating burner. A small reservoir of compressed air is used—charged by means of a hand-pump—for providing the necessary pressure for injection. On first ignition the vaporizer is heated by a spirit flame to the required temperature. A reservoir air pressure of 85 lb per square inch is employed, a reducing valve supplying air to the oil vessel at 28 lb per square inch. The consumption of petroleum is as low as 0.15 oz. per hour per candle of light intensity in the mantle. The intensity of the mantle flame varies from 400 candles in the case of 30 mm. diameter mantles to over 1200 candles with 55 mm. mantles. Experimental burners similar to those described have been constructed by the Trinity House and by the Irish Lighthouse Board with satisfactory results.

The following table (prepared by Baron Q. de Rochemont) gives the intrinsic brightness in a horizontal direction of various lighthouse illuminants employed in France. The values are expressed in carrels (9.5 candles) per centimetre of the mean horizontal focal plane of the luminous source:—

1 wick French mineral oil burner . . .	0.35 carrels
2 " " " " . . .	0.50 "
3 " " " " . . .	0.80 "
4 " " " " . . .	0.95 "
5 " " " " . . .	1.10 "
6 " " " " . . .	1.18 "
Incandescent lighting with compressed oil gas . . .	2.00 "
Incandescent lighting with petroleum vapour . . .	2.50 "
Incandescent lighting with acetylene . . .	4.00 "
Crater of the electric arc . . .	900.00 "

The luminous intensity of a beam from a dioptric apparatus is, *ceteris paribus*, proportional to the intrinsic brightness of the luminous source of flame, and not to the total luminous intensity. The intrinsic brightness of the flame of oil lamps increases only slightly with their focal diameter, consequently while the consumption of oil increases, the efficiency of the burner for a given apparatus decreases. The illuminating power of the condensed beam can only be improved to a slight extent, and, in fact, is occasionally decreased, by increasing the number of wicks in the burner. The same argument applies to the case of multiple ring and multiple jet gas burners, which, notwithstanding their large total intensity, have comparatively small intrinsic brightness.

Incandescent Oil Gas Burners.—It has been mentioned that incandescence with low-pressure coal gas produces flames of comparatively small intrinsic brightness. Coal gas cannot be compressed beyond a small extent without considerable injurious condensation and other accompanying evils. Recourse has therefore been had to compressed oil gas, which is capable of undergoing compression to 10 or 12 atmospheres without detriment, and can conveniently be stored in portable reservoirs. The burner employed resembles the ordinary Bunsen burner with incandescent mantle, and the rate of consumption of gas is 27.5 cubic inches per hour per candle. A reducing valve is used for supplying the gas to the burner at constant pressure. The burners can be left for even the whole night without attention. The system was adopted first in France, where it is installed at eight lighthouses, among others the Ar'men Rock light, and has been extended to other parts of the world, including several stations in Scotland. The mantles used in France are of 30 mm. diameter, and occasionally of larger dimensions. The 30 mm. mantle gives a candle-power of 400.

The use of oil gas necessitates the erection of gasworks at the lighthouse, or its periodical supply in portable reservoirs from a neighbouring station. A complete gasworks plant costs about £800. The annual expenditure for gas lighting in France does not exceed £72 where works are installed, or £32 where gas is supplied from elsewhere. In the case of petroleum vapour lighting the annual cost amounts to about £26.

Acetylene.—The high illuminating power and intrinsic brightness of the flame of acetylene makes it a very suitable illuminant for lighthouses, provided the difficulties attending its use can be overcome. At Grangemouth an unattended 21-day beacon has been illuminated by an acetylene flame for some time, and with considerable success. Acetylene has been used also in the United States, Germany, the Argentine, China, &c., for lighthouse and beacon illumination. Many buoys and beacons on the German and Dutch coasts have been supplied with oil gas mixed with 20 per cent. of acetylene, thereby obtaining an increase of over 100 per cent. in illuminating intensity. In France an incandescent burner consuming acetylene gas mixed with air has been installed at the Chassiron lighthouse (1902), the flame intensity being 1300 candles with a 55 mm. mantle. The French Lighthouse Service has perfected an incandescent acetylene burner with a 55 mm. mantle having an intensity of over 2000 candle-power, with intrinsic brightness of 60 candles per square centimetre.

4. Unattended Lights and Beacons.

Until recent years no unattended lights were in existence. The introduction of Pintsch's gas system in the early 'seventies provided a means of illumination for beacons and buoys of which large use has been made. Other illuminants are also in use to a limited extent.

Unattended Electric Lights.—In 1884 an iron beacon lighted by an incandescent lamp supplied with current from a secondary battery was erected on a tidal rock near Cadiz. A 28-day clock was arranged for eclipsing the light between sunrise and sunset and automatically cutting off the current at intervals to produce an occulting characteristic. Several small dioptric apparatus illuminated with incandescent electric lamps have been made by the firm of Barbier of Paris, and supplied with current from batteries of Daniell cells, with electric clockwork mechanism for occulting the light. These apparatus have been fitted to beacons

and buoys, and are generally arranged for switching off the current during the daytime. They run unattended for periods up to two months. Two separate lenses and lamps are usually provided, with lamp changer, only one lamp being in circuit at a time. In the event of failure in the upper lamp of the two the current automatically passes to the lower lamp.

Oil Gas Beacons.—In 1881 a beacon automatically lighted by Pintsch's compressed oil gas was erected on the river Clyde, and many of these structures have since been installed in Great Britain, America, and other parts of the world. The gas is contained in an iron or steel reservoir placed within the beacon structure, and is refilled by means of a flexible hose on the occasions of the periodical visits of the light tender. The beacons, which remain illuminated for periods up to three months, are charged to five atmospheres, the pressure in the storage receiver on the tender being greater. Many lights are provided with occulting apparatus actuated by the gas passing from the reservoir to the burner automatically cutting off and turning on the supply. The Garvel beacon (1899) on the Clyde is shown in Fig. 12. The burner has seven jets, and is occulting.

Lindberg Lights.—In 1881-82 several beacons lighted automatically by volatile petroleum spirit on the Lindberg-Lyth and Lindberg-Trotter systems were established in Sweden. Many lights of this type were subsequently placed in different parts of the world. The volatile spirit lamp burns day and night. Occultations are produced by a screen or series of screens rotated round the light by the ascending current of heated air and gases from the lamp acting upon a horizontal fan. The speed of rotation of the fan cannot be accurately adjusted, and the times of occultation therefore are liable to slight variation. The lights run unattended for periods up to fourteen or twenty-one days.

Benson-Lee Lamps.

—An improvement upon the foregoing was the Benson-Lee lamp, in which a similar occulting arrangement is often used, but the illuminant is paraffin consumed in a special burner having carbon-tipped wicks which require no trimming. The flame intensity of the light is greater than that of the burner consuming light spirit. The introduction of paraffin also avoids the danger attending the use of the more volatile spirit. Twenty-one of these lights are in use on the Scottish coast, and many in other parts of Great Britain, America, Canada, and other countries.

Permanent Wick Lights.—About 1891 the French Lighthouse Service introduced petroleum lamps consuming ordinary high-flash lighthouse oil, and burning without attention for periods of several months. The burners are of special construction, provided with a very thick wick, which is in the first instance treated in such a manner as to cause the formation of a deposit of carbonized tar on its exposed upper surface. This crust prevents further charring of the wick after ignition, the oil becoming vaporized from the under side of the crust. Many fixed, occulting, and flashing lights fitted with these burners have been established in France, and several in other countries. In the case

Crooked River . .	St. George's Sound, Florida	2 flash	10	1/10	18,000	250	..	do.	1 wick	62	115	1895	Mercury rotation; one group of 2 lenses, each 123°, reinforced by a mirror of 90°.

of the occulting types a revolving screen is placed around the burner and is carried upon a miniature mercury float. The rotation is effected by means of a small Gramme motor on a vertical axis fitted with a speed governor, and supplied with current from a battery of primary cells. The oil reservoir is placed in the upper part of the lantern and connected with the burner by a tube, to which is fitted a constant level regulator for maintaining the burning level of the oil at a fixed height. In the flashing or revolving light types the arrangement is generally similar, the lenses being revolved upon a mercury float which is rotated by the electric motor. In the flashing apparatus recently established at Saint-Marcouf, the beam intensity is 1000 candle-power, and it is capable of running unattended for three months. The electric current employed for rotating the apparatus is supplied by four Lalande and Chaperon primary cells, coupled in series, each giving about 0.15 amperes at a voltage of 0.65. The power required to work the apparatus is at the maximum about 0.165 ampere at 0.75 volt, the large surplus of power which is provided for the sake of safety being absorbed by a brake or governor connected with the motor.

Wigham Beacon Lights.—Mr Wigham has introduced an oil lamp for beacon and buoy purposes consisting of a vertical con-

tainer filled with ordinary mineral oil or paraffin, and carrying a roller immediately under the burner case, over which a long flat wick passes. One end of the wick is attached to a float which falls in the container as the oil is consumed, automatically drawing a fresh portion of the wick over the roller. The other end of the wick is attached to a free counterweight keeping it taut. The oil burns from the convex surface of the wick as it passes over the roller, a fresh portion being constantly passed under the action of the flame. The light is capable of burning without attention for thirty days. These lights are also fitted with occulting screens on the Lindberg system. The candle-power of the flame is small.

5. *Light-vessels.*

The earliest light-vessel placed in English waters was that at the Nore in 1732, and before the end of the 18th century several more such ships were in use. Of modern light-vessels, many are built entirely of wood, others are composite, and some of iron. The wood and composite ships are sheathed with Muntz metal. Composite built vessels are considered most suitable for the service. The

FIG. 18.—Sandettié Lightship.

length of English light-vessels varies from 80 to 105 ft., with beam of from 20 ft. to 23 ft., the tonnage ranging from 155 to 265 tons. The lanterns used in modern English light-vessels and others of the same class are 8 ft. in diameter, circular in form, with glazing 4 ft. in height. They are annular in plan, surrounding the mast of the vessel upon which they are hoisted for illumination; they are lowered to the deck level during the day. Of the eighty-four light-vessels in British waters, including some few unattended light-vessels, eleven are in Ireland and five in Scotland. The others are on the coast of England and Wales. In the United States there are thirty-two light-vessels on the Atlantic seaboard and three on the Pacific coast. At the present time there are nearly 700 light-vessels in service throughout the world. The illuminating apparatus for almost all light-vessels is of catoptric form, the more modern vessels being fitted with a series of 21 in. or 24 in. silvered parabolic reflectors, having 1, 2, or 3-wick mineral oil burners in focus. The reflectors and lamps are hung in gimballs to preserve the horizontal direction of the beams.

The following table gives the intensity of beam obtained by means of two types of reflector:—

21-inch Trinity House Parabolic Reflector.

Burners—	Wick	Type	Service Intensity of Beam. Candles.
1	"	"	2715
2	"	(catoptric)	4004
2	"	(dioptric)	5722
3	"	"	7528

24-inch Northern Lighthouse Board Parabolic Reflector.

Burners—	Wick	Type	Service Intensity of Beam. Candles.
1	"	"Doty"	2177
1	"	"Douglass"	4293
2	"	(catoptric)	4265
2	"	(dioptric)	7231

In revolving flashing lights two or more reflectors are arranged in parallel in each face. Three, four, or more faces or groups of mirrors are arranged around the lantern in which they revolve, and are carried upon a turntable rotated by clockwork. The intensity of the flashing beam is therefore equivalent to the combined intensities of the beams emitted by the several mirrors in each face. Group flashing characteristics can be produced by special arrangements of the reflectors. The two most powerful light-vessel lights in the British Isles are the *Sparn* and *Swin Middle*, the latter at the entrance to the Thames, each having a flash intensity of 20,000 candles. At the *Swin Middle* also was placed the first revolving lightship light in 1837.

Fog signals, where provided for light-vessels, are generally in the form of reed-horns or sirens, the smaller reed-horns being of the manual type. In the Trinity House Service many vessels are provided with steam plant for driving the air compressors. Oil engines have been recently introduced for this purpose. The approximate cost of a modern type of Trinity House light-vessel with steam power compressed-air siren is £16,000. The cost of a similar vessel with oil engines is £15,200.

Electrical Illumination.—An experimental installation of electric light was placed in one of the Mersey light-vessels in 1886 by the Mersey Docks and Harbour Board, but unfortunately proved unsuccessful. The United States Lighthouse Board in 1892 constructed a light-vessel provided with a powerful electric light, and moored her on the Cornfield Point station at Long Island Sound. This vessel was subsequently placed off Sandy Hook (1894). Four other light-vessels have since been provided with incandescent electric lights—either with fixed or occulting characteristics—in the United States, at Nantucket Shoals (1896), Fire Island (1897), Diamond Shoals (1898), and Overfalls Shoal (1901).

Gas Illumination.—In 1896 the French Lighthouse Service completed the construction of a steel light-vessel (the *Talais*), which was ultimately placed at the mouth of the Gironde. The construction of this vessel was the outcome of a long series of experiments carried out with a view to (1) regulate the stability of a light-vessel by avoiding all synchronism between its period of oscillation and that of the waves; (2) reduce the vessel's oscillations by the employment of main and bilge keels of great depth; (3) produce an efficient light-vessel at moderate cost, and lit by a dioptric flashing light with incandescent oil gas burners. The construction of the *Talais* was followed by that of a second and larger vessel, the *Snowy*, on similar lines, having a length of 65 ft. 6 ins., beam 20 ft., and a draught of 12 ft., with a displacement of 130 tons. The cost of this vessel complete with optical apparatus and gas holders, with accommodation for three men, was approximately £5000, and the annual cost of upkeep is stated to be £400. The candle-power of the beam is 35,000 candles. The vessel was built in 1898-99. A third vessel was constructed in 1901-02 for the Sandettié bank on the general lines adopted for the preceding examples of her class, but of the following increased dimensions: Length, 115 ft.; width at water line, 20 ft. 6 ins.; and draught, 15 ft., with a displacement of 342 tons (Fig. 13). Accommodation is provided for a crew of eight men. The optical apparatus (Fig. 14) is dioptric, consisting of four panels of 250 mm. focal distance, carried upon a "Cardan" joint below the lens table, and counterbalanced by a heavy pendulum weight. The apparatus is revolved by clockwork and illuminated by compressed gas with incandescent mantle. The candle-power of the beam is 35,000. The gas is contained in three reservoirs placed in the hold. The apparatus is contained in a 6 ft. lantern constructed at the head of a tubular mast 2 ft. 6 ins. diameter. A powerful siren is provided, with steam engine and boiler for working the air compressors. The total cost of the vessel, including fog signal and optical apparatus, was £13,000.

FIG. 14.—Lantern of Sandettié Lightship.

Unattended Light-vessels.—In 1881 an unattended light-vessel, illuminated with Pintsch's oil gas, was constructed for the Clyde, and is still in use at the Garvel Point. The light is occulting, and is shown from a dioptric lens fitted at the head of a braced iron lattice tower 30 ft. above water level. The vessel is of iron, 40 ft. long, 12 ft. beam, and 8 ft. deep, and has a storeholder on board containing oil gas under a pressure of six atmospheres capable of maintaining a light for three months. A similar vessel is placed off Calshot Spit in Southampton Water, and several have been constructed for the French Lighthouse Service. The latter are provided with deep main and bilge keels

similar to those adopted in the larger French gas-illuminated vessels. In 1901 a light-vessel 60 ft. in length was placed off the Otter Rock on the west coast of Scotland: it is constructed of steel, 24 ft. beam, 12 ft. deep, and draws 9 ft. of water (Fig. 15). The focal plane is elevated 25 ft. above the water line, and the lantern is 6 ft. in diameter. The optical apparatus is of 500 mm. focal distance, and hung in gimbals with a pendulum balance and "Cardan" joint as in the Sandettié light-vessel. The illuminant is oil gas, with an occulting characteristic. The storeholder contains 10,500 cub. ft. of gas at eight atmospheres, sufficient to supply the light for ninety days and nights. A bell is provided, and is struck both by clappers moved by the roll of the vessel and by means of an automatic striking gear actuated by the gas on its passage to the burner. Thus the due action of the bell can be depended upon even in calm weather. The cost of the vessel complete was £2979.

Electrical Communication of Light-vessels with the Shore.—Experiments were instituted in 1886 at the *Sunk* light-vessel off the Essex coast for maintaining telephonic communication with the shore by means of a submarine cable 9 miles in length. The cable was landed at Walton-on-the-Naze. Great difficulties were experienced in maintaining communication during stormy weather, breakages in the cable being frequent. These difficulties have subsequently been overcome by the employment of larger vessels and special moorings. In addition, pile lighthouses and isolated

FIG. 15.—Otter Rock Light-vessel.

rock and island stations have been placed in electrical communication with the shore. The Fastnet lighthouse has been electrically connected with the shore by means of a non-continuous cable, it being found impossible to maintain a continuous cable in shallow water near the rock owing to the heavy wash of the sea. A copper conductor is carried down from the tower to below low-water mark, and is separated from the cable proper laid on the

rock and island stations have been placed in electrical communication with the shore. The Fastnet lighthouse has been electrically connected with the shore by means of a non-continuous cable, it being found impossible to maintain a continuous cable in shallow water near the rock owing to the heavy wash of the sea. A copper conductor is carried down from the tower to below low-water mark, and is separated from the cable proper laid on the

bed of the sea in a depth of 13 fathoms by a distance of about 100 ft. The lighthouse is similarly connected to earth on the opposite side of the rock. The conductor terminates in a large copper plate, and to the cable end is attached a copper mushroom. Weak currents are induced in the lighthouse conductor by the main current in the cable, and messages can be received in the tower by the help of electrical relays.

The possibilities of ætheric communication between isolated lighthouses and lightships and the shore are as yet undeveloped. It is probable that the solution of the difficulties now attending the maintenance of submarine communication in such cases will be found in some adaptation of the Marconi or other similar system. (See TELEGRAPHY, WIRELESS.)

6. Illuminated Buoys.

The general question of buoying of coasts, rivers, and estuaries has been dealt with in the article Buoy. Pintsch's oil gas has been in use for the illumination of buoys since 1878. In 1883 an automatic occulter was perfected, worked by the gas passing from the reservoir to the burner. The lights placed on these buoys burn continuously for three or more months, and the buoys and lanterns are made in various forms and sizes. The spar buoy (Fig. 16) is sometimes adopted for situations where strong tides or currents have to be contended with. Oil gas lights are frequently fitted to Courtney whistling buoys and to bell buoys. A bell clapper for buoys has been introduced worked automatically by the gas as in the case of the Otter Rock light-vessel bell. One form of clapper actuated by the roll of the buoy (shown in Fig. 17) consists of a hardened steel ball placed in a horizontal phosphor-bronze cylinder provided with rubber buffers. Three of these cylinders are arranged around the mouth of the bell, which is struck by the balls rolling backwards and forwards as the buoy moves.

In the ordinary type of gas-buoy lantern the burner employed is either of the multiple-jet type or an Argand ring of 18 mm. diameter. It has been found impracticable to use incandescent mantles for buoy lights. The lenses employed are of cylindrical dioptric fixed-light form, 100 mm. to 300 mm. diameter. Some of the largest types of gas-buoy in use on the French coast have an elevation from water level to the focal plane of over 26 feet, with a beam intensity of more than 200 candles. Oil gas forms the most trustworthy and efficient illuminant

FIG. 16.—Spar Gas Buoy.

for buoy purposes yet introduced. The system has been largely adopted by lighthouse and harbour authorities,

and there are now some 1000 buoys fitted with these apparatus, in addition to 250 beacons, light-vessels, and boats. Several buoys have been fitted with electric light, both fixed and occulting, similar to those designed for

FIG. 17.—Buoy Bell.

beacon purposes. Seven electrically lit spar-buoys were laid down in the Gedney Channel, New York Lower Bay, in 1888. These were illuminated by 100 candle-power Swan lamps with continuous current supplied by cable from a power station on shore. The wear and tear of the cables has caused considerable trouble and expense. In 1894 alternating current was introduced and ten buoys lighted. These are still in service. Wigham's oil lamps have also been in some cases fitted to buoys.

7. Fog Signals.

The introduction of coast fog signals is of comparatively recent date. They were until the middle of the 19th century practically unknown except so far as a few isolated bells and guns were concerned. The increasing demands of navigation, and the application of steam power to the propulsion of ships resulting in an increase of their speed, drew attention to the necessity of providing suitable signals as aids to navigation during fog and mist. In times of fog the mariner can expect no certain assistance from even the most efficient system of coast lighting, since the beams of light from the most powerful electric lighthouse are frequently entirely dispersed and absorbed by the particles of moisture forming a sea fog of even moderate density, at a distance of less than a quarter of a mile from the shore. The careful experiments and scientific research which have been devoted to the subject of coast fog-signalling have produced much that is useful and valuable to the mariner, but unfortunately the practical results so far have not been so satisfactory as might be desired, owing to (1) the very short range of the most powerful signals yet produced under certain unfavourable acoustic conditions of the atmosphere, (2) the difficulty experienced by the mariner in judging at any time how far the atmospheric conditions are against him in listening for the expected signal, and (3) the difficulty in locating the position of a sound signal by phonic observations.

Bells and gongs are the oldest and, generally speaking, the least efficient forms of fog signals. Under very favourable

acoustic conditions, however, the sounds may be audible at considerable ranges. On the other hand, the 2-ton bells formerly at the Eddystone have been inaudible at distances of a few hundred yards. The 1893 United States trials showed that a bell weighing 4000 lb struck by a 450 lb hammer was heard at a distance of 14 miles across a gentle breeze and at over 9 miles against a 10-knot breeze. Bells are frequently used for beacon and buoy signals, and in some cases at isolated rock and other stations where there is insufficient accommodation for sirens and horns. In the Trinity House Service their use is, generally speaking, restricted to these cases, but in other countries they are more frequently employed. Gongs, usually of Chinese manufacture, have been in use at many English lightships until quite recently, and also at other stations. In the Trinity House Service these have been superseded by more powerful sound instruments.

Explosive Signals.—Guns were long used at many lighthouse and light-vessel stations in England, but the Trinity House has substituted other explosive or wind signals for all formerly employed. Several guns are still in use as fog signals at Irish lighthouses and light-vessels, and in many instances abroad. No explosive signals are now in use on the coast of the United States. In 1878 sound rockets charged with gun-cotton were first used at Flamborough Head, and were soon afterwards supplied to many other stations. The nitrated gun-cotton or tonite signals now generally used in preference to all other explosive signals are made up in 4 oz. charges and hung at the end of an iron jib or pole attached to the lighthouse lantern or other structure, and fired by means of a detonator and electric spark. These can be discharged within 12 ft. of a structure without danger. The cartridges may be stored for a considerable period without deterioration and with safety. This form of signal is now very generally adopted for rock and other stations in Great Britain, Canada, Newfoundland, northern Europe, and other parts of the world; one type will be noticed in the illustration of the Bishop Rock lighthouse, attached to the lantern (Fig. 2).

Whistles.—Whistles, whether sounded by air or by steam, are not used in Great Britain, except in two instances of harbour signals under local control. It has been objected that their sound has too great a resemblance to steamers' whistles, and they are wasteful of power. In the United States and Canada they have been, however, largely used. The whistle usually employed consists of a metallic dome or bell against which the high-pressure steam impinges. Rapid vibrations are set up both in the metal of the bell and in the internal air, producing a shrill note. The Courtney buoy whistle, already referred to, is an American invention, and many of these instruments are in use in the United States, France, Germany, and elsewhere.

Reed-Horns.—These instruments in their original form were the invention of Daboll, an experimental horn of his manufacture being tried in 1851 by the United States Lighthouse

Board. In 1862 the Trinity House adopted the instrument for seven land and light-vessel stations. For compressing air for the reed-horns as well as sirens, caloric, steam, gas, and oil engines have been variously used, according to local circumstances. The reed-horn was much improved by the late Professor Holmes, and many examples from his design are now in use in England and America. At the Trinity House experiments with fog signals at St Catherine's (1901) several types of reed-horn were experimented with. The best of them was the "Stentor" horn, which ranked second only to the siren instruments under trial. The working pressure is 120 lb per square in., and the nickel-steel reed 4½ in. long by 1½ in. wide. The reed made 265 vibrations per second, and the instrument consumed 2 cubic feet of air (measured at atmospheric pressure) per second of blast. The Trinity House Service horn with a somewhat smaller reed also gave satisfactory results, blowing at 15 lb pressure with a consumption of .67 cubic feet per second and 397 vibrations. A small manual horn of the Trinity House type consumes .67 cubic feet of air at 5 lb pressure, and of its class is about the most satisfactory instrument yet produced. The horns or trumpets are of brass. Reed-horns, either power-driven or of the manual pattern, are in use in many Trinity House light-vessels, and are also used in most other lighthouse services. An experimental reed-horn has been recently placed upon an isolated beacon near Vancouver, the reed of which is actuated automatically by electric current conveyed by a cable from a station on shore.

Sirens.—Undoubtedly the most powerful and efficient of all wind fog-signals is the siren. The principle of this instrument may be briefly explained as follows:—It is well known that if the tympanic membrane is struck periodically and with sufficient rapidity by air impulses or waves, a musical sound is produced. Robinson was the first to construct an instrument by which successive puffs of air under pressure were ejected from the mouth of a pipe. He obtained this effect by using a stop-cock revolving at high speed in such a manner that 720 pulsations per second were produced by the intermittent escape of air through the valves or ports, a smooth musical note being given. Cagniard de la Tour first gave such an instrument the name of siren, and constructed it in the form of an air chamber with perforated lid or cover, the perforations being successively closed and opened by means of a similarly perforated disc fitted to the cover and revolving at high speed. The perforations being cut at an angle, the disc was self-rotated by the oblique pressure of the air in escaping through the slots. Dové and Helmholtz introduced many improvements, and Brown of New York patented about 1870 a steam siren with two discs having radial perforations or slots. The cylindrical form of the siren now generally adopted is due to Mr Slight, who used two concentric cylinders, one revolving within the other, the sides being perforated with vertical slots. To him is also due the centrifugal governor largely used to

TABLE IV.

regulate the speed of rotation of the siren. Over the siren mouth is placed a conical trumpet to collect and direct the sound in the desired direction. In the English service these trumpets are generally of considerable length vertically, with bent top and bell mouth. Those at St Catherine's are of cast iron with copper bell mouth, and have a total axial length of 22 ft. They are 5 in. in diameter at the siren mouth, the bell mouth being 6 ft. in diameter. At St Catherine's the sirens are two in number, 5 in. in diameter, being sounded simultaneously, and in unison. Each siren is provided with ports for producing a high note as well as a low note, the two notes being sounded in quick succession once every minute. The trumpet mouths are separated by an angle of 120° between their axes. This double form has been adopted in certain instances where the angle desired to be covered by the sound is comparatively wide. In

Scotland the cylindrical form is used generally, either automatically or motor-driven. By the latter means the admission of air to the siren can be delayed until the cylinder is rotating at full speed, and a much sharper sound is produced than in the case of the automatic type. The Scottish trumpets are frequently constructed so that the greater portion of the length is horizontal. The Girdleness trumpet has an axial length of 16 ft., 11 ft. 6 in. being horizontal. The trumpet is capable of being rotated through an angle as well as dipped below the horizon. It is of cast iron, no bell mouth is used, and the conical mouth is 4 ft. in diameter. In France the sirens are cylindrical and very similar to the English self-driven type. The trumpets have a very short axial length, 4 ft. 6 in., and are of brass placed vertically, with bent bell mouth. Steam has been abandoned in France for working sirens, and all are now supplied with air

at a pressure of 28 lb per square inch. The Trinity House has recently reintroduced the use of disc sirens, with which experiments are still being carried out. The new Casquets siren has discs 7 in. in diameter and is motor driven; satisfactory results have been obtained. For light-vessels and rock stations where it is desired to distribute the sound equally in all directions the mushroom-head trumpet is occasionally used. The Casquets trumpet of this type is 22 ft. in length, of cast iron, with a mushroom top 6 ft. in diameter. In cases where neither the mushroom trumpet nor the twin siren is used, the single bent trumpet is arranged to rotate through a considerable angle. Table IV. gives particulars of a few typical sirens of the most recent form.

Since the first trial of the steam siren at the South Foreland in 1873 a very large number of these instruments have been established in Great Britain both at lighthouse stations and on board light-vessels. In all cases in Great Britain and France they are supplied with air compressed by steam or other mechanical power. In America and some other countries steam sirens are also in use.

The St Catherine's Experiments.—Extensive trials were carried out during 1901 by a committee of the Trinity House at St Catherine's lighthouse, Isle of Wight, with several types of sirens and reed-horns. The committee also experimented with several forms of trumpet, including some elliptical ones, the long axis being placed vertically. The conclusions of the committee may be briefly enumerated as follows:—(1) When a large arc requires to be guarded two fixed trumpets suitably placed are more effective than one large trumpet capable of being rotated. (2) When the arc to be guarded is larger than that effectively covered by two trumpets, the mushroom-head trumpet is a satisfactory instrument for the purpose. (3) A siren rotated by a separate motor yields better results than when self-driven. (4)

No advantage commensurate with the additional power required is obtained by the use of air at a higher pressure than 25 lb per square inch. (5) The number of vibrations per second produced by the siren or reed should be in unison with the proper note of the associated trumpet. (6) When two notes of different pitch are employed, the difference between these should, if possible, be an octave. (7) For calm weather a low note is more suitable than a high note, but when sounding against the wind and with a rough and noisy sea a high note has the greater range. (8) From causes which cannot be determined at the time or predicted beforehand, areas sometimes exist in which the sounds of fog signals may be greatly enfeebled or even lost altogether. This effect was more frequently observed during comparatively calm weather and at no great distance from the signal station. (It has often been observed that the sound of a signal may be entirely lost within a short distance of the source, while heard distinctly at a greater distance and at the same time.) (9) The siren was the most effective signal experimented with; the reed-horn, although inferior in power, is suitable for situations of secondary importance. (No explosive signals were under trial during the experiments.) (10) A fog signal, owing to the uncertainty attending its audibility, must be regarded only as an auxiliary aid to navigation which cannot at all times be relied upon.

The following table (V.) gives the total numbers of fog signals of each class in use on 1st January 1902 in several countries. When two kinds of signals are employed at any one station, one being subsidiary, the latter is omitted from the enumeration. Buoy and unattended beacon bells and whistles are also omitted, but some local port and harbour signals not under the immediate jurisdiction of the various lighthouse boards are included, more especially in Great Britain.

8. *Lighthouse Administration.*

Most countries possess organized and central authorities responsible for the installation and maintenance of coast lights and fog signals, buoys and beacons.

United Kingdom.—In England the Corporation of Trinity House, or according to its original charter, "The Master, Wardens, and Assistants of the Guild, Fraternity, or Brotherhood of the most glorious and undivided Trinity and of St Clement, in the parish of Deptford Strond, in the county of Kent," existed in the reign of Henry VII. as a religious house, with certain duties connected with pilotage, and was incorporated during the reign of Henry VIII. In 1565 it was given certain rights to maintain beacons, &c., but not until 1680 did it own any lighthouses. Since that date it has gradually purchased most of the ancient privately owned lighthouses and has erected many new ones. The Act of 1836 gave the Corporation control of English lights, with certain supervisory powers over the local lighting authorities, including the Irish and Scottish Boards. The Corporation now consists of a master, deputy-master, and 22 elder brethren (10 of whom are honorary), together with a number of younger brethren, who, however, perform no executive duties. In Scotland the lights are under the control of the Commissioners of Northern Lighthouses, incorporated in 1798. There are several local light boards in Scotland, the principal being the Clyde Lighthouse Trustees. The lighting of the Irish coast is in the hands of the Irish Lights Board, though formerly an ancient corporation, the Dublin Ballast Board, had control. The three lighthouse boards of the United Kingdom are subordinate to the Board of Trade, which controls all finances. The coast and harbour lights of Great Britain and Ireland are upwards of 1000 in number, with over 215 fog signals.

United States.—The United States Lighthouse Board was constituted by Act of Congress in 1852. The Secretary of the Treasury is the *ex-officio* President. The Board consists of two officers of the navy, two engineer officers of the army, and two civilian scientific members, with two secretaries, one a naval officer, the other an officer of engineers in the army. The members are appointed by the President of the United States. The coast-line

of the States, with the lakes and rivers, is divided into 16 executive districts for purposes of administration.

France.—The Lighthouse Board of France is known as the Commission des Phares, dating from 1792 and remodelled in 1811. It consists of four engineers, two naval officers, and one member of the Institute, one inspector-general of marine engineers, and one hydrographic engineer. The chief executive officers are the Inspector-General of Ponts et Chaussées, who is director of the Board, and another engineer of the same corps, who is engineer-in-chief and secretary. The Board has control of about 700 lights, including those of Corsica, Algiers, &c. A similar system has been established in Spain.

English Colonies.—In Canada the coast lighting is in the hands of the Minister of Marine, and in most other colonies the Public Works Departments have control of lighthouse matters.

Other Countries.—In Denmark, Austria, Holland, and many other countries the Minister of Marine has charge of the lighting and buoying of coasts; in Belgium the Public Works Department.

(W. T. D.)

Liguria, a territorial division of northern Italy, lying between the Ligurian Alps and Apennines on the N. and the Mediterranean on the S., and extending from the frontier of France in the W. to the Gulf of Spezia in the E. It embraces the two provinces of Genoa and Porto Maurizio, which have an area of 2037 square miles. Population (1881), 892,373; (1901), 1,080,944. Its principal products are wheat, maize, wine, oranges, lemons, fruits, olives, and potatoes, though the olive groves are being rapidly supplanted by flower-gardens, to grow flowers for export. Copper and iron pyrites are mined. The principal branches of industry are iron works, foundries, iron shipbuilding, engineering, and boiler works (Genoa, Spezia, Sestri, &c.), the production of cocoons, the manufacture of cottons and woollens. Owing to the sheltered situation and the mildness of their climate, many of the towns along this part of the Italian coast are chosen by thousands of foreigners for winter residence, whilst the Italians frequent them in summer for sea-bathing. The history is comprised under GENOA (*q.v.*) and in the art. LIGURIA (9th edition).

See also RIVIERA; also W. H. BULLOCK HALL, *The Romans on the Riviera and the Rhone* (London, 1898).

Li Hung Chang (1823-1901), Chinese statesman, was born on 16th February 1823 at Hofei, in Anhui. From his earliest youth he showed marked ability, and when quite young he took his bachelor degree. In 1847 he became a *Chinshih*, or graduate of the highest order, and two years later was admitted into the Imperial Hanlin College. Shortly after this the Central Provinces of the Empire were invaded by the Taiping rebels, and in defence of his native district he raised a regiment of militia, with which he did such good service to the Imperial cause that he attracted the attention of Tsêng Kwofan, the generalissimo in command. In 1859 he was transferred to the province of Fuh-kien, where he was given the rank of Taotai, or Intendant of Circuit. But Tsêng had not forgotten him, and at his request Li was recalled to take part against the rebels. Fortunately for him, he found his cause supported by the "Ever Victorious Army," which, after having been raised by an American named Ward, was finally placed under the command of Gordon. With this support Li gained numerous victories over the rebels, ending in the surrender of Soochow and the capture of Nanking. For these exploits he was made governor of Kiangsu, was decorated with a Yellow Jacket, and was created an earl. One incident connected with the surrender of Soochow, however, has left a lasting stain upon his character. By an arrangement with Gordon the rebel Wangs, or princes, yielded the city on condition that their lives should be spared. In spite of the assurance given them by Gordon, Li ordered their instant execution. This breach of faith so aroused Gordon's indignation that he seized a rifle, intending to shoot the falsifier of his word, and would have done so had not Li saved himself by flight. On the suppression of the rebellion (1864) Li took up his

duties as governor, but was not long allowed to remain in civil life. On the outbreak of the Nienfei rebellion (1866) he was ordered again to take the field, and after some misadventures he succeeded in suppressing the movement. A year later he was appointed viceroy of Hukwang, in which post he remained until 1870, when the occurrence of the Tientsin massacre necessitated his transfer to the scene of the outrage. He was, as a natural consequence, appointed to the viceroyalty of the metropolitan province of Chihli, and soon justified his appointment by the energy with which he suppressed all attempts to keep alive the anti-foreign sentiment among the people. For his services in this respect he was made Imperial Tutor and member of the Grand Council of the Empire, and was decorated

LI HUNG CHANG.

(From a photograph by J. Russell and Sons, London.)

with many-eyed peacocks' feathers. To his duties as Viceroy were added those belonging to the Superintendent of Trade, and from that time to the day of his death, with some few intervals of retirement, he practically conducted the foreign policy of the Government. He concluded the Chefoo Convention with Sir Thomas Wade (1876), and thus brought to a close the incident of the murder of Mr Margary in Yunnan; he arranged treaties with Peru and Japan, and he actively directed the Chinese policy in Korea. On the death of the Emperor T'ungchih in 1875 he, by suddenly introducing a large armed force into the capital, effected a *coup d'état* by which the Emperor Kwang Sü was put on the throne under the tutelage of the two Dowager Empresses; and in 1886, on the conclusion of the Franco-Chinese war, he arranged a treaty with France. Li was always strongly impressed with the necessity of strengthening the Empire, and when viceroy of Chihli he raised a large well-drilled and well-armed force, and spent vast sums both in fortifying Port Arthur and the Taku Forts and in increasing the navy. For years he had watched the successful reforms effected in Japan, and had

a well-founded dread of coming into conflict with that empire. But in 1894 events forced his hand, and in consequence of a dispute as to the relative influence of China and Japan in Korea, war broke out. The result proved the wisdom of Li's fears. Both on land and at sea the Chinese forces were ignominiously routed, and in 1895, on the fall of Wei-hai-wei, the Emperor sued for peace. With characteristic subterfuge his advisers suggested as peace envoys persons whom the Mikado very properly and promptly refused to accept, and finally Li was sent to represent his Imperial master at the council which was assembled at Shimonoseki. With great diplomatic skill Li pleaded the cause of his country, but finally had to agree to the cession of Formosa, the Pescadores, and the Liaotung peninsula to the conquerors, and to the payment of an indemnity of 200,000,000 taels. By a subsequent arrangement the Liaotung peninsula was restored to China, in exchange for an increased indemnity. A regrettable incident occurred during the peace discussions at Shimonoseki. As Li was being borne through the narrow streets of the town a would-be assassin fired a pistol point-blank in his face. Happily the wound inflicted was not serious, and after a few days' rest he was able to take up again the suspended negotiations. In 1896 he was appointed to represent the Emperor at the coronation of the Tsar, and on that occasion he visited Germany, Belgium, France, England, and the United States of America. For some time after his return to China his services were demanded at Peking, where he was virtually constituted Minister for Foreign Affairs; but in 1900 he was transferred to Canton as viceroy of the two Kwangs. The Boxer movement, however, induced the Emperor to recall him to the capital, and it was mainly owing to his exertions that, at the conclusion of the outbreak, a protocol of peace was signed in September 1901. For many months the health of the veteran statesman had been failing, and the difficulties he encountered in bringing about the terms of the settlement increased his indisposition. As the autumn advanced his medical advisers recognized that the end was near, and he died on the 7th of November 1901. He left three sons and one daughter. (R. K. D.)

See also CHINA, *History*.

Lille, capital of French Flanders and the department of Nord. It is both a fortified place of the first order and an important industrial and commercial city, situated in a district remarkable for its natural fertility and for the high development of its agriculture. It is at the junction of several important railway lines, 153 miles from Paris. The Deule Canal places the river boats of neighbouring ports and Belgium in communication with the town. Flax-spinning occupies 31 factories, with 205,000 spindles, 12,000 workpeople, and an annual production valued at £2,000,000; cloth, table-linen, damask, ticking, canvas, linen tape, and flax velvet for upholsterers' use are manufactured to the value of £3,200,000 per annum; 15 establishments, employing 3000 workpeople, manufacture flax-thread for sewing and lace-making, valued at £1,200,000 per annum; woollen fabrics represent £160,000 to £200,000 a year; and cotton-spinning and the making of cotton-twist (750,000 spindles) of especially fine quality occupy 10,000 persons, who annually produce £2,000,000 worth of goods. Lille also possesses a very important printing establishment with more than 500 workpeople, a tobacco manufactory (1200 workpeople), and 29 breweries; while chemical, oil and sugar works, bleaching grounds, dye-works, and establishments for the making of machinery employ 12,000 workmen. Great quantities of plant for sugar-works and distilleries, military stores, machinery, and bridges of all kinds are further notable manufactures. Lille is also an interesting

town on account of its art collections, which rank among the richest in France. They are now collected in the Palais des Artes (1888-93). The church of Notre Dame de la Treille, a resort of pilgrims, is the finest in French Flanders. Its construction was resumed in 1892. There is a monument to General Faidherbe, one of Lille's most illustrious sons and a hero of the war of 1870. Population (1886), 143,135; (1901), 215,431.

Lima, a coast department of central Peru, with an area of 14,760 square miles and a population (1896) of 298,106. It is divided into six provinces: Chancay, Lima,—in which is the capital of the republic, the city of Lima, with its suburbs, Chorrillos (15,000), Miraflores (6000), and Barranca (5000),—Cañete, Canta, Huarochiri, and Jauja. The town of Huancavelica, in the sierra, has a population of 8000.

Lima, the capital of Peru, situated on a sloping plain between the Andes and the Pacific, 5 miles inland from the latter, in about 12° S. lat. The national library suffered severely during the Chilian occupation in 1881-83, but was reopened in 1884. The construction of a new school of medicine was begun in the Botanical Garden in 1899. Lima possesses amongst her public institutions a school of mines and engineering (1874), with good collections and laboratories; an institute for the arts and trades; a mint; a naval and military institute; the national museum of Peruvian antiquities; and a geographical society, founded in 1888. The university was attended by 650 students in 1898. The average summer temperature is 84° Fahr.; the average winter temperature, 56°. During the latter season frequent mists make the air chilly and the streets muddy. In spite of a good system of underground drainage and an improved water-supply, Lima is not on the whole a healthy place: fevers, dysentery, and tuberculosis are all prevalent. Population (1891), 103,556; (1900), estimated at 113,000. Many of the well-to-do inhabitants live wholly or in part at Miraflores, 5 miles south of the city, and Chorrillos, 7 miles south of the city, is much visited in summer for sea-bathing. Lima is the commercial as well as the administrative centre of the country, but its foreign trade is conducted through the port of Callao, on the Pacific, 7 miles to the west. In 1900 this port was entered and cleared by an aggregate of 2752 vessels of altogether 1,338,984 tons. The imports consist principally of coal, wheat and flour, rice, machinery, and textiles; and the exports of chemicals, sugar, salt, hides, wool, and groceries. (See further under CALLAO.)

Lima, a city of Ohio, U.S.A., capital of Allen county, on the Ottawa river, at an altitude of 872 feet and at the intersection of six railways. It is in the heart of the great petroleum and natural gas fields of Ohio and Indiana, and is one of the most important points in the country for the storing, refining, and shipping of petroleum. It has also railway repair works and extensive manufactures. It is the seat of Lima College, a Lutheran institution founded in 1893, which in 1899 had a faculty of 11 instructors and was attended by 171 students. Population (1890), 15,981; (1900), 21,723, of whom 1457 were foreign-born and 731 were negroes.

Limasol. See CYPRUS.

Limbourg (Flemish, *Limburg*), a province of Belgium, bordering on the Dutch provinces of Limburg and Brabant and the Belgian provinces of Antwerp, Brabant, and Liège. Its rivers are the Meuse, forming its eastern frontier, and the Demer, falling into the basin of the Scheldt, to the west. Canals serve the purposes both of navigation and irrigation; the canal from Liège to Maastricht is prolonged northwards by the canal from

Maastricht to Bois-le-duc, whence there branches off a junction canal from the Mense to the Scheldt, ending at Antwerp. From this latter, again, are detached a branch to the military camp of Beverloo and another branch to Hasselt. Agriculture is followed by more than a third of the population, the crops consisting more particularly of rye, oats, wheat, barley, and beetroot. Other branches of industry are the distillation of gin from grain, the fattening of cattle, the manufacture of sugar from beetroot, and flour-milling. In 1901 a new coalfield was discovered in the north-east of the province, in the district of La Campine. The province is divided into three administrative arrondissements, the capitals of which are Hasselt (15,000), the capital of the province; Tongres (9350); and Maeseyck. At Bourg-Léopold, in the midst of the vast heaths surrounding this commune, is set up the camp of Beverloo, designed for the instruction of the army. Limbourg is the smallest and one of the least populous of the provinces of Belgium. Its area is 931 square miles, and its population, 206,200 in 1875, was 244,139 in 1901, or 262 inhabitants per square mile, an increase of 18·4 per cent., as compared with a 25 per cent. increase during the same period for the whole of Belgium.

Limburg, the southernmost province of Holland, bordering in the east on Rhenish Prussia and in the south on Belgium. The north and the south of the province present a striking contrast. The south is more elevated, by from 300 to 650 feet, culminating near Vaals at 1056 feet. The rich soil (*loess*) around Maastricht and the coalfields in the neighbourhood of St Pietersberg have furnished a basis for a denser and more prosperous population, reminding one of Belgium rather than of Holland. The north of the province, on the other hand, sandy and covered with heath and fens, except near the Meuse, supports a poor and sparse population, of an aspect like that of North Brabant. Altogether about 40 per cent. of the surface is arable, 13 per cent. forest, 11 per cent. meadow and pasture, and 22 per cent. uncultivated. The Meuse being of too impetuous current in winter, and too shallow in summer, there is nowhere in the province any considerable navigation or commerce. There are stone quarries near Maastricht and at Valkenburg. The output of coal in 1899 was 212,972 metric tons. Population (1899), 286,811.

Limerick, a maritime county of Ireland, province of Munster.

Population.—The area of the administrative county in 1900 was 662,978 acres, of which 160,191 were tillage, 427,367 pasture, 293 fallow, 9069 plantation, 9343 turf bog, 4067 marsh, 24,950 barren mountain, and 27,693 water, roads, fences, &c. The new administrative county, under the Local Government (Ireland) Act, 1898, is identical with the old judicial county. The population in 1881 was 180,632, and in 1891, 158,912, of whom 78,607 were males and 80,305 females, divided as follows among the different religions:—Roman Catholics, 150,789; Protestant Episcopalians, 6673; Methodists, 629; Presbyterians, 426; and other denominations, 395. The decrease of population between 1881 and 1891 was 12·02 per cent. The average number of persons to an acre for the whole county was ·23. Of the total population 117,484 persons inhabited the rural districts, being an average of 129 persons to each square mile under crops and pasture. The population in 1901 was 146,018 (Roman Catholics, 138,693; Protestant Episcopalians, 5777; Methodists, 704; Presbyterians, 400; others, 444), being a decrease of 8·1 per cent. The following table gives the degree of education in 1891 (excluding the city of Limerick):—

	Males.	Females.	Total.	Percentage.			
				R.C.	Pr. Ep.	Presb.	Meth.
Read and write	43,002	41,481	84,483	76·0	92·6	95·9	91·8
Read only	4,052	4,347	8,399	7·7	3·0	2·1	4·7
Illiterate	8,068	9,505	17,573	16·3	4·4	2·0	3·5

The percentage of illiterates among Roman Catholics in 1881 was 24·9. Excluding the city of Limerick, in 1891 there were 12

superior schools, with 426 pupils (Roman Catholics 425 and Protestant 1), and 258 primary schools, with 21,139 pupils (Roman Catholics 20,678 and Protestants 461). The number of pupils on the rolls of the National schools on 31st December 1900 was 25,072, of whom 24,292 were Roman Catholics and 780 Protestants. The following table gives the number of births, deaths, and marriages in various years:—

Year.	Births.	Deaths.	Marriages.
1881	4484	3529	798
1891	3637	2801	692
1900	3289	3053	651

In 1900 the birth-rate per 1000 was 22·5, and the death-rate 20·9; the rate of illegitimacy was 3·9 per cent. of the total births. The total number of emigrants who left the county between 1st May 1857 and 31st December 1900 was 178,036, of whom 90,369 were males and 87,667 females. The chief towns in the county are Limerick, Newcastle, and Rathkeale.

Administration.—The county is divided into two parliamentary divisions, East and West, the number of registered electors in 1901 being respectively 8226 and 8533. The rateable value in 1900 was £539,052. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises eight rural sanitary districts. The city of Limerick constitutes a separate county.

Agriculture.—The following tables give the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1900:—

Year.	Wheat.	Oats.	Barley, Rye, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881	7017	22,808	8012	24,175	5605	4047	114,304	180,468
1891	5066	16,620	1037	18,846	4937	5073	109,624	161,203
1895	2202	16,782	475	16,687	5013	4753	119,497	165,409
1900	2669	12,029	281	14,180	3871	4687	122,624	160,191

In 1900 the total value of the cereal and other crops was estimated at £968,047. The number of acres under pasture in 1881 was 405,483; in 1891, 425,256; and in 1900, 427,367.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Figs.	Goats.	Poultry.
1881	17,426	8,830	203,840	49,644	58,136	9,527	496,888
1891	19,950	10,815	241,911	79,600	58,924	14,356	446,074
1895	20,083	11,612	220,995	54,246	49,063	18,123	463,567
1900	18,342	13,144	232,181	58,334	44,696	15,362	509,739

The number of milch cows in 1891 was 101,652, and in 1900 101,312. It is estimated that the total value of cattle, sheep, and pigs for 1900 was £3,169,587. In 1900 the number of holdings not exceeding 1 acre was 4408; between 1 and 5, 1795; between 5 and 15, 2297; between 15 and 30, 3025; between 30 and 50, 2954; between 50 and 100, 2838; between 100 and 200, 1041; between 200 and 500, 242; and above 500, 33—total 18,633. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901, was 1358, amounting to £768,884. The number of loans for agricultural improvements sanctioned under section 31 of the Land Act, 1881, between 1882 and 1901, was 1105, and the amount issued was £82,330. The total amount issued on loan for all classes of works under the Land Improvement Acts, from the commencement of operations in 1847 to 31st March 1901, was £397,499, the third largest amount in any county.

Fisheries.—In the salmon-fishery district of Limerick 1742 persons were employed in 1900, and the sum of £2315 was paid as licence duty, the largest amount in any fishery district in Ireland. (W. H. Po.)

Limerick, a maritime city, county and parliamentary borough (returning one member), at the head of the estuary of the river Shannon, 120 miles west-south-west of Dublin by rail. It is the most important port on the west coast of Ireland, vessels of 3000 tons being able to discharge at the floating dock. The quays extend for about 1600 yards on each side of the river, and vessels of 600 tons can moor alongside at spring tides. In all 435 vessels (423 British and 12 foreign) of 158,240 tons entered in 1900, while 296 (all British except 4) of 78,860 tons cleared. The value of the foreign and colonial imports,

which included 1,220,600 cwts. of wheat and 915,100 cwts. of maize, was £868,190. In the same year the number of sailing and steam vessels registered in the port was 27, of 1245 tons. Flour-milling is a flourishing industry, and the greater part of the south-west and north-west of Ireland is supplied with flour from Limerick. There is also an extensive trade in bacon, over 10,000 pigs being slaughtered weekly; and the improvement in dairy-farming has led to the establishment of creameries and a large condensed-milk factory. The great Munster fair is held here four times a year. New waterworks were completed at a cost of £70,000. The salmon fisheries on the Shannon are the most valuable in Ireland, and in 1900 gave employment to 1742 persons. In 1898 Limerick was constituted one of the six county boroughs which have separate county councils. The rateable value in 1900 was £69,008. Population (1881), 38,562; (1891), 37,155; (1901), 38,085. In 1891 there were 10 superior schools with 574 pupils (489 Roman Catholics and 85 Protestants), and 44 primary schools with 5577 pupils (5050 Roman Catholics and 527 Protestants). The percentage of illiterates among Roman Catholics was 19.2, as compared with 25.1 in 1881.

Limnology.—In the last quarter of the 19th century the study of lakes made remarkable progress, and was raised to the rank of a special science, mainly by the exertions of Prof. F. A. Forel, to whom is due the generally accepted name limnology. Limnology includes the complete study of lakes, geographical, physical, chemical, and biological, so conducted as to throw light on the mutual relations of all the natural conditions affecting them. The lakes of Europe and of several of the other continents have been investigated with some approach to completeness. Professor Forel has himself produced the standard monograph on the Lake of Geneva, to the investigation of which in all its aspects he has devoted his life. A Hungarian commission has explored Lake Balaton with equal fulness, and the Lake of Constance has been studied by an international committee of the five states which border it. The investigation of lakes has as a rule been entirely neglected by government surveyors, the departments charged with land and marine surveys alike declining to be responsible for the areas covered by fresh water. Hence in most countries private enterprise has endeavoured to fill the gaps on the large-scale maps. Amongst other workers M. André Delebecque in France has surveyed a large number of the lakes of the Alps, Vosges, and Pyrenees; Professor Richter has surveyed many of those of Austria; Drs Geistbeck, Ule, and Halbfass those of Germany; Professor Anuchin several of those in Russia; O. Marinelli in Italy; while some work has also been done on the lakes of Scandinavia and Finland. In Great Britain the lakes of the English Lake District were sounded and mapped by H. R. Mill and E. Heawood in 1893–94, under the auspices of the Royal Geographical Society; and many of the fresh-water lochs in Scotland have been fully mapped by Sir John Murray and F. P. Pullar. After the death, by drowning, of the last-named worker, a scheme was set on foot in his memory by which Sir John Murray undertook, with the support of Mr Laurence Pullar, to complete the study of all the lakes of the British Islands.

In Asia the lakes of Palestine, and some of those in Asia Minor and the Pamirs, have been sounded by travellers, and preliminary observations of much interest have been made in the great lakes of Africa, the survey of Lake Nyasa, indeed, being fairly complete. Of the lakes of Australia, New Zealand, and South America very little is yet known, but those of North America are being gradually surveyed. In the north of the United States

particularly very complete and systematic researches are being made into the geographical and biological nature of the lakes.

Limnology may be looked upon as oceanography in miniature, and its study in many cases throws light on the larger problems of oceanography, which in lakes may be handled almost on the scale of laboratory experiments. But it differs essentially from oceanography on account of the important physical peculiarities of fresh water, and by the immense diversity of the separate objects of study. The ocean is one and uniform, with all its parts in free communication, all at the same level, and affected by the proximity of land only on the margins. Lakes, on the other hand, are diverse and innumerable; they occur at every level, from 1200 feet below that of the sea to over 20,000 feet above it. They are subject to the influence of the land in every part, and each lake, so far as its physical and biological conditions are concerned, is isolated and distinct from every other. Thus every lake has its own clearly-marked individuality, forming a microcosm which must be studied in detail before it can be fully understood. The number of monographs on particular lakes and lake-groups has grown so much in recent years that it is now possible to draw some wide conclusions applicable to all lakes, and thus to afford a surer basis for particular researches. The following are the general considerations set forth by Professor Forel in his *Handbook of Limnology*.

A lake is defined as a depression enclosed by land on every side, and containing standing water which is not in communication with the sea. Tidal lagoons are thus excluded. Lakes are divided into (1) *lakes proper*, which may be of any size if the water be deep enough to prevent the invasion of aquatic plants, (2) *ponds*, which are so shallow that plants may take root on the bottom on any part, and (3) *marshes*, which are ponds almost filled with vegetation.

The geographical conditions which affect a lake are chiefly its position in general, and particularly its latitude and altitude, on which depends the climate, and also to a great degree the character of the organisms living in the water. The area of a lake determines the effect which its waters can exercise upon its banks, as it is only in large lakes that the wind is able to raise waves and currents capable of producing erosion. The depth also exercises an influence on the movement of the waters, and has a bearing on the distribution of life and on the theory of the origin of the lake-basin. If a lake-basin were a uniform funnel-shaped depression, its average depth would be one-third of the maximum, but as a rule a great part of the floor of a lake is a perfectly flat surface of sedimentation, and the average depth is usually one-half, or even a larger fraction, of the maximum. The typical lake-basin has the form of the frustum of an inverted cone. Limnometric functions to which some importance is attached in classifying lakes are the development of the coast-line and the number and size of the islands. With regard to chemical and thermal conditions, the total volume of a lake is important, and the relation of the tributary drainage area to the area of the lake surface affords some clue to the probable variations of volume and consequent changes in level and in temperature, these being in close relation to the volume and variations of the inflowing streams. As to position in a river course, the fact of a stream flowing through a lake, or ending in it, may greatly affect the active or passive migration of aquatic plants and animals.

Meteorological conditions are even more important. The thermal changes of lake-water depend upon the atmospheric temperature almost entirely. Absolute humidity of the atmosphere determines the dew-point, on the relation of which to the temperature of the surface water the occurrence of condensation or evaporation depends. Relative humidity determines the amount of cloud and the frequency of precipitation, the former dictating the amount of solar radiation to the lake in the daytime and of radiation from the lake at night, the latter being vital to the supply of inflowing water. In the extreme case of dry air and great radiation salt lakes with no outlet are produced. Wind produces waves and currents which mix the water, and it also serves as the agent by which a large lake influences the climate of the surrounding

district. The general wind blowing across a lake, or sudden storms descending upon it, are of less interest than the local winds produced by its influence on the atmosphere. Effects analogous to land and sea breezes are produced around large lakes: at night in summer the land breeze blows in towards the centre of the lake, and by day the lake breeze blows outwards towards the land; but in winter the land wind prevails also throughout the day. Local variations of barometric pressure are the cause of the effects known as *seiches*.

It is important to distinguish the different parts of a lake-basin. These typically consist of a flat floor surrounded by a relatively steep slope. The floor and the lower part of the slope form the deep area; the upper part of the slope is the coastal area, and in this we may distinguish the *banks*, which form a ring round the lake and are washed over by the waves in heavy storms; the *beach*, which is intermediate between the banks and the *littoral zone*, or belt in which the action of the waves produces an effect on the bed of the lake.

From whatever causes a lake may arise, the natural processes of its economy, the incoming and outgoing of its affluent and effluent waters, produce changes in its basins—the building of deltas, the scattering of fine sediment over the floor, and the down-cutting of the outlet, all ultimately tending to the extinction of the lake by filling up and natural draining. According to the stage to which these processes have advanced, the lake may be classed as young, mature, old, and finally as dead.

From having been the special study of geologists in its physical aspects, limnology is now rapidly becoming the peculiar study of biologists, and attempts are even being made to limit the meaning of the word to the study of organic life in lakes, which would be denoted more correctly as limno-biology.

Limoges, chief town of department Haute-Vienne, France, 249 miles south-south-west of Paris by rail. It comprises two parts originally distinct—the city occupying the lower slope of the hill, and the town proper the summit. Boulevards now replace the ancient fortifications, and the suburbs are extending. Amongst modern public buildings are the Hôtel de Ville (1882) and the National Establishment of Decorative Art, containing various collections; there is also a statue of Gay-Lussac (1890), besides a monumental fountain (1893). There are about thirty factories for the manufacture of porcelain, and the production averages about £600,000 per annum. This and the cognate industries, together with the working of the quarries and the preparation of kaolin paste for foreign potteries, give employment to about 20,000 persons. The making of boots and shoes and clogs has made great advances as an industry, about 2000 persons being employed in bootmaking and from 300 to 400 in the manufacture of clogs. Population (1881), 55,580; (1891), 60,890; (1901), 83,569.

Limon, or PORT LIMON, the chief Atlantic port of the republic of Costa Rica, Central America, situated on a bay of the Caribbean Sea, 103 miles from the capital, San José, by rail. The first houses were built in 1871. Large expense has been incurred by the authorities in improving the sanitation of the town. The harbour has also been much improved, and is now protected by a sea-wall built along the low-water line. An iron pier affords accommodation for four large ocean steamers, and all that is required to render the port first-class is a breakwater from the harbour to a small island

about 1200 yards distant. There is an excellent water-supply from the hills above the harbour. Almost the entire coffee crop of Costa Rica is sent by rail for shipment at Port Limon to Europe and the United States. The port is now visited by about thirty steamers monthly from the United States, Europe, the Spanish Main, and the West Indian Islands. There are ice factories and a brewery. Population (1897), 4000.

Limoux, chief town of arrondissement, department of Aude, France, 15 miles south-south-west of Carcassonne, on railway to Quillan and on the left bank of the Aude. The town was formerly the fortified capital of the comté of Prasey, and still preserves some vestiges of its ancient ramparts. The St Martin's church is a large Gothic edifice, founded on an earlier Roman one. Two other churches were formerly attached to conventual establishments, and on a hill north of the town is the 14th-century church of Notre Dame de Marceille, with a black marble image of the Virgin. The town has also a general hospital, the asylum for the departments of Aude and Pyrénées-Orientales, and a tribunal of commerce. There is trade in wine, corn, and fodder, besides manufactures of hats and caps: the white wine known as "blanquette de Limoux" is held in high repute. Manganese, building stone, gypsum, and marble are found in the vicinity. Population (1881), 4647; (1891), 4507; (1901), 7045.

Limpopo, a considerable river of South-East Africa, rising on the high plateau of the Southern Transvaal and flowing in a wide semicircular sweep round the northern frontiers of that country, finally entering the Indian Ocean through Portuguese territory in 25¼° S. Surveys of the lower river by Portuguese officers in 1895–96 have shown that this may be utilized as a waterway to the interior by the employment of shallow-draught steamers, at least as far as Gungunyana's ford in 24° 41' S. The bar has been found less dangerous than was once supposed, but at low water (December) navigation is very difficult at certain points on the river, especially at the Ilha Verde in 24° 53½'. Below Gungunyana's ford (which seems itself to be passable) the passage is almost blocked by a bar of hard micaceous clay, through which, however, there is a channel with 2½ feet of water. The extreme high-water level on the lower course is more than 24 feet above that of low water, and when it is reached the whole plain bordering the Limpopo is flooded. At this period water communication seems to be established with the Nkomati river, which is crossed by the Delagoa Bay railway on the Transvaal frontier.

See *Boletim Soc. Geogr. de Lisboa*, xvi. (1897), p. 561, with map, and also map issued by the Ministerio da Marinha, 1897.—DA COSTA. *Gaza*, 1897–98. Lisbon, 1899.—GRANDJEAN in *Bul. Soc. Neuchateloise de Géogr.* 1899. (E. HE.)

Linares, a town of Spain, in the province of Jaen. The population is decreasing somewhat, and was only 35,233 in 1897. The lead mine concessions on the register at the close of 1898 were 1075. Four English companies are desilverizers and smelters as well as manufacturers of lead sheets and pipes, and purchase most of the ore raised. The production in 1898 amounted to 81,250 tons of first-class ore and 20,223 tons of second-class ore. There is active trade in wine, oil (28,300 gallons in 1898), wheat (43,000 bushels), and barley (54,000 bushels). There are many new and handsome buildings, including the town hall, the theatre, casinos, the bull-ring, the savings bank, factories, and mining offices.

Linares, a province of southern Chile, situated between 35° 30' and 36° 30' S. and 70° 30' and 72° W.,

bounded on the N. by the province of Talca, on the S. by that of Ñuble, and on the W. by that of Maule, while on the E. the anticlinal line of the Andes is its border. Its area is 3589 square miles, and in 1895 its population was 101,858. The capital, Linares, has a population of 7331.

Lincoln, a north midland county of England, bounded on the N. by York, on the E. by the North Sea and Norfolk, on the S. by Cambridge, Northampton, and Rutland, and on the W. by Leicester, Nottingham, and York.

Area and Population.—In 1891 the area of the ancient (geographical) county was 1,693,547 acres, and the population 472,878, of whom 233,571 were males and 239,307 females, showing an increase of 2884, or 7 per cent. since 1881, as compared with an increase of 7.7 per cent. in the ten years 1871-81. There were, in 1891, 0.28 persons to an acre and 3.58 acres to a person. In 1901 the population of the ancient county was 498,781. The area of the registration county in 1891 was 1,659,930 acres, and the population 467,281; and in 1901, 492,948, of whom 242,193 were males and 250,755 females. The subjoined table gives particulars of the birth-rate, death-rate, the number of persons married per 1000 inhabitants, and the illegitimacy-rate per 1000 births:—

	1871-80.	1881-90.	1891-98.	1899.
Birth-rate	32.6	30.4	28.4	28.5
Death-rate	18.6	17.5	17.1	17.0
Marriage-rate	14.7	13.6	15.0	17.1
Illegitimacy-rate	62	58	55	57

In 1891 the county contained 1230 persons of Scottish birth, 1454 of Irish birth, and 1295 foreigners. At the same date there were 385 blind persons, 190 deaf and dumb, and 1271 insane.

Administration.—For parliamentary purposes the county is divided into seven divisions, namely, West Lindsey or Gainsborough, North Lindsey or Brigg, East Lindsey or Louth, South Lindsey or Horncastle, North Kesteven or Sleaford, South Kesteven or Stamford, and Holland or Spalding, and the parliamentary boroughs of Boston, Grantham, Grimsby, and Lincoln, each returning one member. The county embraces the three administrative counties of the parts of Lindsey, parts of Kesteven, and parts of Holland, together with the county boroughs of Lincoln and Grimsby. There are six municipal boroughs, Boston, Grantham, Grimsby, Lincoln, Louth, and Stamford. In the parts of Holland the borough of Boston has a separate commission of the peace, and there are two petty sessional divisions. In the parts of Kesteven the boroughs of Grantham and Stamford have each a separate commission of the peace and separate courts of quarter sessions, and there are 4 petty sessional divisions. In the parts of Lindsey the county boroughs of Grimsby and Lincoln have each a separate commission of the peace and a separate court of quarter sessions, whilst the municipal borough of Louth has a separate commission of the peace, and there are 14 petty sessional divisions. The three administrative counties contain respectively 55, 211, and 458 entire civil parishes, the county borough of Grimsby one entire civil parish, and the county borough of Lincoln 18 entire civil parishes; these administrative divisions taken conjointly also embrace 4 other entire civil parishes and parts of 2 others which are situated partly in other administrative counties. The ancient county contains 581 entire ecclesiastical parishes and districts, and parts of 4 others. It is mostly in the diocese of Lincoln, but in part also in the dioceses of Southwell and York.

Education.—There is a diocesan training college for women teachers at Lincoln. The number of elementary schools in the county on 31st August 1900 was 592, of which 132 were board schools and 460 voluntary schools, the latter including 419 National Church of England schools, 20 Wesleyan, 11 Roman Catholic, and 10 British and "other." The average attendance during the year was 56,459 out of 69,437 on the register. The total school board receipts for the year ending 29th September 1900 were £74,074, of which £5383 was the income under the Agricultural Rates Act.

Agriculture.—Since 1880 there has been an increase in the area of the permanent pasture and of the meadow-land. The area devoted to both bare fallows and corn crops has decreased since 1880. The number of acres farmed by tenants was 1,271,244 in 1889, 1,318,631 in 1895, and 1,358,862 in 1900; the number of acres farmed by the owners being 248,444, 199,058, and 159,333 respectively.

The table immediately following shows the areas under the different kinds of crops for the periods named:—

Year.	Area in Cultivation.	Area under Corn Crops.	Area under Green Crops.	Area of Bare Fallow.	Area under Permanent Grass.
1880	1,494,461	611,684	238,239	37,656	...
1885	1,510,615	601,682	233,556	30,816	464,868
1890	1,522,425	586,749	229,319	28,246	487,761
1895	1,517,689	552,017	241,148	27,966	500,742
1900	1,518,195	562,504	249,247	18,388	499,203

The next table shows the numbers of the live stock for the periods named:—

Year.	Cows and Heifers.	Other Cattle.	Total Cattle.	Horses.	Sheep.	Pigs.
1880	53,023	158,339	211,362	64,510	1,444,867	85,116
1885	61,527	170,875	232,402	66,593	1,270,048	93,107
1890	66,076	175,007	241,083	68,201	1,293,152	107,702
1895	61,606	171,776	233,382	72,698	1,161,958	114,278
1900	70,892	186,050	256,942	73,281	1,159,603	102,392

Industries.—In the year 1897, 29,273 persons were employed in factories and workshops, the majority in engineering, agricultural implement, and similar works, namely 13,052, or 44 per cent. of the whole. Next in importance comes the making of clothing, with 2394 persons; then the metal trades, with 2302; and the preparation of food, with 1646. Iron ore (hæmatite) and building stone are the principal products of the mines and quarries, the number of men employed in these and similar occupations in 1900 being 1231. In the same year 1,924,898 tons of iron ore were extracted, also 178,874 tons of clays, 47,147 tons of limestone, 42,917 tons of chalk, and 5797 tons of gravel. In 1895, 926,440 tons of ironstone, freestone, and sandstone, inclusive of Ancaster freestone, were quarried, to the value of £139,142. In 1900 there were 16 blast furnaces operative in the county; these, together with 3 other furnaces in Leicestershire, yielded 388,745 tons of pig-iron.

Authorities.—W. MARRAT, *History of Lincolnshire*, 3 vols. and fragments of vols. iv. and v. (Boston, 1814 et seq.), dealing chiefly with the southern or fen parishes. A list of local monographs, some of them, like Thompson's *Boston*, Oldfield's *Wainfleet*, Stone's *Isle of Axholm*, of great value, is given in an appendix to vols. i. and ii. of *Lincolnshire Notes and Queries* (Horncastle, 1888-91). See further under FENS. (J. T. B.E.)

Lincoln, a parliamentary, county, and municipal borough of England, on the Witham, 130 miles north by west of London by rail. A monument (Decorated) to Bishop Wordsworth was unveiled in the cathedral in 1888, and the chapter-house was restored in 1889. As regards the other churches, the following have been built or rebuilt since 1870: St Faith's, St Matthias's, St Swithin's, and St Mary Magdalene's; and the following have been enlarged or restored: St John's, St Peter's at Gowts, St Peter's in Eastgate, and St Andrew's. The Roman Catholic church of St Hugh's was consecrated in 1893. The old Assembly Rooms now shelter the Lincoln Public Library (1892) of some 7000 volumes. The public institutions include science and art schools; the county gaol; the county pauper lunatic asylum; the high school for girls (1892); the drill hall; new grammar school, the old buildings being given over to the Boys' Middle School. In the year 1884 the Blue Coat School (Christ's Hospital), was closed, its endowments going to the Middle School, and its buildings sold to the Church Institute. In 1884-91 a Roman burial-place, with funeral urns, was brought to light on the site of the old Angel Inn, a Roman altar under St Peter's at Gowts, a fragment of the east town wall, and remains of a Roman villa in Greetwell. In 1884 the county of Nottingham was transferred from this see to the see of Southwell. The municipal borough is governed by a mayor, 6 aldermen, and 18 councillors. Area, 3747 acres. Population (1891), 41,491; (1901), 48,784.

See E. VENABLES and G. G. PERRY, *Diocesan History of Lincoln* (London, 1898); and *Statutes of Lincoln Cathedral*, arranged by H. BRADSHAW and edited by C. WORDSWORTH, 3 vols. (Cambridge, 1898).

Lincoln, a city of Illinois, U.S.A., capital of Logan county, on the Peoria, Decatur, and Evansville, the Illinois S. VI. — 35

Central, and the Chicago and Alton railways, at an altitude of 591 feet. It is in an agricultural and coal-mining region. It is the seat of Lincoln University, a Cumberland Presbyterian institution. Population (1890), 6725; (1900), 8962, of whom 940 were foreign-born and 238 were negroes.

Lincoln, a city of Nebraska, U.S.A., capital of Lancaster county and of the state, at an altitude of 1147 feet. Its site is level and in some parts marshy, and its plan is regular, with broad well-shaded streets. The water-supply and sewerage system are good, and the city is divided into seven wards. Lincoln is at the intersection of five great railway systems, the Burlington and Missouri River, the Chicago, Rock Island and Pacific, the Fremont, Elkhorn and Missouri Valley, the Missouri Pacific, and the Union Pacific; and being the collecting and distributing point for a large area of fertile agricultural lands, it has especial importance as a commercial city. Its manufacturing establishments in 1900 numbered 250, with a total capital of \$2,608,992. They employed 1736 hands (besides 244 salaried officials and clerks), and their product was valued at \$4,105,951. The city has several educational institutions, the principal one being the University of Nebraska, which in 1899 had a faculty of 100 and was attended by 1572 students. Its property was valued at \$2,050,000, and its income was \$199,500. In 1900 the assessed valuation of real property was \$4,144,880, and of personal property \$1,080,884—the former on a basis of about one-fifth and the latter of about one-eighth of the full value. The net debt was \$1,715,860, and the rate of taxation \$77.40 per \$1000. Population (1880), 13,003; (1890), 55,154; (1900), 40,169, of whom 5297 were foreign-born and 814 were negroes.

Lincoln Judgment, The.—In this celebrated ecclesiastical law-suit, the bishop of Lincoln (Dr King) was cited before his metropolitan, the archbishop of Canterbury (Dr Benson), to answer charges of various ritual offences committed at the administration of Holy Communion in the church of St Peter's at Gowts, in the diocese of Lincoln, on 4th December 1887, and in Lincoln Cathedral on 10th December 1887. The promoters were Ernest De Lacy Read, William Brown, Felix Thomas Wilson, and John Marshall, all inhabitants of the diocese of Lincoln, and the last two parishioners of St Peter's at Gowts. The case excited general interest while it was in progress, and it has a permanent importance in two respects. First, certain disputed questions of ritual were legally decided. Secondly, the jurisdiction of the archbishop of Canterbury alone to try one of his suffragan bishops for alleged ecclesiastical offences was considered and judicially declared to be well founded both by the Judicial Committee of Privy Council and by the archbishop of Canterbury with the concurrence of his assessors. The proceedings were begun on 2nd June 1888 by a petition presented by the promoters to the archbishop, praying that a citation to the bishop of Lincoln might issue calling on him to answer certain ritual charges, the nature of which will be stated presently. On 26th June 1888 the archbishop, by letter, declined to issue citation, on the ground that until instructed by a competent court as to his jurisdiction, he was not clear that he had it. The promoters appealed to the Judicial Committee of the Privy Council, to which an appeal lies under 25 Henry VIII. c. 19 for "lack of justice" in the Archbishop's Court.

The matter was heard on 20th July 1888, and on 8th August 1888 the committee decided (i.) that an appeal lay from the refusal of the archbishop to the Judicial Committee, and (ii.) that the archbishop had jurisdiction

to issue a citation to the bishop of Lincoln and to hear the promoters' complaint, but they abstained from expressing an opinion as to whether the archbishop had a discretion to refuse citation—whether, in fact, he had any power of "veto" over the prosecution. The case being thus remitted to the archbishop, he decided to entertain it, and on 4th January 1889 issued a citation to the bishop of Lincoln.

On the 12th February 1889 the archbishop of Canterbury sat in Lambeth Palace Library, accompanied by the bishops of London (Dr Temple), Winchester (Dr Harold Browne), Oxford (Dr Stubbs), and Salisbury (Dr Wordsworth), and the vicar-general (Sir J. Parker Deane) as assessors. The bishop of Lincoln appeared in person and read a "Protest" to the archbishop's jurisdiction to try him except in a court composed of the archbishop and all the bishops of the province as judges. The court adjourned in order that the question of jurisdiction might be argued. This was done on 12th, 13th, 14th, 20th, 21st, 26th, and 27th March 1889, and on the 11th May the archbishop gave judgment to the effect that whether sitting alone or with assessors he had jurisdiction to entertain the charge. On 23rd and 24th July 1889 a further preliminary objection raised by the bishop of Lincoln's counsel was argued. The offences alleged against the bishop of Lincoln were largely breaches of various rubrics in the communion service of the Prayer Book which give directions to the "minister." These rubrics are by the Acts of Uniformity (1 Elizabeth c. 2, and 13 and 14 Charles II. c. 4) made legally binding. But it was argued that a bishop is not a "minister" so as to be bound by the rubrics. The archbishop, however, held otherwise, and the assessors (except the bishop of Salisbury, who dissented) concurred in this decision. At this and subsequent hearings the bishop of Hereford (Dr Atlay) took the place of the bishop of Winchester as an assessor, and the bishop of Rochester (Dr Thorold), originally appointed an assessor, but absent from England at the outset, was present.

The case was heard on its merits on 4th, 5th, 6th, 7th, 20th, 21st, 22nd, and 25th February 1890, before the archbishop and all the assessors, and the archbishop delivered his judgment on 21st November 1890. The alleged offences were eight in number. No facts were in dispute, but only the legality of the various matters complained of. I. The bishop was charged with having mixed water with wine in the chalice during the communion service, and II. with having administered the chalice so mixed to the communicants. It was decided that the mixing of the water with the wine during service was illegal, because an additional ceremony not enjoined in the Prayer Book, but that the administration of the mixed chalice, the mixing having been effected before service, was in accordance with primitive practice and not forbidden in the Church of England. III. The bishop was charged with the ceremonial washing of the vessels used for the holy communion, and with drinking the water used for these ablutions. It was decided that the bishop had committed no offence, and that what he had done was a reasonable compliance with the requirement of the rubric that any of the consecrated elements left over at the end of the celebration should be then and there consumed. IV. The bishop was charged with taking the eastward position (*i.e.*, standing at the west side of the holy table with his face to the east and his back to the congregation) during the ante-communion service (*i.e.*, the part of the communion service prior to the consecration prayer). The rubric requires the celebrant to stand at the north side of the table. A vast amount of research convinced

**Charges
and
decisions.**

the archbishop that this is an intentionally ambiguous phrase which may with equal accuracy be applied to the north end of the table as now arranged in churches, and to the long side of the table, which, in Edward VI.'s reign, was often placed lengthwise down the church, so that the long sides would face north and south. It was therefore decided (one of the assessors dissenting) that both positions are legal, and that the bishop had not offended in adopting the eastward position. V. The bishop was charged with so standing during the consecration prayer that the "Manual Acts" of consecration were invisible to the people gathered round. It should be stated that the courts (see *Ridsdale v. Clifton*, L.R. 1 P.D. 316; 2 P.D. 276) had already decided that the eastward position during the consecration prayer was legal, but that it might not be so used by the celebrant as to conceal the "Manual Acts." The archbishop held that the bishop of Lincoln had transgressed the law in this particular. VI. The bishop was charged with having, during the celebration of holy communion, allowed two candles to be alight on a shelf or retable behind the altar when they were not necessary for giving light. The archbishop decided that the mere presence of two altar candles burning during the service, but lit before it began, was lawful under the First Prayer Book of Edward VI., and has never been made unlawful, and therefore that the bishop was justified in what he had done. VII. The bishop was charged with having permitted the hymn known as *Agnus Dei* to be sung immediately after the consecration of the elements at a celebration of the holy communion. The archbishop decided that the use of hymns in divine service was too firmly established to be legally questioned, and that there was nothing to differentiate the use of this particular hymn at this point of the service from the use of other hymns on other occasions in public worship. VIII. The bishop was charged with making the sign of the Cross in the air with his hand in the benediction and at other times during divine service. The archbishop held that these crossings were ceremonies not enjoined and therefore illegal, and that the bishop had offended in this particular. The judgment confined itself to the declarations of the law which have been summarized, and pronounced no monition or other sentence on the bishop of Lincoln in respect of the matters in which he appeared to have committed breaches of the ecclesiastical law.

The promoters appealed to the Judicial Committee. The bishop did not appear on the appeal, which was therefore argued on the side of the promoters only. The appeal was heard on 10th, 11th, 12th, 15th, and 16th June, and 2nd, 3rd, 7th, and 8th July 1891, before Lords Halsbury, Hobhouse, Esher, Herschell, Hannen, and Shand and Sir Richard Couch, with the bishop of Chichester (Dr Durnford), the bishop of St Davids (Dr Basil Jones), and the bishop of Lichfield (Dr Maclagan) as episcopal assessors. The points appealed were those above numbered II., III., IV., VI., VII. Judgment was given on 2nd August 1892, and the appeal failed on all points. As to II., III., IV., and VII. the Judicial Committee agreed with the archbishop. As to VI. (altar lights) the Judicial Committee held that as it was not shown that the bishop was responsible for the presence of lighted candles, the charge could not be sustained against him, and so dismissed it without considering the general question of the lawfulness of altar lights dealt with in the archbishop's judgment. The Judicial Committee also held that the archbishop was within his right in pronouncing no sentence against the bishop, who, it should be added, conformed his practice to the archbishop's judgment from the date of its delivery.

(L. T. D.)

Lind, Jenny [MADAME LIND-GOLDSCHMIDT] (1820-1887), the famous Swedish singer, born in Stockholm, 6th October 1820, was the child of a lace manufacturer. It was Mlle Lundberg, an opera-dancer, who first discovered her musical gift, and induced the child's mother to have her educated for the stage; during the six or seven years in which she was what was called an "ac-tress pupil," she occasionally appeared on the stage, but in plays, not operas, until 1836, when she made a first attempt in an opera by Lindblad. She was regularly engaged at the opera-house in 1837, and appeared in a great number of parts in pieces that are now forgotten. Her first great success was in the part of Agathe, in *Der Freischütz*, in 1838, and by 1841, when she started for Paris in order to enlarge her artistic views and to obtain advice upon the subject of her voice, she had already become identified with nearly all the parts in which she afterwards became famous. But her celebrity in Sweden was due in great part to her histrionic ability, and there is comparatively little said about her wonderful vocal art, which was only attained after a year's hard study under Manuel Garcia, who had to remedy many faults that had caused exhaustion in the vocal organs. On the completion of her studies she sang before Meyerbeer, in private, in the Paris Opera-house, and two years afterwards was engaged by him for Berlin, to sing in his *Feldlager in Schlesien*; but the part intended for her was taken by another singer, and her first appearance took place in *Norma*, 15th December 1844. She appeared also in *Euryanthe* and *La Sonnambula*, and while she was at Berlin the English manager, Alfred Bunn, induced her to sign a contract (which she broke) to appear in London in the following season. In December 1845 she appeared at a Gewandhaus concert at Leipzig, and made the acquaintance of Mendelssohn, as well as of Joachim and many other distinguished German musicians. In her second Berlin season she added the parts of Donna Anna (*Don Giovanni*), Julia (*Vestalin*), and Valentine (*Les Huguenots*) to her repertory. She sang in operas or concerts at Aix-la-Chapelle, Hanover, Hamburg, Vienna, Darmstadt, and Munich during the next year, and took up two Donizetti rôles, those of Lucia and "la Figlia del Reggimento," in which she was afterwards famous. At last Lumley, the manager of Her Majesty's Theatre, succeeded in inducing Mlle Lind to visit England, in spite of her dread of the penalties threatened by Bunn on her breach of the contract with him, and she appeared on 4th May 1847, in *Robert le Diable*. Her *début* had been so much discussed that the *favore* she created was a foregone conclusion. Still, it exceeded everything of the kind that had taken place in London or anywhere else, in the genuine enthusiasm the singer made; the sufferings and struggles of her well-dressed admirers, who had to stand for hours to get into the pit, have become historical. She sang in several of her favourite characters, and in that of Susanna in *Figaro*, besides creating the part of Amalia in Verdi's unsuccessful opera, *I Masnadieri*, written for England and performed 22nd July. In the autumn she appeared in operas in Manchester and Liverpool, and in concerts at Brighton, Birmingham, Hull, Edinburgh, Glasgow, Perth, Norwich, Bristol, Bath, and Exeter. At Norwich began her acquaintance with Bishop Stanley, which was said to have caused her final determination to give up the stage as a career. After four more appearances at Berlin, and a short visit to Stockholm, she reappeared in London in the season of 1848, when she sang in *L'Elisire d'Amore* and *I Puritani*, in addition to her older parts. In the same year she organized a memorable performance of *Elijah*, with the receipts of which the Mendelssohn Scholarship was founded, and sang

at a great number of charity and benefit concerts. At the beginning of the season of 1849 she intended to give up operatic singing, but a compromise was effected by which she was to sing the music of six operas, performed without action, at Her Majesty's Theatre; but the first, a concert performance of *Il Flauto Magico*, was so coldly received that she felt bound, for the sake of the manager and the public, to give five more regular representations, and her last stage performance was on the 10th May 1849, in *Robert le Diable*. Her decision was not even revoked when the king of Sweden urged her to reappear in opera at her old home. She paid visits to Germany and Sweden again before her departure for America in 1850. Just before sailing she appeared at Liverpool, for the first time in England, in an oratorio of Handel, singing the soprano music in *The Messiah* with superb art. She remained in America for nearly two years, being for a great part of the time engaged by Barnum, the famous speculator. In Boston, on 5th February 1852, she married Mr Otto Goldschmidt, whom she had met at Lübeck in 1850. For some years after her return to England, her home for the rest of her life, she appeared in oratorios and concerts, and her dramatic instincts were as strongly and perhaps as advantageously displayed in these surroundings as they had been on the stage, for the grandeur of her conceptions in such passages as the "Sanctus" of *Elijah*, the intensity of conviction which she threw into the scene of the widow in the same work, or the religious fervour of "I know that my Redeemer liveth," could not have found a place in opera. In her later years she took an active interest in the Bach Choir, conducted by her husband, and not only sang herself in the chorus, but gave the benefit of her training to the ladies of the society. For some years she was professor of singing at the Royal College of Music, and throughout her life devoted herself to the cause of charity. She died at her cottage, Wynd's Point, Malvern, 2nd November 1887. The supreme position she held so long in the operatic world was due not only to the glory of her ringing voice, and the complete musicianship which distinguished her above all her contemporaries, but also to the naïve simplicity of her acting in her favourite parts, such as Amina, Alice, or Agathe. In these and others she had the precious quality of conviction, and identified herself with the characters she represented with a thoroughness rarer in her day than in ours. Unharmful by the perils of a stage career, and unspoiled by the extraordinary *furor* of the British public, she was a model of rectitude, generosity, and straightforwardness, carrying the last quality into a certain blunt directness of manner that was sometimes rather startling to those who only knew her in her later years.

(J. A. F. M.)

Lindau, Paul (1839—), German author, was born at Magdeburg in 1839. After studying at the Universities of Halle and Berlin, he resided for some time in Paris; on returning to Germany in 1863 he engaged at first in journalism, but gave his attention more specifically to Hellenistic literature. In 1869 he founded *Das Neue Blatt*, in 1871 *Die Gegenwart*, and in 1877 the well-known monthly *Nord und Süd*. His earliest independent productions were some prettily conceived books of travel, *Aus Venetien* (1864) and *Aus Paris* (1865); but it was his critical sketches, notably *Die harmlosen Briefe eines deutschen Kleinstädters* (1870) and *Litterarische Rücksichtslosigkeiten* (1871), written in a light satirical vein, that first brought his name into prominence. His versatile pen also attempted with success various stage plays, which appeared under the title *Theater* in 1873–81. They are distinguished by bright-

ness of dialogue and action, but are not remarkable for originality. As a novelist he has published many charming stories, such as *Im Fieber* (1890), *Herr und Frau Bauer* (ninth edition, 1899), *Helene Jung*, &c.

Linden. See HANOVER.

Lindley, Nathaniel Lindley, BARON (1828—), English judge, eldest son of John Lindley, M.D., F.R.S., (see *Ency. Brit.*, ninth edition, vol. xiv. p. 663), was born at Acton Green, Middlesex, in 1828. He was educated at University College School, and studied for a short time at University College, London, which, however, he left without taking a degree; he then went to France, where he spent nearly a year. In September 1847 he entered as a student at the Middle Temple, where he was called to the bar on the 22nd of November 1850. In 1851 he went to Germany in order to learn German; in 1854 he took chambers in Lincoln's Inn, and commenced practice in the Court of Chancery. In 1855 he published *An Introduction to the Study of Jurisprudence*, consisting of a translation of the general part of Thibaut's *System des Pandekten Rechts*, with copious notes and references to illustrative cases decided in English courts. In 1860 he published in two volumes his *Treatise on the Law of Partnership, including its Application to Joint Stock and other Companies*, and in 1862 a supplement including the Companies Act of 1862. This work has since been developed into two text-books well known to lawyers as *Lindley on Companies* and *Lindley on Partnership*, and has gone through several editions. Having practised for twenty-one years at the junior bar, Mr Lindley became a Queen's Counsel in January 1872, and took his seat in the court presided over by Vice-Chancellor Hall. In 1872 he was elected a bencher of the Middle Temple, of which he was treasurer in 1894. In 1875 Baron Pigott, a much-respected judge of the Court of Exchequer, died, and in order to fill his place Mr Justice Huddleston, better known by his later title of Baron Huddleston, was transferred to the Exchequer from the Court of Common Pleas. Mr Lindley, Q.C., was invited by the Lord Chancellor to fill the place thus vacant, and to become a justice of common pleas, the appointment of a chancery barrister to a common-law court being justified by the fusion of law and equity then shortly to be brought about, in theory at all events, by the Judicature Acts. In the course of the changes made by these statutes Mr Justice Lindley became in the same year (1875) a justice of the Common Pleas Division of the High Court of Justice, and in 1880 of the Queen's Bench Division, distinctions perhaps a little confusing to the lay mind, but marking an important period of transition in the constitution of English courts of justice. In 1881 he was raised to the Court of Appeal and made a privy councillor. In 1897, on the retirement of Lord Esher, Lord Justice Lindley was made Master of the Rolls, and in 1900 he was raised to the House of Lords as a Lord of Appeal in Ordinary with a life peerage and the title of Baron Lindley. Thus Lord Lindley as a puisne judge and Lord Justice of Appeal occupied a seat on the bench for twenty-five years, a slightly shorter period than did Lord Bramwell, whom he succeeded in the Court of Appeal. During this period he was distinguished as a judge gifted with great industry, learning, patience, and courtesy, and with a wide experience of law and equity acquired in a Chancery practice and as a common-law judge. He was the last serjeant-at-law to be appointed, and the last judge to wear the serjeant's coif, or rather the black patch representing it, on the judicial wig. Lord Lindley was made Hon. LL.D. of Edinburgh and Cambridge, and Fellow of the Royal Society. He married in 1858 Sarah Katherine, daughter of Edward John Teale.

Lindley, William (1808–1900), English engineer, was born in London on 7th September 1808, and became a pupil under Mr Francis Giles, whom he assisted in designing the Newcastle and Carlisle and the London and Southampton railways. Leaving England about 1837, he was engaged for a time in railway work in various parts of the Continent, and then returned, as engineer-in-chief to the Hamburg–Bergedorf railway, to Hamburg, near which city he had received his early education, and to which he was destined to stand in much the same relation as Haussmann to Paris. His first achievement was to drain the Hammerbrook marshes, and so add some 1400 acres to the available area of the city. His real opportunity, however, came with the great fire which broke out on 5th May 1842 and burned for three days. He was entrusted with the direction of the operations to check its spread, and the strong measures he adopted, including the blowing-up of the town hall, brought his life into danger with the mob, who professed to see in him an English agent charged with the destruction of the port of Hamburg. After the extinction of the fire he was appointed consulting engineer to the Senate and Town Council, to the Water Board, and to the Board of Works, and thus came to have an important share in the rebuilding of the city in its present form. He began with the construction of a complete sewerage system on principles which did not escape criticism at the time, but which experience showed to be good. Between 1844 and 1848 water-works were established from his designs, the intake from the Elbe being at Rothenburgsort. Subsidence tanks were used for clarification, but in 1853, when he designed large extensions, he urged the substitution of sand-filtration, which, however, was not adopted until the cholera epidemic of 1892–1893 had shown the folly of the opposition directed against it. In 1846 he erected the Hamburg gas-works; public baths and wash-houses were built, and large extensions to the port executed according to his plans in 1854, and he supervised the construction of the Altona gas and water works in 1855. Among other services he rendered to the city may be mentioned the trigonometrical survey executed between 1848 and 1860, and the conduct of the negotiations which in 1852 resulted in the sale of the “Steelyard” on the banks of the Thames belonging to it jointly with the two other Hanseatic towns, Bremen and Lübeck; the site of this wharf is now occupied by Cannon Street station. In 1860 he left Hamburg, and during the remaining nineteen years of his professional practice he was responsible for many engineering works in various Continental cities, among them being Frankfurt-on-the-Main, Warsaw, Pesth, Düsseldorf, Galatz, and Basel. In the first-named of these he constructed sewerage works on the same principles as those he followed in Hamburg, and the system was widely imitated not only in Europe, but also in America. In the course of his life he was also consulted in regard to water-works at Berlin, Kiel, Stralsund, Stettin, and Leipzig; he advised the New River Company of London on the adoption of the constant supply system in 1851; and he was commissioned by the British Government to carry out various works in Heligoland, including the big retaining wall “Am Falm.” He died at Blackheath, London, on 22nd May 1900. (H. M. R.)

Lindo, Mark Prager (1819–1879), Dutch prose writer, of English-Jewish descent, was born in London, 18th September 1819. He went to Holland when only nineteen years of age, and his whole literary career was passed there, although at first he had no intention of settling in the Low Countries. Yet, when once established there as a private teacher of the English language, he soon made up his mind to remain, and in 1842 passed

his examination at Arnhem, qualifying him as a professor of English in Holland, subsequently becoming a teacher of the English language and literature at the gymnasium in that town. In 1853 he was appointed in a similar capacity at the Royal Military Academy in Breda. Meanwhile Lindo had obtained a thorough grasp of the Dutch language, partly during his student years at Utrecht University, where in 1854 he gained the degree of doctor of literature. His proficiency in the two languages led him to translate into Dutch several of the works of then popular English authors, like Dickens, Thackeray, and others, and afterwards also of Fielding, Sterne, and Walter Scott. Some of Lindo’s translations bore the imprint of hasty and careless work, and all were very unequal in quality. His name is much more likely to endure as the writer of humorous original sketches and novelettes in Dutch, which he published under the pseudonym of De Oude Herr Smits (“Old Mr Smits”). Among the most popular are: *Brieven en Ontboezemingen* (“Letters and Confessions,” 1853, with three “Continuations”); *Familie van Ons* (“Family of Ours,” 1855); *Bekentnissen eener Jonge Dame* (“Confessions of a Young Lady,” 1858); *Uittreksels uit het Dagboek van Wijlen den Heer Janus Snor* (“Extracts from the Diary of the late Mr Janus Snor,” 1865); *Typen* (“Types,” 1871); and, particularly, *Afdrukken van Indrukken* (“Impressions from Impressions,” 1854, reprinted many times). The last-named was written in collaboration with Lodewyk Mulder, who contributed some of its drollest whimsicalities of Dutch life and character, which, for that reason, are almost untranslatable. Lodewyk Mulder and Lindo also founded together, and carried on, for a considerable time alone, the *Nederlandsche Spectator* (“The Dutch Spectator”), a literary weekly, still published at The Hague, which bears little resemblance to its English prototype, and which perhaps reached its greatest popularity and influence when Vosmaer contributed to it a brilliant weekly letter under the fanciful title of *Vlugmaren* (“Swifts”). Lindo’s serious original Dutch writings he published under his own name, the principal one being *De Opkomst en Ontwikkeling van het Engelsche Volk* (“The Rise and Development of the British People,” 2 vols. 1868–1874)—a valuable history. His friend Lodewyk Mulder published in the years 1877–1879 a collected edition of Lindo’s writings in five volumes, and there has since been a popular reissue. Lindo was appointed an inspector of primary schools in the province of South Holland in 1865, a post he held until his death at The Hague on 9th March 1879. (H. T.)

Lindsay, a town and port of entry of Ontario, Canada, and capital of Victoria county, situated on the Scugog river, 57 miles north-east of Toronto by rail, at the junction of the Port Hope and Haliburton branches and the Midland division of the Grand Trunk railway. It has steamboat communication, by way of the Trent canal, with Lake Scugog, and ports on the Trent system between Coboconk and Lakefield. It contains saw and grist mills, agricultural implement and carriage works, and tanneries. Population (1881), 5080; (1891), 6081; (1901), 7003.

Linea, or LA LINEA DE LA CONCEPCION, a town of Spain, in the province and diocese of Cadiz, lying between Gibraltar and San Roque. It is a town of comparatively modern date, and was formerly looked upon as a suburb of San Roque. It is now, however, a distinct frontier post, and headquarters of the Spanish commandant of the lines of Gibraltar. All the buildings are modern and offer nothing artistic. There are barracks, casinos, a theatre, and a bull-ring, much frequented by the inhabitants and garrison of Gibraltar. It has some trade in cereals,

fruit and vegetables. Population (1887), 13,862; (1897), 20,294.

Lingah. See BANDER LINGAH.

Lingayen, a town in the southern extremity of the Gulf of Lingayen, on the west coast of Luzon, Philippine Islands, the capital of the province of Pangasinan. It is a favourite resort during the hot season, on account of its coolness and healthfulness. It has good Government buildings, and a fine church and plaza. The rich agricultural lands in its vicinity produce rice, indigo, Indian corn, sugar-cane, and cotton, and alcohol is made from the juice of the nipa palm, which grows abundantly in the neighbouring swamps. The principal language is Pangasinan; Ilocano is also spoken. Population, 19,000.

Lingen, a town of Prussia, province of Hanover, on the Ems Canal, 43 miles north-north-west of Münster by rail. It was from 1685 to 1819 the seat of a university, and has now iron foundries, machinery factories, railway workshops, and a (female) prison. Population (1900), 7048.

Linköping, a town of the province of Östergötland, Sweden, 142 miles south-west from Stockholm on the railway to Malmö, and 29 miles west-south-west from Norrköping. The cathedral was restored in 1871-82, and in 1885 the Östergötland Museum, with the Dahlgren collection of pictures was opened. At Stångåbro (Stångå Bridge), close by, an obelisk was put up in 1898 to commemorate the important battle of Stångåbro (1598). A circle of stones, in the Iron Market of Linköping, marks the spot where Sigismund's adherents were beheaded in 1600. The town has manufactures of tobacco, cloth, and hosiery. Population (1880), 8752; (1890), 12,649; (1900), 14,552.

Linlithgow, a royal and parliamentary burgh (Falkirk group) and the county town of Linlithgowshire, Scotland, 16 miles by rail west of Edinburgh. Shoemaking and currying and tanning are the staple industries. The ancient parish church has been restored. A Roman Catholic chapel and a jubilee commemoration town hall have been erected. Population (1881), 3913; (1891), 4155; (1901), 4279.

Linlithgowshire, or WEST LOTHIAN, a midland county of Scotland, bounded on the N. by the Firth of Forth, on the S.E. by Midlothian, on the S.W. by Lanarkshire, and on the N.W. by Stirlingshire.

Area and Population.—In 1891 a small part of the parish of Dalmeny in Linlithgow was transferred to the parish of Cramond in Midlothian. The area of the county is 77,310 acres, or about 120 square miles. The population was in 1881, 43,510; in 1891, 52,808; in 1901, 65,699, of whom 35,212 were males and 30,487 females, the males outnumbering the females, as they have done at every census since 1831 in this county. Taking the land area only (76,807 acres or 120·0 square miles), the number of persons to the square mile in 1891 was 440, and the number of acres to the person 1·4. In the registration county the population increased between 1881 and 1891 by 21·4 per cent. Between 1881 and 1891 the excess of births over deaths was 10,417, and the increase of the resident population 9443. The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899:—

Year.	Deaths.	Marriages.	Births.	Per cent. of Illegitimate.
1880	838	293	1741	7·5
1890	951	399	2058	6·95
1899	1022	309	2243	4·8

The following table gives the birth-rate, death-rate, and marriage-rate per 1000 of the population for a series of years:—

	1880.	1881-90.	1890.	1891-98.	1899.
Birth-rate . . .	39·75	40·09	39·07	37·87	35·82
Death-rate . . .	19·13	18·71	18·05	16·82	16·32
Marriage-rate . .	6·69	6·85	7·57	6·63	6·37

In 1891 there were 486 Gaelic-speaking persons in the county, and 192 foreigners. Valuation in 1889-90 £292,108; 1899-1900, £355,123.

Administration.—The county returns a member to Parliament. Linlithgow, the county town, and Queensferry (881) are royal burghs, and belong respectively to Falkirk and Stirling groups of parliamentary burghs. Bo'ness (9100) and Bathgate (6786) are police burghs, and Broxburn (6270) is an important manufacturing centre. There are eleven civil parishes, and there is a combination poorhouse at Linlithgow. The number of paupers and dependants in September 1899 was 1267. Linlithgow is part of the sheriffdom of the Lothians and Peebles, and there is a resident sheriff-substitute, who sits at Linlithgow and Bathgate.

Education.—Thirteen school boards manage 33 schools, which had an average attendance of 8952 in 1898-99; and 8 voluntary schools (4 Roman Catholic) had 1879. There are academies at Linlithgow, Bathgate, and Bo'ness, and 14 other schools earned grants in 1898 for giving higher education. The County Secondary Education Committee receives the bulk of the "residue" grant from the local authorities, and subsidizes with it elementary technical classes (cooking, laundry, and dairy) and science and art and technological classes, furnishing equipment for such classes.

Agriculture.—In 1898, 76 per cent. of the area was under cultivation. The acreage under wood was 5206 in 1895. The farming is predominantly arable, and permanent pasture has for some years almost ceased to increase. Oats are the principal crop; the barley acreage is less than a third of the oat acreage, and the wheat acreage is half the barley. Of the 518 holdings in 1895 the average size was 114 acres. The percentage under 5 acres was 12·93; between 5 and 50 acres, 23·94; and over 50 acres, 63·13. The number of farms between 50 and 100 acres was 87; between 100 and 300, 210; between 300 and 500, 25; and there were 5 over 500. The following table gives the principal acreages at intervals of five years from 1880:—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	59,253	18,032	6857	12,850	21,163	333
1885	59,253	16,107	6216	16,664	20,051	215
1890	59,264	14,342	5838	20,086	18,678	299
1895	59,090	15,078	6248	13,792	23,824	116
1899	58,699	14,860	6152	15,054	22,456	150

The following table gives particulars of the live stock during the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or Calf.	Sheep.	Pigs.
1880	2161	10,957	3687	19,585	1675
1885	2064	12,317	4370	19,647	1580
1890	2144	12,644	4540	30,395	1547
1895	2282	11,918	4572	25,173	2085
1899	2123	12,239	4936	26,476	1996

At the census of 1891, 1623 males and 353 females were returned as being engaged in agriculture.

Industries and Trade.—The working of coal, oil-shale, iron-stone, fire-clay, limestone, and sandstone gives employment, directly or indirectly, to at least half the population. In 1891, 13,775 males and 1562 females were connected with industrial pursuits, and of these 7975 men and 269 women were engaged in industries connected with minerals. The following table shows the output of minerals for 1890 and 1899:—

Year.	Oil Shale.		Coal.		Ironstone.		Sandstone.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	1,218,506	...	782,645	£264,142	76,161	£94,272
1899	1,499,378	£374,844	948,748	£355,780	45,298	£16,987	90,685	£21,489

There were also obtained in 1899, 59,602 tons of fire-clay, valued at £5401 (as compared with 540 tons in 1885). There are oil works at Dalmeny, Broxburn, Philipstoun, Winchburgh, Uphall, Bathgate, and Armadale, blast furnaces near Bo'ness, iron foundries, and steel rolling mills. Fishing is prosecuted on a small scale at Queensferry. The exports are noticed under Bo'ness, the principal port. The total addition to the railway mileage during the last quarter of the 19th century was 15½ miles, three branches of that combined length on the North British system having been opened in 1890.

Linton, Eliza Lynn (1822–1898), English novelist, daughter of the Rev. J. Lynn, vicar of Crosthwaite, in Cumberland, was born at Keswick, 10th February 1822. She early manifested independence of character, and in great measure educated herself from the stores of her father's library. Coming up to London about 1845 with a large stock of miscellaneous erudition, she turned this to account in her first novels, *Azeth the Egyptian* and *Amymone*, a romance of the days of Pericles. Her next story, *Realities*, a tale of modern life (1850), was not successful, and for several years she seemed to have abandoned fiction. When, in 1865, she reappeared with *Grasp your Nettle*, it was as an expert in a new style of novel-writing—stirring, fluent, ably-constructed stories, retaining the attention throughout, but affording little to reflect upon or to remember. Measured by their immediate success, they gave her an honourable position among the writers of her day, and secure of an audience, she continued to write with vigour nearly until her death. *Lizzie Lorton of Greyrigg* (1866), *Patricia Kemball* (1874), *The Atonement of Leam Dundas* (1877) are among the best examples of this more mechanical side of her talent, to which there were notable exceptions in *Joshua Davidson* (1872), a bold but not irreverent adaptation of the story of the Carpenter of Nazareth to that of the French Commune; and *Christopher Kirkland*, a veiled autobiography (1885). Mrs. Linton was even more thoroughly at home in journalism than in fiction; her articles on the "Girl of the Period" in the *Saturday Review* produced a great sensation, and she was long an influential contributor to the *St James's Gazette*, the *Daily News*, and other leading newspapers. Many of her detached essays have been collected. In 1858 she married W. J. Linton, the engraver, but the union was soon terminated by mutual consent; she nevertheless brought up one of Mr Linton's daughters by a former marriage. A few years before her death she retired to Malvern, where she died on 14th July 1898. Her life has been written by Mr G. S. Layard. (R. G.)

Linton, William James (1812–1897), English wood-engraver, republican, and author, was born in London in 1812. He was educated at Stratford, and in his sixteenth year was apprenticed to the wood-engraver G. W. Bonner. His earliest known work is to be found in Martin and Westall's *Pictorial Illustrations of the Bible* (1833). Henceforth his talent received ample recognition, and he rapidly rose to a place amongst the foremost wood-engravers of the time. After working as a journeyman engraver with two or three firms, losing his money over a cheap political library called the "National," and writing a life of Thomas Paine, he went into partnership (1842) with John Orrin Smith. The firm was immediately employed on the *Illustrated London News*, just then projected. The following year Orrin Smith died, and Linton, who had married a sister of Thomas Wade, editor of *Bell's Weekly Messenger*, found himself in sole charge of a business upon which two families were dependent. For years past he had concerned himself with the social and political problems of the time, and was now actively engaged in the republican propaganda. In 1844 he took a prominent part in exposing the violation by the

English post-office of Mazzini's correspondence. This led to a friendship with the Italian revolutionist, and he threw himself with ardour into European politics. He carried the first congratulatory address of English workmen to the French Provisional Government in 1848. He edited a twopenny weekly paper, *The Cause of the People*, published in the Isle of Man, and he wrote political verses for the Dublin *Nation*, signed "Spartacus." He helped to found the "International League" of patriots, and in 1850, with G. H. Lewes and Thornton Hunt, started *The Leader*, an organ which, however, did not satisfy his advanced republicanism, and from which he soon withdrew. The same year he wrote a series of articles propounding the views of Mazzini in *The Red Republican*. In 1852 he took up his residence at Brantwood, which he afterwards sold to John Ruskin, and from there issued *The English Republic*, first in the form of weekly tracts and afterwards as a monthly magazine—"a useful exponent of republican principles, a faithful record of republican progress throughout the world; an organ of propagandism and a medium of communication for the active republicans in England." Most of the paper, which never paid its way and was abandoned in 1855, was written by himself. In 1852 he also printed for private circulation an anonymous volume of poems entitled *The Plaint of Freedom*. After the failure of his paper he returned to his proper work of wood-engraving, which had been largely abandoned for political agitation. In 1857 his wife died, and in the following year he married Eliza Lynn (afterwards known as Mrs Lynn Linton) and returned to London. In 1864 he retired to Brantwood, his wife remaining in London. In 1867, pressed by financial difficulties, he determined to try his fortune in America, and finally separated from his wife, with whom, however, he always corresponded affectionately. With his children he settled at Appledore, New Haven, Connecticut, where he set up a printing-press. Here he wrote *Practical Hints on Wood-Engraving*, 1879; *James Watson, a Memoir of Chartist Times*, 1879; *A History of Wood-Engraving in America*, 1882; *Wood-Engraving, a Manual of Instruction*, 1884; *The Masters of Wood-Engraving*, for which he made two journeys to England, 1890; *The Life of Whittier*, 1893; and *Memories*, an autobiography, 1895. He died at New Haven on 29th December 1897, aged eighty-five. Linton was a singularly gifted man, who, in the words of his wife, if he had not bitten the Dead Sea apple of impracticable politics, would have risen higher in the world of both art and letters. As an engraver on wood he reached the highest point of execution in his own line. He carried on the tradition of Bewick, fought for intelligent as against merely manipulative excellence in the use of the graver, and championed the use of the "white line" as well as of the black, believing with Ruskin that the former was the truer and more telling basis of aesthetic expression in the wood-block printed upon paper.

See also W. J. LINTON, *Memories*; F. G. KITTON, article on "Linton" in *English Illustrated Magazine* (April 1891); G. S. LAYARD, *Life of Mrs Lynn Linton* (1901). (G. S. L.)

Linz, the capital of Upper Austria, on the right bank of the Danube, 20 miles north-north-west of Steyr. The population in 1890 was 47,685; in 1900, including Urfahr on the left bank of the Danube, 58,788, almost exclusively Catholic and German (estimated to have 1 per cent. Czech, 3 per cent. Protestant, and 1 per cent. Jewish). It has a garrison of 3502 men, composed of four battalions of infantry and an artillery regiment. Linz is now fairly provided with educational institutions, while its transit trade and industry have grown with the development of navigation on the river and its extended railway communications. In addition to brewing,

boat-building, &c., it has a number of large printing establishments, machine factories, foundries, and other metal works, and cloth factories, and manufactures matches, leather, vinegar, liqueurs, and mineral waters.

Lipa, a town in the extreme south-eastern portion of the province of Batangas, Luzon, Philippine Islands, known for its cool and healthful climate. It is the centre of an extremely fertile agricultural region, which produces sugar, Indian corn, cacao, tobacco, and indigo. There were formerly extensive coffee plantations in its vicinity, but they were completely destroyed in 1889–90 by an insect pest. The language is Tagalog. Population, 40,000.

Lippa, a market town in the Hungarian county of Temes, on the Maros, 22 miles east-south-east of Arad. Its trade, once very considerable, especially in salt and wood, has decayed, but its cattle fairs and its manufacture of pottery are still famous. It has several important educational institutions. Opposite lies the village of Maria-Radna, with a double-towered monastery of the Franciscans, dating from 1761, which is visited thrice a year by a great number of pilgrims from all parts of the country. Population (1901), 7427.

Lippe, a principality of Germany, lying mainly between Westphalia and Hanover. Out of a total of 25,059 farms in 1895, no less than 16,109 were under 2½ acres each, 7327 between 2½ and 25 acres, 1586 between 25 and 250 acres, and only 37 exceeded 250 acres. Potatoes, beetroot (for sugar), hay, rye, oats, wheat, and barley are the principal crops. In 1900 the live stock consisted of 38,362 cattle, 86,513 pigs, 16,085 sheep, and 9477 horses. In 1900 the population was 139,238, giving on an area of 469 square miles a density of 296 persons to the square mile; of this total, 67,113 were males and 72,125 were females. Except for 4332 Roman Catholics and 989 Jews, the people were in 1895 all Protestants. In 1885 the population was 123,212. For the year 1900–01 the state revenue was estimated at £69,760 and the expenditure at £70,400. The public debt amounted in 1900 to £58,400, and the contribution to the imperial exchequer to £67,915.

Lippstadt, a town of Prussia, province of Westphalia, on the river Lippe, and 20 miles by rail west by south of Paderborn. St Mary's church is a large building in the Transitional style, built in 1189 and 1290. Lippstadt itself dates from 1168. It carries on distilling, and manufacture of cigars, gingerbread, sausages, &c. Population (1885), 10,504; (1900), 12,534.

L I Q U I D G A S E S.

THIS article will be mainly confined to the discussion of the properties of liquid atmospheric air and the so-called "permanent" gases—oxygen, nitrogen, and hydrogen—which are contained in it, the last, however, being present in very minute quantities. In the earlier volumes of this Encyclopædia it was stated (9th ed., vol. xii. p. 433) that all these permanent gases had been reduced to the liquid state by Cailletet and Pictet, working independently, and that the latter even succeeded in solidifying hydrogen, the least condensible of all the substances then isolated by the chemist. These statements, at the time they were made, embodied what was generally accepted as a correct account of the facts. But in the course of the next decade widened knowledge rendered it evident that the achievements of those investigators were not of so absolute and definite a character as had at first been supposed, and it became clear that if they were to be accepted at all it must be with certain important qualifications. In the first place, it was noted that what these experimenters obtained was at the best a "dynamic," not a "static" liquid; that is, the gas was reduced to a form which bore the same relation to a true liquid that the partially condensed steam seen issuing from the funnel of a locomotive does to water standing in a tumbler. Thus Cailletet in 1877 compressed about 100 cc. of oxygen to about 200 atmospheres, at the same time cooling it to -29° C., and on suddenly taking off the pressure he saw momentarily in the interior of the tube into which the gas was expanded a mist ("brouillard"), from which he inferred the "presence of a vapour very near its point of liquefaction." A few days later he repeated the experiment with hydrogen, using a pressure of nearly 300 atmospheres, and observed in his tube a fine mist which vanished almost instantaneously. We know now this mist could not be liquid hydrogen drops, because the cooling produced by the adiabatic expansions would only give a theoretical temperature of 44° absolute, which is certainly above the true critical point of hydrogen. But neither of these gases, any more than nitrogen (of which, however, he claimed to obtain "droplets of appreciable size"), was he able to get in the

form of a true stable liquid. Pictet, again, on opening the tap of a vessel in which hydrogen was contained at a pressure of 650 atmospheres and a temperature of -140° C., saw issuing from the orifice an opaque jet, which he assumed to consist of hydrogen in the liquid form, or in the liquid and solid forms mixed, but he was not more successful than Cailletet in collecting any of the liquid. In the second place, some critics deny Cailletet and Pictet the credit of even this approximate liquefaction, and hold the opinion that the mist of the one and the liquid of the other, whatever else they may have been—whether ordinary air or impurities associated with the hydrogen used—were not composed of liquid hydrogen, since the means employed by these experimenters were quite inadequate to reduce the gas to what has more recently been ascertained to be its critical point, above which of course liquefaction is impossible. It need scarcely be added that if the liquefaction of hydrogen be rejected, *a fortiori* Pictet's claim to have effected its solidification falls to the ground.

After Cailletet and Pictet, the next important names in the history of the liquefaction of gases are those of Wroblewski and Olszewski, who for some years worked together at Cracow. In April 1883 the former announced to the French Academy that he had obtained oxygen in a completely liquid state, and (a few days later) that nitrogen at a temperature of -136° C., reduced suddenly from a pressure of 150 atmospheres to one of 50, had been seen as a liquid which showed a true meniscus, but disappeared in a few seconds. But with hydrogen treated in the same way he failed to obtain even the mist reported by Cailletet. At the beginning of 1884 he performed a more satisfactory experiment. Cooling hydrogen in a capillary glass tube to the temperature of liquid oxygen, he expanded it quickly from 100 atmospheres to one, and obtained the appearance of an instantaneous ebullition. Olszewski confirmed this result by expanding from a pressure of 190 atmospheres the gas cooled by liquid oxygen and nitrogen boiling under reduced pressure, and even announced that he saw it running down the walls of the tube as a colourless liquid.

Wroblewski, however, was unable to observe this phenomenon, and Olszewski himself, when seven years later he repeated the experiment in the more favourable conditions afforded by a larger apparatus, was unable to produce again the colourless drops he had previously reported: the phenomenon of the appearance of sudden ebullition indeed lasted longer, but he failed to perceive any meniscus such as would have been a certain indication of the presence of a true liquid. Still, though neither of these investigators succeeded in reaching the goal at which they aimed, their work was of great value in elucidating the conditions of the problem and in perfecting the details of the apparatus employed. Wroblewski in particular devoted the closing years of his life to a most valuable investigation of the isothermals of hydrogen at low temperatures. From the data thus obtained he constructed a van der Waals equation which enabled him to calculate the critical temperature, pressure, and density of hydrogen with very much greater certainty than had previously been possible. Liquid oxygen, liquid nitrogen, and liquid air—the last was first made by Wroblewski in 1885—became something more than mere curiosities of the laboratory, and by the year 1891 were produced in such quantities as to be available for the purposes of scientific research. Still, nothing was added to the general principles upon which the work of Cailletet and Pictet was based, and the “cascade” method, together with adiabatic expansion from high compression (see CONDENSATION OF GASES), remained the only means of procedure at the disposal of experimenters in this branch of physics.

In some quarters a certain amount of doubt appears to have arisen as to the sufficiency of these methods for the liquefaction of hydrogen. Olszewski, for example, in 1895 pointed out that the succession of less and less condensible gases necessary for the cascade method breaks down between nitrogen and hydrogen, and he gave as a reason for hydrogen not having been reduced to the condition of a static liquid the non-existence of a gas intermediate in volatility between those two. By 1894 attempts had been made in the Royal Institution laboratories to manufacture an artificial gas of this nature by adding a small proportion of air to the hydrogen, so as to get a mixture with a critical point of about -200°C . When such a mixture was cooled to that temperature and expanded from a high degree of compression into a vacuum vessel, the result was a white mass of solid air together with a clear liquid of very low density. This was in all probability hydrogen in the true liquid state, but it was not found possible to collect it owing to its extreme volatility. Whether or not this artificial gas would ultimately have enabled liquid hydrogen to be collected in open vessels it is impossible to say, for experiments with it were abandoned in favour of other measures, the employment of which led finally to a more assured success.

Vacuum Vessels.—The problem involved in the liquefaction of hydrogen was in reality a double one. In the first place, the gas had to be cooled to such a temperature that the change to the liquid state was rendered possible. In the second, means had to be discovered for protecting it, when so cooled, from the influx of external heat, and since the rate at which heat is transferred from one body to another increases very rapidly with the difference between their temperatures, the question of efficient heat insulation became at once more difficult and more urgent in proportion to the degree of cold attained. The second part of the problem was in fact solved first. Of course packing with non-conducting materials was an obvious expedient when it was not necessary that the contents of the apparatus should be visible to the eye, but in the numerous instances when this was not the case such measures were out of the question. Attempts were made

to secure the desired end by surrounding the vessel that contained the cooled or liquid gas with a succession of other vessels, through which was conducted the vapour given off from the interior one. Such devices involved awkward complications in the arrangement of the apparatus, and besides were not as a rule very efficient, although some workers, *e.g.*, Dr Kamerlingh Onnes, of Leyden, reported some success with their use. In 1892 it occurred to Dewar that the principle of an arrangement he had used nearly twenty years before for some calorimetric experiments on the physical constants of hydrogenium, which was a natural deduction from the work of Dulong and Petit on radiation, might be employed with advantage as well to protect cold substances from heat as hot ones from cold. He therefore tried the effect of surrounding his liquefied gas

FIG. 1.—Vacuum or “Dewar” Vessels.

with a highly exhausted space. The result was entirely successful. Experiment showed that liquid air contained in a glass vessel with two walls, the space between which was a high vacuum, evaporated at only one-fifth the rate it did when in an ordinary vessel surrounded with air at atmospheric pressure, the convective transference of heat by means of the gas particles being enormously reduced owing to the vacuum. Fig. 1 shows two of these vessels; other forms may be seen in the Plate illustrating the lecture-table at the Royal Institution. But in addition these vessels lent themselves to an arrangement by which radiant heat could also be cut off, and it was found that when the inner wall was coated with a bright deposit of silver, the influx of heat was diminished to one-sixth of the amount existing without the metallic coating. The total effect, therefore, of the high vacuum and silvering is to reduce the in-going heat to one-thirtieth part. In making such vessels a mercurial vacuum has been found very satisfactory. The vessel in which the vacuum is to be produced is provided with a small subsidiary vessel joined by a narrow tube with the main vessel, and connected with a powerful air-pump. A quantity of mercury

having been placed in it, it is heated in an oil- or air-bath to about 200° C., so as to volatilize the mercury, the vapour of which is removed by the pump. After the process has gone on for some time, the pipe leading to the pump is sealed off, the vessel immediately removed from the bath, and the small subsidiary part immersed in some cooling agent such as solid carbonic acid or liquid air, whereby the mercury vapour is condensed in the small vessel and a vacuum of enormous tenuity left in the large one. The final step is to seal off the tube connecting the two. In this way a vacuum may be produced having a vapour pressure of about the hundred-millionth of an atmosphere at 0° C. If, however, some liquid mercury be left in the space in which the vacuum is produced, and the containing part of the vessel be filled with liquid air, the bright mirror of mercury which is deposited on the inside wall of the bulb is still more effective than silver in protecting the chamber from the influx of heat, owing to the high refractive index, which involves great reflecting power, and the bad heat-conducting powers of mercury.

Thermal Transparency at Low Temperatures.—The proposition, once enunciated by Pictet, that at low temperatures all substances have practically the same thermal transparency, and are equally ineffective as non-conductors of heat, is based on erroneous observations. It is true that if the space between the two walls of a double-walled vessel is packed with substances like carbon, magnesia, or silica, liquid air placed in the interior will boil off even more quickly than it will when the space merely contains air at atmospheric pressure; but in such cases it is not so much the carbon, &c., that bring about the transference of heat, as the air contained in their interstices. If this air be pumped out such substances are seen to exert a very considerable influence in stopping the influx of heat, and a vacuum vessel which has the space between its two walls filled with a non-conducting material of this kind preserves a liquid gas even better than one in which that space is simply exhausted of air. In experiments on this point double-walled glass tubes, as nearly identical in shape and size as possible, were mounted in sets of three on a common stem which communicated with an air-pump, so that the degree of exhaustion in each was equal. In two of each three the space between the double walls was filled with the powdered material it was desired to test, the third being left empty and used as the standard. The time required for a certain quantity of liquid air to evaporate from the interior of this empty bulb being called 1, in each of the eight sets of triple tubes, the times required for the same quantity to boil off from the other pairs of tubes were as follows:—

{ Charcoal 5	{ Lampblack 5
{ Magnesia 2	{ Silica 4
{ Graphite 1·3	{ Lampblack 4
{ Alumina 3·3	{ Lycopodium 2·5
{ Calcium carbonate 2·5	{ Barium carbonate 1·3
{ Calcium fluoride 1·25	{ Calcium phosphate 2·7
{ Phosphorus (amorphous) 1	{ Lead oxide 2
{ Mercuric iodide 1·5	{ Bismuth oxide 6

Other experiments of the same kind made—(a) with similar vacuum vessels, but with the powders replaced by metallic and other septa; and (b) with vacuum vessels having their walls silvered, yielded the following results:—

{ (a) Vacuum space empty 1	{ Vacuum space empty 1
{ Three turns silver paper, bright surface inside 4	{ Three turns black paper, black outside 3
{ Three turns silver paper, bright surface outside 4	{ Three turns black paper, black inside 3
{ Vacuum space empty 1	{ Vacuum space empty 1
{ Three turns gold paper, gold outside 4	{ Three turns, not touching, of sheet lead 4
{ Some pieces of gold-leaf put in so as to make contact between walls of vacuum-tube 0·3	{ Three turns, not touching, of sheet aluminium 4
{ (b) Vacuum space empty, silvered on inside surfaces 1	{ Empty silvered vacuum 1
{ Silica in silvered vacuum space 1·1	{ Charcoal in silvered vacuum 1·25

It appears from these experiments that silica, charcoal, lamp-black, and oxide of bismuth all increase the heat insulations to four, five, and six times that of the empty vacuum space. As the chief communication of heat through an exhausted space is by molecular bombardment, the fine powders must shorten the free path of the gaseous molecules, and the slow conduction of heat through the porous mass must make the conveyance of heat-energy more difficult than when the gas molecules can impinge upon the relatively hot outer glass surface, and then directly on the cold one without interruption. (See *Proc. Roy. Inst.*, vol. xv. pp. 821–826.)

Density of Solids and Coefficients of Expansion at Low Temperatures.—The facility with which liquid gases, like oxygen or nitrogen, can be guarded from evaporation by the proper use of vacuum vessels (now called Dewar vessels), naturally suggests that the specific gravities of solid bodies can be got by direct weighing when immersed in such fluids. If the density of the liquid gas is accurately known, then the loss of weight by fluid displacement gives the specific gravity compared to water. The metals and alloys, or substances that can be got in large crystals, are the easiest to manipulate. If the body is only to be had in small crystals, then it must be compressed under strong hydraulic pressure into coherent blocks weighing about 40 to 50 grammes. Such an amount of material gives a very accurate density of the body about the boiling point of air, and a similar density taken in a suitable liquid at the ordinary temperature enables the mean coefficient of expansion between +15° C. and –185° C. to be determined. One of the most interesting results is that the density of ice at the boiling point of air is not more than 0·93, the mean coefficient of expansion being therefore 0·000081. As the value of the same coefficient between 0° C. and –27° C. is 0·000155, it is clear the rate of contraction is diminished to about one-half of what it was above the melting point of the ice. This suggests that by no possible cooling at our command is it likely we could ever make ice as dense as water at 0° C., far less 4° C. In other words, the volume of ice at the zero of temperature would not be the minimum volume of the water molecule, though we have every reason to believe it would be so in the case of the majority of known substances. Another substance of special interest is solid carbonic acid. This body has a density of 1·53 at –78° C. and 1·633 at –185° C., thus giving a mean coefficient of expansion between these temperatures of 0·00057. This value is only about $\frac{1}{3}$ of the coefficient of expansion of the liquid carbonic acid gas just above its melting point, but it is still much greater at the low temperature than that of highly expansive solids like sulphur, which at 40° C. has a value of 0·00019. The following table gives the densities at the temperature of boiling liquid air (–185° C.) and at ordinary temperatures (17° C.), together with the mean coefficient of expansion between those temperatures, in the case of a number of hydrated salts and other substances:—

TABLE I.

¹ The figures within parentheses refer to the number of molecules of water of crystallization.

² –189° to –38°·85 C.

It will be seen from this table that, with the exception of carbonate of soda and chrome alum, the hydrated salts have a coefficient of expansion that does not differ greatly from that of ice at low temperatures. Iodoform is a highly expansive body like iodine, and oxalate of methyl has nearly as great a coefficient as paraffin, which is a very expansive solid, as are naphthalene and oxalic acid. The coefficient of solid mercury is about half that of the liquid metal, while that of sodium is about the value of mercury at ordinary temperatures. Further details on the subject can be found in the *Proc. Roy. Inst.*, 1895, and *Proc. Roy. Soc.*, 1902.

Density of Gases at Low Temperatures.—The ordinary mode of determining the density of gases may be followed, provided that the glass flask, with its carefully ground stop-cock sealed on, can stand an internal pressure of about five atmospheres, and that all the necessary corrections for change of volume are made. All that is necessary is to immerse the exhausted flask in boiling oxygen, and then to allow the second gas to enter from a gasometer by opening the stop-cock until the pressure is equalized. The stop-cock being closed, the flask is now taken out of the liquid oxygen and left in the balance-room until its temperature is equalized. It is then weighed against a similar flask used as a counterpoise. Following such a method, it has been found that the weight of 1 litre of oxygen vapour at its boiling point of $90^{\circ}5$ absolute is 4.420 grammes, and therefore the specific volume is 226.25 cc. According to the ordinary gaseous laws, the litre ought to weigh 4.313 grammes, and the specific volume should be 231.82 cc. In other words, the product of pressure and volume at the boiling point is diminished by 2.46 per cent. In a similar way the weight of a litre of nitrogen vapour at the boiling point of oxygen was found to be 3.90, and the inferred value for 78° absolute, or its own boiling point, would be 4.51, giving a specific volume of 221.3.

Regenerative Cooling.—One part of the problem being thus solved and a satisfactory device discovered for warding off heat in such vacuum vessels, it remained to arrange some practically efficient method for reducing hydrogen to a temperature sufficiently low for liquefaction. To gain that end, the idea naturally occurred of using adiabatic expansion, not intermittently, as when gas is allowed to expand suddenly from a high compression, but in a continuous process, and an obvious way of attempting to carry out this condition was to enclose the orifice at which expansion takes place in a tube, so as to obtain a constant stream of cooled gas passing over it. But further consideration of this plan showed that although the gas jet would be cooled near the point of expansion owing to the conversion of a portion of its sensible heat into dynamical energy of the moving gas, yet the heat it thus lost would be restored to it almost immediately by the destruction of this mechanical energy through friction and its consequent reconversion into heat. Thus the net result would be *nil* so far as change of temperature through the performance of external work was concerned. But the conditions in such an arrangement resemble that in the experiments of Thomson and Joule on the thermal changes which occur in a gas when it is forced under pressure through a porous plug or narrow orifice, and those experimenters found, as the former of them had predicted, that a change of temperature does take place, owing to internal work being done by the attraction of the gas molecules. Hence the effective result obtainable in practice by such an attempt at continuous adiabatic expansion as that suggested above is to be measured by the amount of the "Thomson-Joule effect," which depends entirely on the internal, not the external, work done by the gas. To Linde belongs the credit of having first seen the essential importance of this effect in connexion with the liquefaction of gases by adiabatic expansion, and he was, further, the first to construct an industrial plant for the production of liquid air based on the application of this principle.

The change of temperature due to the Thomson-Joule effect varies in amount with different gases, or rather with the temperature at which the operation is conducted. At ordinary temperatures oxygen and carbonic acid are cooled, while hydrogen is slightly heated. But hydrogen also is cooled if before being passed through the nozzle or plug it

is brought into a thermal condition comparable to that of other gases at ordinary temperatures—that is to say, when it is initially cooled to a temperature having the same ratio to its critical point as their temperatures have to their critical points—and similarly the more condensible gases would be heated, and not cooled, by passing through a nozzle or plug if they were employed at a temperature sufficiently above their critical points. Each gas has therefore a point of inversion of the Thomson-Joule effect, and this temperature is, according to the theory of van der Waals, about 6.75 times the critical temperature of the body. Olszewski has determined the inversion-point in the case of hydrogen, and finds it to be $192^{\circ}5$ absolute, the theoretical critical point being thus about $28^{\circ}5$ absolute. The cooling effect obtained is small, being for air about $\frac{1}{4}^{\circ}$ C. per atmosphere difference of pressure at ordinary temperatures. But the decrement of temperature is proportional to the difference of pressure and inversely as the absolute temperature, so that the Thomson-Joule effect increases rapidly by the combined use of a lower temperature and greater difference of gas pressure. By means of the "regenerative" method of working, which was described by Siemens in 1857, developed and extended by Solvay in 1885, and subsequently utilized by numerous experimenters in the construction of low temperature apparatus, a practicable liquid air plant was constructed by Linde.

The gas which has passed the orifice and is therefore cooled is made to flow backwards round the tube that leads to the nozzle; hence that portion of the gas that is just about to pass through the nozzle has some of its heat abstracted, and in consequence on expansion is cooled to a lower temperature than the first portion. In its turn it cools a third portion in the same way, and so the reduction of temperature goes on progressively until ultimately a portion of the gas is liquefied. Apparatus based on this principle has been employed not only by Linde in Germany, but also by Tripler in America and by Hampson and Dewar in England.

The last-named experimenter exhibited in December 1895 a laboratory machine of this kind (Fig. 2), which when supplied with oxygen initially cooled to -79° C., and at a pressure of 100–150 atmospheres, began to yield liquid in about a quarter of an hour after starting. The initial cooling is not necessary, but it has the advantage of reducing the time required for the operation. The efficiency of the Linde process is

Fig. 2.—Laboratory Liquid Air Machine. A, air or oxygen inlet; B, carbon dioxide inlet; C, carbon dioxide valve; D, regenerator coils; E, air or oxygen expansion valve; G, vacuum vessel with liquid air or oxygen; H, carbon dioxide and air outlet; O, air coil; ●, carbon dioxide coil.

small, but it is easily conducted and only requires plenty of cheap power. When we can work turbines or other engines at low temperatures, so as to effect cooling through the performance of external work, then the economy in the production of liquid air and hydrogen will be greatly increased.

This treatment was next extended to hydrogen. For the reason already explained, it would have been futile to experiment with this substance at ordinary temperatures, and therefore as a preliminary it was cooled to the temperature of boiling liquid air, about -190°C . At this temperature it is still $2\frac{1}{2}$ times above its critical temperature, and therefore its liquefaction in these circumstances would be comparable to that of air, taken at $+60^{\circ}\text{C}$., in an apparatus like that just described. Dewar showed in 1896 that hydrogen cooled in this way and expanded in a regenerative coil from a pressure of 200 atmospheres was rapidly reduced in temperature to such an extent that after the apparatus had been working a few minutes the issuing jet was seen to contain liquid,

FIG. 3.—Hydrogen Jet Apparatus. A, cylinder containing compressed hydrogen; B and C, vacuum vessels containing carbonic acid under exhaustion and liquid air respectively; D, regenerating coil in vacuum vessel; F, valve; G, pin-hole nozzle.

which was sufficiently proved to be liquid hydrogen by the fact that it was so cold as to freeze liquid air and oxygen into hard white solids. Though with this apparatus, a diagrammatic representation of which is shown in Fig. 3, it was not found possible at the time to collect the liquid in an open vessel, owing to its low specific gravity and the rapidity of the gas-current, still the general type of the arrangement seemed so promising that in the next two years there was laid down in the laboratories of the Royal Institution a large plant—it weighs 2 tons and contains 3000 feet of pipe—which is designed on precisely the same principles, although its construction is far more elaborate. The one important novelty, without which it is practically impossible to succeed, is the provision of a device to surmount the difficulty of withdrawing the liquefied hydrogen after it has been made. The desideratum is really a means of forming an aperture in the bottom of a vacuum vessel by which the contained liquid may be run out. For this purpose the lower part of the vacuum vessel (D in Fig. 3) containing the jet is modified as shown in Fig. 4; the inner vessel is prolonged

in a fine tube, coiled spirally, which passes through the outer wall of the vacuum vessel, and thus sufficient elasticity is obtained to enable the tube to withstand without fracture the great contraction consequent on the extreme cold to which it is subjected. Such peculiarly shaped vacuum vessels were made by Dewar's directions in Germany, and have subsequently been supplied to and employed by other experimenters.

FIG. 4.—Bottom of Vacuum Vessel.

The external appearance of the liquid hydrogen machine is shown in Fig. 5, while on the Plate may be seen a general view of the liquid hydrogen plant in the Royal Institution. With this apparatus liquid hydrogen was for the first time collected in an open vessel on 10th May 1898. The gas at a pressure of 180 atmospheres was cooled to -205°C . by means of liquid air boiling *in vacuo*, and then passed through the nozzle of the regenerative coil, which was enclosed in vacuum vessels in such a way as to exclude external heat as perfectly as possible. In this way some 20 cc. of the liquid had been collected when the experiment came to a premature end, owing to the nozzle of the apparatus becoming blocked by a dense solid—air-ice resulting from the congelation of the air which was present to a minute extent as an impurity in the hydrogen. This accident exemplifies what is a serious trouble encountered in the production of liquid hydrogen, the extreme difficulty of obtaining the gas in a state of sufficient purity, for the presence of 1 per cent. of foreign matters, such as air or oxygen, which are more condensable than hydrogen, is sufficient to cause complete stoppage, unless the nozzle valve and jet arrangement is of special construction. In subsequent experiments the liquid was obtained in larger quantities—on 13th June 1901 five litres of it were successfully conveyed through the streets of London from the laboratory of the Royal Institution to the rooms of the Royal Society—and it may be said that it is now possible to produce it in any desired amount, subject only to the limitations entailed by expense. Finally, the reduction of hydrogen to a solid state was successfully undertaken in 1899. A portion of the liquid carefully isolated in vacuum-jacketed vessels was suddenly transformed into a white mass resembling frozen foam, when evaporated under an air-pump at a pressure of 30 or 40 mm., and subsequently hydrogen was obtained as a clear transparent ice by immersing a tube containing the liquid in this solid foam.

The following are brief details respecting the more important liquefied gases that have become available for study within recent years. (For argon, neon, krypton, &c., see ARGON.)

Oxygen.—Liquid oxygen is a mobile transparent liquid, possessing a faint blue colour. At atmospheric pressure it boils at $-181^{\circ}\cdot5\text{C}$.; under a reduced pressure of 1 cm. of mercury its temperature falls to -210°C . At the boiling point it has a density of 1.124 according to Olszewski, or of 1.168 according to Wroblewski; Dewar obtained the value 1.1375 as the mean of twenty observations by weighing a number of solid substances in liquid oxygen, noting the apparent relative density of the liquid, and thence calculating its real density, Fizeau's values for the coefficients of expansion of the solids being employed. The capillarity of liquid oxygen is about one-sixth that of water; it is a non-conductor of electricity, and is strongly magnetic. By its own evaporation it cannot be reduced to the solid state, but exposed to the temperature of liquid hydrogen it is frozen into a solid mass, having a pale bluish tint, showing by reflection all the absorption bands of the liquid. It is remarkable that the same absorption bands occur in the compressed gas. Dewar gives the melting-point as 38° absolute. The refractive index of the liquid for the D sodium ray is 1.2236.

Ozone.—This gas is easily liquefied by the use of liquid air. The

LIQUID GASES.

PLANT FOR LIQUEFACTION OF GASES IN LABORATORIES OF ROYAL INSTITUTION, LONDON.

LECTURE TABLE AT ROYAL INSTITUTION, LONDON, ARRANGED FOR LECTURE ON LIQUID GASES.

liquid obtained is intensely blue, and on allowing the temperature to rise, boils and explodes about -120°C . About this temperature it may be dissolved in bisulphide of carbon to a faint blue solution. The liquid ozone seems to be more magnetic than liquid oxygen.

Nitrogen forms a transparent colourless liquid, having a density of 0.800 at its boiling point, which is -195°C . The refractive index for the D line is 1.2053. Evaporated under diminished pressure the liquid becomes solid at a temperature of -215°C ., under a pressure of 64 mm.

Air.—Seeing that the boiling points of nitrogen and oxygen are different, it might be expected that on the liquefaction of atmospheric air the two elements would appear as two separate liquids. Such, however, is not the case; they come down simultaneously as one homogeneous liquid. Prepared on a large scale, liquid air may contain as much as 50 per cent. of oxygen when collected in open vacuum-vessels, but since nitrogen is the more volatile it boils off first, and as the liquid gradually becomes richer in oxygen the temperature at which it boils rises from about -192°C . to about -182°C . At the former temperature it has a density of about 0.910. It is a non-conductor of electricity. Properly protected from external heat, and subjected to high exhaustion, liquid air becomes a stiff transparent jelly-like mass, a magma of solid nitrogen containing liquid oxygen, which may indeed be extracted from it by means of a magnet, or by rapid rotation of the vacuum vessel in imitation of a centrifugal machine. The temperature of this solid under a vacuum of about 14 mm. is -216° . At the still lower temperatures attainable by the aid of liquid hydrogen it becomes a white solid having, like solid oxygen, a faint blue tint. The refractive index of liquid air is 1.2068.

Fluorine, prepared in the free state by Moissan's method of electrolysing a solution of potassium fluoride in anhydrous hydrofluoric acid, was liquefied in the laboratories of the Royal Institution, London, in 1897. Exposed to the temperature of quietly-boiling liquid oxygen, the gas did not change its state, though it lost much of its chemical activity, and ceased to attack glass. But a very small vacuum formed over the oxygen was sufficient to determine liquefaction, a result which was also obtained by cooling the gas to the temperature of freshly-made liquid air boiling at atmospheric pressure. Hence the boiling point is fixed at about -187°C . The liquid is of a clear yellow colour, possessing great mobility. Its density is 1.14, and its capillarity rather less than that of liquid oxygen. The liquid, when examined in a thickness of 1 cm., does not show any absorption bands, and it is not attracted by a magnet. Even when cooled to -210°C ., it shows no sign of becoming solidified.

Hydrogen.—Liquid hydrogen is the lightest liquid known to the chemist, having a density slightly less than 0.07 as compared with

water, and being six times lighter than liquid marsh-gas, which is next in order of lightness. One litre weighs only 70 grammes, and 1 gramme occupies a volume of 14-15 cc. In spite of its extreme lightness, however, it is easily seen, has a well-defined meniscus,

FIG. 5.—Liquid Hydrogen Machine.

and drops well. At its boiling point the liquid is only 55 times denser than the vapour it is giving off, whereas liquid oxygen in similar condition is 258 times denser than its vapour, and nitrogen 177 times. Its atomic volume is about 14.3, that of liquid oxygen being 13.7, and that of liquid nitrogen 16.6, at their respective boiling points. Its latent heat of vaporization about the boiling

point, as deduced from the vapour pressures and helium thermometer temperatures, is about 200 units, and the latent heat of fluidity cannot exceed 16 units, but may be less. Liquid hydrogen has the greatest specific heat of any known body near its melting point, the average being about 6 between the boiling and freezing points. Its surface tension is exceedingly low, about one-fifth that of liquid air at its boiling point, or one-thirty-fifth that of water at ordinary temperatures, and this is the reason that bubbles formed in the liquid are so small as to give it an opalescent appearance during ebullition. The liquid is without colour, and gives no absorption spectrum. Electric sparks taken in the liquid between platinum poles give a spectrum showing the hydrogen lines C. and F. bright on a background of continuous spectrum. Its refractive index at the boiling point has theoretically the value 1.11. It was measured by determining the relative difference of focus for a parallel beam of light sent through a spherical vacuum vessel filled successively with water, liquid oxygen, and liquid hydrogen; the result obtained was 1.12. Liquid hydrogen is a non-conductor of electricity. The precise determination of its boiling point is a matter of some difficulty. The first results obtained from the use of a platinum resistance thermometer gave -238°C ., while a similar thermometer made with an alloy of rhodium-platinum indicated a value 8 degrees lower. Later, a gold thermometer indicated about -249°C ., while with an iron one the result was only -210°C . It was thus evident that electrical resistance thermometers are not to be trusted at these low temperatures, since the laws correlating resistance and temperature are not known for temperatures at and below the boiling point of hydrogen, though they are certainly not the same as those which hold good higher up the thermometric scale. The same remarks apply to the use of thermo-electric junctions at such exceptional temperatures. Recourse was therefore had to a constant-volume hydrogen thermometer, working under reduced pressure, experiments having shown that such a thermometer, filled with either a simple or a compound gas (*e.g.*, oxygen or carbonic acid) at an initial pressure somewhat less than one atmosphere, may be relied upon to determine temperatures down to the respective boiling points of the gases with which they are filled. The result obtained was -252°C . Subsequently various other determinations were carried out in thermometers filled with hydrogen derived from different sources, and also with helium, the average value given by the experiments being -252.5°C . (See "The Boiling Point of Liquid Hydrogen determined by Hydrogen and Helium Gas Thermometers," *Proc. Roy. Soc.*, 7th February 1901.) The critical temperature is about 30° absolute (-243°C .), and the critical pressure about 15 atmospheres. Hydrogen has not only the lowest critical temperature of all the old permanent gases, but it has the lowest critical pressure. Given a sufficiently low temperature, therefore, it is the easiest gas to liquefy so far as pressure is concerned. Solid hydrogen has a temperature about 4 degrees less. By exhaustion under reduced pressure a still lower depth of cold may be attained, and a steady temperature reached less than 16 degrees above the zero of absolute temperature. By the use of high exhaustion, and the most stringent precautions to prevent the influx of heat, a temperature of 13° absolute (-260°C .) may be reached. This is the lowest steady temperature which can be maintained by the evaporation of solid hydrogen. The solid has a density of about 0.09. Solid hydrogen presents no metallic characteristics, such as were predicted for it by Faraday, Dumas, Graham, and other chemists, and neither it nor the liquid is magnetic.

LOW TEMPERATURE RESEARCH.

The subjection of hydrogen completes the experimental proof that all substances can exist in the three states of solid, liquid, and gas, at least so far as concerns those in the hands of the chemist at the beginning of the last decade of the 19th century. But a year or so before hydrogen was obtained in the liquid form, a substance known spectroscopically to exist in the sun from researches carried out by Frankland and Lockyer so far back as 1868, was found by Professor W. Ramsay to exist on this earth, though in excessively small quantities, and experiment has shown helium, as the gas is named, to be much less condensable than hydrogen. It has been expanded from a pressure of 80 to 100 atmospheres at the temperature of solid hydrogen without the least indication of liquefaction being perceived, although in this connexion it must be remembered that its exceedingly low refractivity would render small drops of the liquid forming in the gas near its critical point very difficult to see. It may, however, be said without much doubt that helium has been cooled to 9° or 10° absolute

(264° or 263° below zero centigrade) without sign of liquefaction, and the inference is that its critical point is below 9° absolute. This means that its boiling point is about 5° absolute, or one-fourth that of liquid hydrogen. The hope of liquefying the gas must depend on subjecting it to the same process that has succeeded with hydrogen, but instead of liquid air under exhaustion being used as the primary cooling agent, liquid hydrogen under exhaustion must be employed, and the resulting liquid collected in vacuum vessels immersed in liquid hydrogen. The practical difficulties and cost of the operation will be very great, but, on the other hand, success would mean the command of a liquid probably boiling within 5 degrees of the absolute zero. If a gas of the same series, still unisolated, may exist (as is not impossible), which has an atomic weight half that of helium, this gas, liquefied in turn by the aid of liquid helium, would bring the experimenter still closer to that zero. The following table embodies the results of experiments and of theory based on them. The third column shows the critical temperature of the gas which can be liquefied by continuous expansion through a regenerative cooling apparatus, the operation being started from the initial temperature shown in the second column, while the fourth column gives the temperature of the resulting liquid. It will be seen that by the use of liquid or solid hydrogen as a cooling agent, it should be possible to liquefy a body having a critical temperature of about 6° to 8° on the absolute scale, and a boiling point of about 4° or 5° , while with the aid of liquid helium at an initial temperature of 5° we could liquefy a body having a critical temperature of 2° and a boiling point of 1° .

TABLE II.

Substance.	Initial Temperature. Abs. Degrees.	Critical Temperature. Abs. Degrees.	Boiling Points. Abs. Degrees.
(Low red heat) .	760	304	195 (CO ₂)
(52° C.)	325	130	86 (Air)
Liquid air under exhaustion .	75	30	20 (H)
Liquid hydrogen .	20	8	5 (He ?)
Solid hydrogen .	15	6	4
Liquid helium .	5 ?	2 ?	1 ?

It is to be remarked, however, that even so the physicist would not have attained the absolute zero, and probably he can scarcely ever hope to do so. It is true he would only be a very short distance from it, but it must be remembered that in a thermodynamic sense one degree low down the scale, say at 10° absolute, is equivalent to 30° at the ordinary temperature, and as the experimenter gets to lower and lower temperatures, the difficulties of further advance increase, not in arithmetical but in geometrical progression. Thus the step between the liquefaction of air and that of hydrogen is, thermodynamically and practically, greater than that between the liquefaction of chlorine and that of air, but the number of degrees of temperature that separates the boiling points of the first pair of substances is less than half what it is in the case of the second pair. But the ratio of the absolute boiling points in the first pair of substances is as 1 to 4, whereas in the second pair it is only 1 to 3, and it is this value that expresses the difficulty of the transition.

But though Ultima Thule may continue to mock the physicist's efforts, he will long find ample scope for his energies in the investigation of the properties of matter at the temperatures placed at his command by liquid air and liquid and solid hydrogen. Indeed, great as is the sentimental interest attached to the liquefaction of these refractory gases, the importance of the achievement lies rather in

the fact that it opens out new fields of research and enormously widens the horizon of physical science, enabling the natural philosopher to study the properties and behaviour of matter under entirely novel conditions. This department of inquiry is as yet only in its infancy, but speedy and extensive developments may be looked for, since within recent years several special cryogenic laboratories have been established for the prosecution of such researches, and a liquid air plant is becoming a common adjunct to the equipment of the ordinary chemical laboratory. We propose to indicate briefly the general directions in which these inquiries have so far been carried on, but before doing so will call attention to two important manipulative uses to which liquid gases may be turned.

Production of High Vacua.—The first use of liquid gases is in the production of exceedingly high vacua. If a vessel containing liquid hydrogen be freely exposed to the atmosphere, a rain of snow (solid air) at once sets in; similarly, if one end of a sealed tube containing ordinary air be immersed in the liquid, the same process takes place, but as now there is no new supply available to take the place of the portion that has solidified and fallen to the bottom of the tube, the pressure in the vessel is quickly reduced to something like one-millionth of an atmosphere, and a vacuum is readily formed of such tenuity that the electric discharge can only be made to pass with great difficulty. Liquid air may be used in the same manner if the tube before sealing is filled with some less volatile gas or vapour, such as sulphurous acid, benzol, or water vapour. The last is the most suitable substance to show this rapid production of high vacua by simple cooling. Provided a Geissler tube has platinum poles, and is filled with nothing but vapour of water, it is sufficient to cool a small area of its surface with a sponge containing liquid air to see it pass rapidly through all the phases of striation, and ultimately reach the phosphorescent glow.

Analytic Uses.—The second use of liquid gases is as analytic agents, and for this purpose liquid air is becoming an almost essential laboratory reagent. It is one of the most convenient agents for drying gases and for their purification. If a mixture of gases be subjected to the temperature of liquid oxygen it is obvious that all the constituents that are more condensible than oxygen will be reduced to liquid, while those that are less condensible will either remain as a gaseous residue or be dissolved in the liquid obtained. The bodies present in the latter may be separated by fractional distillation, while the contents of the gaseous residue may be further differentiated by the aid of still lower temperatures, such as are obtainable by liquid hydrogen. An apparatus such as the following can be used to separate both the less and the more volatile gases of the atmosphere, the former being obtained from their solution in liquid air by fractional distillation at low pressure, and separation of the condensible part of the distillate by cooling in liquid hydrogen, while the latter are extracted from the residue of liquid air, after the distillation of the first fraction, by allowing it to evaporate gradually at a temperature rising only very slowly.

In Fig. 6, *A* represents a vacuum-jacketed vessel, containing liquid air; this can be made to boil at reduced pressure and therefore be lowered in temperature by means of an air-pump, which is in communication with the vessel through the pipe *s*. The liquid boiled away is replenished when necessary from the reservoir *C*, *p* being a valve, worked by handle *q*, by which the flow along *r* is

regulated. The vessel *B*, immersed in the liquid air of *A*, communicates with the atmosphere by *a*; hence when the temperature of *A* falls under exhaustion below that of liquid air, the contents of *B* condense, and if the stop-cock *m* is kept open, and *n* shut, air from the outside is continuously sucked in until *B* is full of liquid, which contains in solution the whole of the most volatile gases of the atmosphere which have passed in through *a*. At this stage of the operation *m* is closed and *n* opened, a passage thus being opened along *b* from *A* to the remainder of the apparatus seen on the left side of the figure. Here *E* is a vacuum vessel containing liquid hydrogen, and *d* a three-way cock by which communication can be established either between *b* and *D*, between *D* and *e*, the tube leading to the sparking-tube *g*, or between *D* and *e*. If now *d* is arranged so that there is a free passage from *b* to *D*, and the stop-cock *n* also opened, the gas dissolved in the liquid in *B*, together with some of the most volatile part of that liquid, quickly distils over into *D*, which is at a much lower temperature than *B*, and some of it condenses there in the solid state. When a small fraction of the contents of *B* has thus distilled over, *d* is turned so as to close the passage between *D* and *b* and open that between *D* and *e*, with the result that the gas in *D* is pumped out by the mercury-pump,

FIG. 6.—Apparatus for Fractional Distillation.

shown diagrammatically at *F*, along the tube *e* (which is immersed in the liquid hydrogen in order that any more condensible gas carried along by the current may be frozen out) to the sparking-tube or tubes *g*, where it can be examined spectroscopically. When the apparatus is used to separate the least volatile part of the gases in the atmosphere, the vessel *E* and its contents are omitted, and the tube *b* made to communicate with the pump through a number of sparking-tubes which can be sealed off successively. The nitrogen and oxygen which make up the bulk of the liquid in *B* are allowed to evaporate gradually, the temperature being kept low so as to check the evaporation of gases less volatile than oxygen. When most of the oxygen and nitrogen have thus been removed, the stop-cock *n* is closed, and the tubes partially exhausted by the pump; spectroscopic examination is made of the gases they contain, and repeated from time to time as more gas is allowed to evaporate from *B*. The general sequence of spectra, apart from those of nitrogen, oxygen, and carbon compounds, which are never eliminated by the process of distillation alone, is as follows:—The spectrum of argon first appears, followed by the brightest (green and yellow) rays of krypton. Then the intensity of the argon spectrum wanes and it gives way to that of krypton, until, as Runge observed, when a Leyden jar is in the circuit, the capillary part of the sparking-tube has a magnificent blue colour, while the wide ends are bright pale yellow. Without a jar the tube is nearly white in the middle and yellow about the poles. As distillation proceeds, the temperature of the vessel containing the residue of liquid air being allowed to rise slowly, the brightest (green) rays of xenon begin to appear, and the krypton rays soon die out, being superseded by those of xenon. At this stage the capillary part of the sparking-tube is, with a jar in circuit, a brilliant green, and it remains green, though less brilliant, if the jar is removed.

An improved form of apparatus for the fractionation is represented in Fig. 7. The gases to be separated, that is, the least volatile part of atmospheric air, enter the bulb *B* from a gasholder by the tube *a* with stop-cock *c*. *B*, which is maintained at a low temperature by being immersed in liquid hydrogen, *A*, boiling under reduced pressure, in turn communicates through the tube *b* and stop-cock *d* with a sparking-tube or tubes *f*, and so on

through *e* with a mercurial pump. To use the apparatus, stop-cock *d* is closed and *c* opened, and gas allowed to pass from the gasholder into *B*, where it is condensed in the solid form. Stop-cock *c* then being closed and *d* opened, gas passes into the exhausted tube *f*, where it is examined with the spectroscope. The vessel *D* contains liquid air, in which the tube *e* is immersed in order to condense vapour of mercury which would otherwise pass

FIG. 7.—Apparatus for continuous Spectroscopic Examination.

from the pump into the sparking-tube. The success of the operation of separating all the gases which occur in air and which boil at different temperatures, depends on keeping the temperature of *B* as low as possible, as will be understood from the following consideration:—

The pressure *p*, of a gas *G*, above the same material in the liquid state, at temperature *T*, is given approximately by the formula

$$\log p = A - \frac{B}{T},$$

where *A* and *B* are constants for the same material. For some other gas *G'* the formula will be

$$\log p_1 = A_1 - \frac{B_1}{T},$$

and

$$\log \frac{p}{p_1} = A - A_1 + \frac{B_1 - B}{T}.$$

Now for argon, krypton, and xenon respectively the values of *A* are 6.782, 6.972, and 6.963, and those of *B* are 339, 496.3, and 689.2; so that for these substances and many others *A* - *A*₁ is always a small quantity, while $\frac{B_1 - B}{T}$ is considerable and increases

as *T* diminishes. Hence the ratio of *p* to *p*₁ increases rapidly as *T* diminishes, and by evaporating all the gases from the solid state, and keeping the solid at as low a temperature as possible, the gas that is taken off by the mercurial pump first consists mainly of the substance which has the lowest boiling point, in this case nitrogen, and is succeeded with comparative abruptness by the gas which has the next higher boiling point. Examination of the spectrum in the sparking-tube easily reveals the change from one gas to another, and when that is observed the reservoirs into which the gases are pumped can be changed and the fractions stored separately. Or several sparking-tubes may be arranged so as to form parallel communications between *b* and *e*, and can be successively sealed off at the desired stages of fractionation.

Chemical Action.—By extreme cold chemical action is enormously reduced, though it may not in all cases be entirely abolished even at the lowest temperatures yet attained; one reason for this diminution of activity may doubtless be sought in the fact that in such conditions most substances are solid, that is, in the state least favourable to chemical combination. Thus an electric pile of sodium and carbon ceases to yield a current when immersed in liquid oxygen. Sulphur, iron, and other substances can be made to burn under the surface of liquid oxygen if the combustion is properly established before the sample is immersed, and the same is true of a fragment of diamond. Nitric oxide in the gaseous condition combines instantly with free oxygen, producing the highly-coloured gas, nitric

peroxide, but in the solid condition it may be placed in contact with liquid oxygen without showing any signs of chemical action. If the combination of a portion of the mixture is started by elevation of temperature, then detonation may take place throughout the cooled mass. The stability of endothermic bodies like nitric oxide and ozone at low temperatures requires further investigation. The behaviour of fluorine, which may be regarded as the most active of the elements, is instructive in this respect. As a gas, cooled to -180° C. it loses the power of attacking glass; similarly silicon, borax, carbon, sulphur, and phosphorus at the same temperature do not become incandescent in an atmosphere of the gas. Passed into liquid oxygen, the gas dissolves and imparts a yellowish tint to the liquid; if the oxygen has been exposed to the air for some hours, the fluorine produces a white flocculent precipitate, which if separated by filtering deflagrates with violence as the temperature rises. It appears to be a hydrate of fluorine. As a liquid at -210° fluorine attacks turpentine also cooled to that temperature with explosive force and the evolution of light, while the direction of a jet of hydrogen upon its surface is immediately followed by combination and a flash of flame. A far more severe test of chemical action would be effected by mixing liquid or solid fluorine and liquid hydrogen, but this experiment has yet to be made.

Photographic Action.—The action of light on photographic plates, though greatly diminished at -180° , is far from being in abeyance; an Eastman film, for instance, remains fairly sensitive at -210° . At the still lower temperature of liquid hydrogen the photographic activity is reduced to about half what it is at that of liquid air; in other words, about 10 per cent. of the original sensitivity remains. Experiments carried out with an incandescent lamp, a Röntgen bulb, and the ultra-violet spark from magnesium and cadmium, to discover at what distances from the source of light the plates must be placed in order to receive an equal photographic impression, yielded the following results:—

Source of Light.	Cooled Plate.	Uncooled Plate.	Ratio of Intensities at Balance.
16 C.P. lamp . . .	20 in.	50 in.	1 to 6
Röntgen bulb . . .	10 in.	24½ in.	1 to 6
Ultra-violet spark . . .	22½ in.	90 in.	1 to 16

It appears that the photographic action of both the incandescent lamp and the Röntgen rays is reduced by the temperature of liquid air to 17 per cent. of that exerted at ordinary temperatures, while ultra-violet radiation retains only 6 per cent. It is possible that the greater dissipation of the latter by the photographic film at low temperatures than at ordinary ones is due to its absorption and subsequent emission as a phosphorescent glow, and that if the plate could be developed at a low temperature it would show no effect, the photographic action taking place subsequently through an internal phosphorescence in the film during the time it is heating up. With regard to the transparency of bodies to the Röntgen radiation at low temperatures, small tubes of the same bore, filled with liquid argon and chlorine, potassium, phosphorus, aluminium, silicon, and sulphur, were exposed at the temperature of liquid air (in order to keep the argon and chlorine solid), in front of a photographic plate shielded with a sheet of aluminium, to an X-ray bulb. The sequence of the elements as mentioned represents the order of increasing opacity observed in the shadows. Sodium and liquid oxygen and air, nitrous and nitric oxides, proved much more transparent than chlorine. Tubes of potassium, argon, and liquid chlorine showed no very marked difference of density on the photographic

plates. It appears that argon is relatively more opaque to the Röntgen radiation than either oxygen, nitrogen, or sodium, and is on a level with potassium, chlorine, phosphorus, aluminium, and sulphur. This fact may be regarded as supporting the view that the atomic weight of argon is twice its density relative to hydrogen, since in general the opacity of elements in the solid state increases with the atomic weight.

Phosphorescence.—Phosphorescing sulphides of calcium, which are luminous at ordinary temperatures, and whose emission of light is increased by heating, cease to be luminous if cooled to -80°C . But their light energy is merely rendered latent, not destroyed, by such cold, and they still retain the capacity of taking in light energy at the low temperature, to be evolved again when they are warmed. At the temperature of liquid air many bodies become phosphorescent which do not exhibit the phenomenon at all, or only to a very slight extent, at ordinary temperatures, *e.g.*, ivory, indiarubber, egg-shells, feathers, cotton-wool, paper, milk, gelatine, white of egg, &c. Of definite chemical compounds, the platinocyanides among the inorganic bodies seem to yield the most brilliant effects. Crystals of ammonium platinocyanide, if stimulated by exposure to the ultra-violet radiation of the electric arc, while kept moistened with liquid air, may be seen in the dark to glow faintly so long as they are kept cold, but become exceedingly brilliant when the liquid air evaporates and the temperature rises. Among organic bodies the phenomenon is particularly well marked with the ketonic compounds and others of the same type. The chloro-, bromo-, iodo-, sulpho-, and nitro-compounds show very little effect as a rule. The activity of the alcohols, which is usually considerable, is destroyed by the addition of a little iodine. Coloured salts, &c., are mostly inferior in activity to white ones. When the lower temperature of liquid hydrogen is employed there is a great increase in phosphorescence under light stimulation as compared with that observed with liquid air. The radioactive bodies, like radium, which exhibit self-luminosity in the dark, maintain that luminosity unimpaired when cooled in liquid hydrogen.

Some crystals become for a time self-luminous when placed in liquid hydrogen, because the high electric stimulation due to the cooling causes actual electric discharges between the crystal molecules. This phenomenon is very pronounced with nitrate of uranium and some platinocyanides, and cooling such crystals even to the temperature of liquid air is sufficient to develop marked electrical and luminous effects, which are again observed, when the crystal is taken out of the liquid, during its return to normal temperature. Since both liquid hydrogen and liquid air are good electrical insulators, the fact that electric discharges take place in them proves that the electric potential generated by the cooling must be very high. A crystal of nitrate of uranium indeed gets so highly charged electrically that it refuses to sink in liquid air, although its density is 2.8 times greater, but sticks to the side of the vacuum vessel, and requires for its displacement a distinct pull on the silk thread to which it is attached. Such a crystal quickly removes cloudiness from liquid air by attracting all the suspended particles to its surface, just as a fog is cleared out of air by electrification. It is interesting to observe that neither fused nitrate of uranium nor its solution in absolute alcohol shows any of the remarkable effects of the crystalline state on cooling.

Cohesion.—The physical force known as cohesion is greatly increased by low temperatures. This fact is of much interest in connexion with two conflicting theories of matter. Lord Kelvin's view is that the forces that hold together the ultimate particles of bodies may be accounted

for without assuming any other forces than that of gravitation, or any other law than the Newtonian. An opposite view is that the phenomena of cohesion, chemical union, &c., or the general phenomena of the aggregation of molecules, depend on the molecular vibrations as a physical cause (Tolver Preston, *Physics of the Ether*, p. 64). Hence at the zero of absolute temperature, this vibrating energy being in complete abeyance, the phenomena of cohesion should cease to exist and matter generally be reduced to an incoherent heap of "cosmic dust." This second view receives no support from experiment. Atmospheric air, for instance, frozen at the temperature of liquid hydrogen, is a hard solid, the strength of which gives no hint that with a further cooling of some 20 degrees it would crumble into powder. On the contrary, the lower the scale of temperature is descended, the more powerful become the forces which hold together the particles of matter. A spiral of fusible metal, which at ordinary temperatures cannot support the weight of an ounce without being straightened out, will, when cooled to the temperature of liquid oxygen, and so long as it remains in that cooled condition, support several pounds and vibrate like a steel spring. Similarly a bell of fusible metal at -182°C . gives a distinct metallic ring when struck. Balls of iron, lead, tin, ivory, &c., thus cooled, exhibit an increased rebound when dropped from a height; an indiarubber ball, on the other hand, becomes brittle, and is smashed to atoms by a very moderate fall. The following tables, which give the mean results of a large number of experiments, show the increased breaking stress gained by metals while they are cooled to the temperature of liquid oxygen.

TABLE III.

Breaking stress in pounds of metallic wires 0.098 inch in diameter:—

	+15° C.	-182° C.
Steel (soft)	420	700
Iron	320	670
Copper	200	300
Brass	310	440
German silver	470	600
Gold	255	340
Silver	330	420

TABLE IV.

Breaking stress in pounds of cast metallic test-pieces; diameter of rod -0.2 inch.

	+15° C.	-182° C.
Tin	200	390
Lead	77	170
Zinc	35	26
Mercury	0	31
Bismuth	60	30
Antimony	61	30
Solder	300	645
Fusible metal (Wood)	140	450

In the second series of experiments the test-pieces were 2 inches long and were all cast in the same mould. It will be noticed that in the cases of zinc, bismuth, and antimony the results appear to be abnormal, but it may be pointed out that it is difficult to get uniform castings of crystalline bodies, and it is probable that by cooling such stresses are set up in some set of cleavage planes as to render rupture comparatively easy. In the case of strong steel springs the rigidity modulus does not appear to be greatly affected by cold, for although a number were examined, no measurable differences could be detected in their elongation under repeated additions of the same load. No quantitative experiments have been made on the cohesive properties of the metals at the temperature of boiling hydrogen (-252°), owing to the serious cost that would be involved. A lead wire cooled in liquid hydrogen did not become brittle, as it could be bent backwards and forwards in the liquid.

Electrical Resistivity.—The first experiments on the conductivity of metals at low temperatures appear to have been made by Wroblewski (*Comptes Rendus*, vol. ci. p. 160), and by Cailletet and Bouty (*Journ. de Phys.* 1885, p. 297). The former's experiments were undertaken to test the

more quickly than the absolute temperature, so as to approach zero at a point not far below the temperature of nitrogen evaporating *in vacuo*. Cailletet and Bouty, using ethylene as the refrigerant, and experimenting at temperatures ranging from 0° C. to -100° C. and -123° C., constructed formulæ intended to give the coefficients of variation in electrical resistance for mercury, tin, silver, magnesium, aluminium, copper, iron, and platinum. Between 1892 and 1896 Dewar and Fleming carried out a large number of experiments to ascertain the changes of conductivity that occur in metals and alloys cooled in liquid air or oxygen to -200° C. The method employed was to obtain the material under investigation in the form of a fine regular wire and to wind it in a small coil; this was then plunged in the liquid and its resistance determined. The accompanying chart (Fig. 8) gives the results in a compendious form, the temperatures being expressed not in degrees of the ordinary air-thermometer scale, but in platinum degrees as given by one particular platinum resistance thermometer which was used throughout the investigation. A table showing the value of these degrees in degrees centigrade according to Dickson will be found in the *Phil. Mag.* for June 1898, p. 527; to give some idea of the relationship, it may be stated here that -100° of the platinum thermometer = -94°·2 C., -150° plat. = -140°·78 C., and -200° plat. = -185°·53 C. In general, the resistance of perfectly pure metals was greatly decreased by cold—so much so that, to judge by the course of the curves on the chart, it appeared probable that at the zero of absolute temperature resistance would vanish altogether and all pure metals become perfect conductors of electricity. This conclusion, however, has been rendered very doubtful by subsequent observations by Dewar, who found that with the still lower temperatures attainable with liquid hydrogen the increases of conductivity became less for each decrease of temperature, until a point was reached where the curves bent sharply round and any further diminution of resistance became very small; that is, the conductivity remained finite. The reduction in resistance of some of the metals at the boiling point of hydrogen is very remarkable. Thus copper has only $\frac{1}{10\frac{1}{2}}$ th, gold $\frac{1}{8}$ th, platinum $\frac{1}{3}$ th to $\frac{1}{4}$ th, silver $\frac{1}{2}$ th the resistance at melting ice, but iron is only reduced to $\frac{1}{8}$ th part of the same initial resistance. Table V. shows the progressive decrease of resistance for certain metals and one alloy as the temperature is lowered from that of boiling water down to that of liquid hydrogen boiling under reduced pressure; it also gives the "vanishing temperature," at which the conductivity would become perfect if the resistance continued to decrease in the same ratio with still lower temperatures, the values being derived from the extrapolation curves of the relation between resistance and temperature, according to Callendar and Dickson. It will be seen that many of the substances have actually been cooled to a lower temperature than that at which their resistance ought to vanish.

In the case of alloys and impure metals, cold brings about a much smaller decrease in resistivity, and the continuations of the curves at no time show any sign of passing through the zero point. The influence of the presence of impurities in minute quantities is strikingly shown in the case of bismuth. Various specimens of this metal, prepared with great care by purely chemical methods, gave in the hands of Dewar and Fleming some very anomalous results, appearing to reach at -80° C. a maximum of conductivity, and thereafter to increase in resistivity with decrease of temperature. But when the determinations were carried out on a sample of really pure bismuth prepared electrolytically, a normal curve

Fig. 8.—Chart of the Variation of Electrical Resistance of Pure Metals and Alloys with Temperature. (Dewar and Fleming.)

suggestion made by Clausius that the resistivity of pure metals is sensibly proportional to the absolute temperature; he worked with copper having a conductivity of 98 per cent., and carried out measurements at various temperatures, the lowest of which was that given by liquid nitrogen boiling under reduced pressure. His general conclusion was that the resistivity decreases much

was obtained corresponding to that given by other pure metals. As to alloys, there is usually some definite mixture of two pure metals which has a maximum resistivity, often greater than that of either of the constituents. It appears too that high, if not the highest, resistivity corresponds to possible chemical compounds of the two metals employed, *e.g.*, platinum 33 parts with silver 66 parts = PtAg₂; iron 80 with nickel 20 = Fe₄Ni; platinum 80 with iridium 20 = IrPt₄; and copper 70 with manganese 30 = Cu₂Mn. The product obtained by adding

a small quantity of one metal to another has a higher specific resistance than the predominant constituent, but the curve is parallel to, and therefore the same in shape as, that of the latter (cf. the curves for various mixtures of Al and Cu on the chart). The behaviour of carbon and of insulators like guttapercha, glass, ebonite, &c., is in complete contrast to the metals, for their resistivity steadily increases with cold. The thermoelectric properties of metals at low temperatures are discussed in the article THERMOELECTRICITY.

TABLE V.

Metals.	Platinum.	Platinum-rhodium Alloy.	Gold.	Silver.	Copper.	Iron.

Magnetic Phenomena.—Low temperatures have very marked effects upon the magnetic properties of various substances. Oxygen, long known to be slightly magnetic in the gaseous state, is powerfully attracted in the liquid condition by a magnet, and the same is true, though to a less extent, of liquid air, owing to the proportion of liquid oxygen it contains. A magnet of ordinary carbon steel has its magnetic moment temporarily increased by cooling, that is, after it has been brought to a permanent magnetic condition (“aged”). The effect of the first immersion of such a magnet in liquid air is a large diminution in its magnetic moment, which decreases still further when it is allowed to warm up to ordinary temperatures. A second cooling, however, increases the magnetic moment, which is again decreased by warming, and after a few repetitions of this cycle of cooling and heating the steel is brought into a condition such that its magnetic moment at the temperature of liquid air is greater by a constant percentage than it is at the ordinary temperature of the air. The increase of magnetic moment seems then to have reached a limit, because on further cooling to the temperature of liquid hydrogen hardly any further increase is observed. The percentage differs with the composition of the steel and with its physical condition. It is greater, for example, with a specimen tempered very soft than it is with another specimen of the same steel tempered glass hard. Aluminium steels show the same kind of phenomena as carbon ones, and the same may be said of chrome steels in the permanent condition, though the effect of the first cooling with them is a slight increase of magnetic moment. Nickel steels present some curious phenomena. When containing small percentages of nickel (*e.g.*, 0·84 or 3·82), they behave under changes of temperature much like carbon steel. With a sample containing 7·65 per cent., the phenomena after the permanent state had been reached were similar, but the first cooling produced a slight increase in magnetic moment. But steels containing 18·64 and 29 per cent. of nickel behaved very differently. The result of the first cooling was a reduction of the magnetic moment, to the extent of nearly 50 per cent. in the case of the former. Warming again brought about an increase, and the final condition was that at the temperature of liquid air the magnetic moment was always less than at ordinary temperatures. This anomaly is all the more remarkable in that the behaviour of pure nickel is normal, as also appears to be

generally the case with soft and hard iron. Silicon, tungsten, and manganese steels are also substantially normal in their behaviour, although there are considerable differences in the magnitudes of the variations they display (*Proc. Roy. Soc.* vol. lx. pp. 57 *et seq.*).

Low temperatures also affect the permeability of iron, *i.e.*, the degree of magnetization it is capable of acquiring under the influence of a certain magnetic force. With fine Swedish iron, carefully annealed, the permeability is slightly reduced by cooling to -185° C. Hard iron, however, in the same circumstances suffers a large increase of permeability. Unhardened steel pianoforte wire, again, behaves like soft annealed iron. As to hysteresis, low temperatures appear to produce no appreciable effect in soft iron; for hard iron the observations are undecisive.

Biological Research.—The effect of cold upon the life of living organisms is a matter of great intrinsic interest as well as of wide theoretical importance. Experiment indicates that moderately high temperatures are much more fatal, at least to the lower forms of life, than are exceedingly low ones. Professor M⁴Kendrick froze for an hour at a temperature of -182° C. samples of meat, milk, &c., in sealed tubes; when these were opened, after being kept at blood-heat for a few days, their contents were found to be quite putrid. More recently some more elaborate tests were carried out at the Jenner Institute of Preventive Medicine on a series of typical bacteria. These were exposed to the temperature of liquid air for twenty hours, but their vitality was not affected, their functional activities remained unimpaired, and the cultures which they yielded were normal in every respect. The same result was obtained when liquid hydrogen was substituted for air. A similar persistence of life has been demonstrated in seeds, even at the lowest temperatures; they were frozen for over 100 hours in liquid air at the instance of Messrs Brown and Escombe, with no other effect than to afflict their protoplasm with a certain inertness, from which it recovered with warmth. Subsequently commercial samples of barley, peas, and vegetable-marrow and mustard seeds were literally steeped for six hours in liquid hydrogen at the Royal Institution, yet when they were sown by Sir W. T. Thiselton Dyer at Kew in the ordinary way, the proportion in which germination occurred was no smaller than with other batches of the same seeds which had suffered no abnormal treatment. Mr. Harold Swinbank has found that exposure to liquid air has little or

no effect on the vitality of the tubercle bacillus, although by very prolonged exposures its virulence is modified to some extent; but alternate exposures to normal and very cold temperatures do have a decided effect both upon its vitality and its virulence. The suggestion once put forward by Lord Kelvin, that life may in the first instance have been conveyed to this planet on a meteorite, has been objected to on the ground that any living organism would have been killed before reaching the earth by its passage through the intense cold of interstellar space; the above experiments on the resistance to cold offered by seeds and bacteria show that this objection at least is not fatal to Lord Kelvin's idea.

At the Jenner Institute of Preventive Medicine liquid air has been brought into use as an agent in biological research. An inquiry into the intracellular constituents of the typhoid bacillus, initiated under the direction of Dr Allan Macfadyen, necessitated the separation of the cell-plasma of the organism. The method at first adopted for the disintegration of the bacteria was to mix them with silver-sand and churn the whole up in a closed vessel in which a series of horizontal vanes revolved at a high speed. But certain disadvantages attached to this procedure, and accordingly some means were sought to do away with the sand and triturate the bacilli *per se*. This was found in liquid air, which, as had long before been shown at the Royal Institution, has the power of reducing materials like grass or the leaves of plants to such a state of brittleness that they can easily be powdered in a mortar. By its aid a complete trituration of the typhoid bacilli has been accomplished at the Jenner Institute, and the same process, already applied with success also to yeast cells and animal cells, is being extended in other directions.

Industrial Applications.—While liquid air and liquid hydrogen are being used in scientific research to an extent which increases every day, but few applications to industrial purposes can as yet be reported. The temperatures they give used as simple refrigerants are much lower than are generally required industrially, and such cooling as is needed can be obtained quite satisfactorily, and far more cheaply, by refrigerating machinery employing more easily condensable gases. Their use as a source of motive power, again, is impracticable for any ordinary purposes, on the score of inconvenience and expense. Cases may be conceived of in which for special reasons it might prove advantageous to use liquid air, vaporized by heat derived from the surrounding atmosphere, to drive compressed-air engines, but any advantage so gained would certainly not be one of cheapness. No doubt the power of a waterfall running to waste might be temporarily conserved in the shape of liquid air, and thereby turned to useful effect. But the reduction of air to the liquid state is a process which involves the expenditure of a very large amount of energy, and it is not possible even to recover all that expended energy during the transition of the material back to the gaseous state. Hence to suggest that by using liquid air in a motor more power can be developed than was expended in producing the liquid air by which the motor is worked, is to propound a fallacy worse than perpetual motion, since such a process would have an efficiency of more than 100 per cent. Still, in conditions where economy is of no account, liquid air might perhaps, with effectively isolated storage, be utilized as a motive power, *e.g.*, to drive the engines of submarine boats and at the same time provide a supply of oxygen for the crew; even without being used in the engines, liquid air or oxygen might be found a convenient form in which to store the air necessary for respiration in such vessels. A use to

which liquid air machines have already been put to a limited extent is for obtaining oxygen from the atmosphere. Although when air is liquefied the oxygen and nitrogen are condensed simultaneously, yet owing to its greater volatility the latter boils off the more quickly of the two, so that the remaining liquid becomes gradually richer and richer in oxygen. The production of such highly oxygenated air was the object Linde had in view in constructing his liquid air machines, and it would find important applications in metallurgical and other operations, if only it could be produced at a sufficiently low cost. Pictet also has patented an apparatus designed to attain the same end, but no account of the practical results has appeared. Mention may be made of one interesting though minor application of this denitrogenized air, which is substantially liquid oxygen. If it be mixed with powdered charcoal, or finely divided organic bodies, it forms a liquid oxygen sponge which can be made by the aid of a detonator to explode with a violence comparable to that of dynamite. This explosive, which might properly be called an emergency one, has the disadvantage that it must be prepared on the spot where it is to be used and must be fired without delay, since the liquid evaporates in a short time and the explosive power is lost; but, on the other hand, if a charge fails to go off it has only to be left a few minutes, when it can be withdrawn without any danger of accidental explosion. Satisfactory results are claimed for experiments carried out with this substance in a coal mine at Pensberg, near Munich, and it has been used in the Simpton Tunnel works between Brigue and Domo d'Ossola.

For further information the reader may consult HARDIN, *Rise and Development of the Liquefaction of Gases* (New York, 1899), and LEFÈVRE, *La liquefaction des gaz et ses applications*; also the article CONDENSATION OF GASES in these volumes. But the literature of liquid gases is mostly contained in scientific periodicals and the proceedings of learned societies. Papers by Wroblewski and Olszewski on the liquefaction of oxygen and nitrogen may be found in the *Comptes Rendus*, vols. xcvi.-cii., and there are important memoirs by the former on the relations between the gaseous and liquid states and on the compressibility of hydrogen in *Wien. Akad. Sitzber.* vols. xciv. and xcvi.; his pamphlet *Comme l'air a été liquéfié* (Paris, 1885) should also be referred to. For Dewar's work, see *Proc. Roy. Inst.* from 1878 onwards, including "Solid Hydrogen," 1900; also "The Nadir of Temperature and Allied Problems" (Bakerian Lecture), *Proc. Roy. Soc.*, 1901. The researches of FLEMING and DEWAR on the electrical and magnetic properties of substances at low temperatures are described in *Proc. Roy. Soc.* vol. lx., and *Proc. Roy. Inst.*, 1896; see also "Electrical Resistance of Pure Metals, Alloys, and Non-Metals at the Boiling-Point of Oxygen," *Phil. Mag.* vol. xxxiv. (1892); "Electrical Resistance of Metals and Alloys at Temperatures approaching the Absolute Zero," *ib.* vol. xxxvi. (1893); "Thermoelectric Powers of Metals and Alloys between the Temperatures of the Boiling-Point of Water and the Boiling-Point of Liquid Air," *ib.* vol. xl. (1895); and papers on the dielectric constants of various substances at low temperatures in *Proc. Roy. Soc.* vols. lxi. and lxii. Optical and spectroscopic work by LIVEING and DEWAR on liquid gases is described in *Phil. Mag.* vols. xxxiv. (1892), xxxvi. (1893), xxxviii. (1894), and xl. (1895); for papers by the same authors on the separation and spectroscopic examination of the most volatile and least volatile constituents of atmospheric air, see *Proc. Roy. Soc.* vols. lxiv., lxvii., and lxviii. An account of the influence of very low temperatures on the germinative power of seeds is given by BROWN and ESCOMBE in *Proc. Roy. Soc.* vol. lxii., and by THISELTON DYER, *ib.* vol. lxv., and their effect on bacteria is discussed by MACFADYEN, *ib.* vol. lxvi.

(J. DR.)

Liquor Laws.—No period in history has been so fruitful in progressive liquor legislation as the decades since about 1880. The laws enacted, as well as the proposed legislation agitated before nearly every civilized government, reflect both a growing public consciousness of the evils of the drink traffic and determined efforts to overcome them. The modern tendency is to combat these evils by restrictive measures rather than by attempting a

general suppression of the sale of intoxicants, and to give the local community the right to choose between licence and the prohibition of the traffic, instead of applying prohibitory laws to entire states or countries. The liquor laws meriting special attention may be referred to three categories: I. the group of wholly new departures in the form of private or state monopolies; II. local option laws; and III. the various groups of licence laws.

I. The Scandinavian experiments, commonly designated as the *Gothenburg System*, the most widely known of modern liquor laws, afford a remarkable illustration of the power of wise national legislation combined with national temperance efforts to reduce the consumption of liquor. Although the original Gothenburg plan dates from 1865, it was not generally introduced throughout Sweden until 1880; the Norwegian adoption of it followed some time later. In both countries the central principle of the system is the elimination of private profit from the drink traffic by granting a monopoly of the retail sale of spirits to local corporations, under restrictions which prevent it from becoming a source of private enrichment, and which generally safeguard public interests both from the temperance and pecuniary point of view. In Norway especially the law of 1894, which expresses the advanced temperance opinion of the country, has enhanced the usefulness of the liquor corporations (*samlag*) and minimized the danger of abuses in administration. The non-inclusion of malt beverages and wine under the monopoly is perhaps the most serious obstacle to the success of the system as a means of combating intemperance. Nevertheless it is mainly due to the monopoly that the annual consumption of spirits in Sweden has been reduced to a third of what it was in 1850, and in Norway to a third of what it was in 1876. The Gothenburg plan has been followed in Finland, and has been experimented with by private associations in Great Britain.

The Government spirit monopoly in Russia owes its inception to Emperor Alexander III. It was, however, not introduced until January 1895, and then experimentally in four of the eastern provinces. The law became applicable to the entire empire in 1896, and is operative in about forty provinces with a total population of about seventy-five millions. The introduction of the monopoly, which was hastened by the famine of 1891 and the lamentable conditions it revealed, was not, it has been officially declared, for the purpose of increasing the drink revenue, but in order (1) "to save the peasantry from ruin" by protecting it from exploitation by persons licensed to sell spirits, and (2) to diminish drunkenness. Under the monopoly, which controls only the sale of spirituous liquors, spirits are retailed at the shops and depôts of the Government and at *traktirs* (establishments supplying both food and drink), restaurants and private resorts which sell on a Government commission. Except at a few restaurants of the highest class in cities and at railway stations, spirits are sold only in sealed bottles for consumption off the premises. In 1898 the Government licensed 357 wholesale and 17,240 retail shops. A sweeping reduction of places where liquor may be sold has everywhere followed the introduction of the monopoly. In several provinces the Government has endeavoured to establish tea-houses as counter-attractions to the grog-shops, by granting small subsidies to be expended by local temperance committees. In an address to the Emperor, under date of January 1899, the Russian minister of finance, having referred to the fact that as the people become accustomed to the new régime the consumption of spirits, which at first diminished, is reverting to the former figures, nevertheless continues: "The reports

addressed to your majesty by the governors of the provinces where the new system is in force, and the accounts communicated to the minister of finance by the highest ecclesiastical authorities, by the officials of the nobility, by the zemstvos, and by the municipalities, are almost unanimous in bearing evidence to the salutary effects of the reform. . . . Drunkenness has perceptibly diminished." The revenue from the system is much larger than was anticipated, the net profit in 1898 being about £3,000,000.

The *Dispensary System*, which is peculiar to the United States, takes either the form of a State monopoly of the retail traffic in alcoholic liquors, as in South Carolina, or the form of a local monopoly, as in North Carolina, Georgia, and Alabama, where the local communities can adopt the system or not, as they may determine. Under both forms the retail rate of alcoholic drink is taken out of private hands and carried on in dispensaries. In South Carolina, under an Act of 1892, variously amended from time to time, the state monopoly is managed by a state board of control of five members elected by the General Assembly: it appoints the county boards of control as well as a state commissioner, from whom all liquors sold by the local dispensers must be purchased. Liquors may only be sold for cash, between sunrise and sundown, in sealed packages containing not less than one half-pint or more than five gallons. Similar restrictions apply to the sale of malt beverages. The state virtually controls the distillation of spirits within its borders. The monopoly has a twofold aim: (1) to reduce the evil of the drink traffic by taking it out of private hands, and (2) to retain the entire profit for state and municipal purposes. Determined hostility to the system, mismanagement of its affairs, and adverse court decisions with regard to its constitutionality, have at different times come perilously near wrecking the monopoly. Now that the Dispensary Act has been upheld by the United States Supreme Court, the permanency of the system seems fairly well assured. Whatever the difference of opinion may be concerning the effect of the system on the consumption of spirits and public intoxication, it undoubtedly possesses some advantages of great merit which are more or less incident to any system that eliminates from the traffic the element of private profits. It has effected numerous administrative reforms of far-reaching consequence; it has abolished the saloon with its many dangerous accessories, and with it the domination of whisky rings in politics has become a thing of the past. A wise adjustment of the relation of the state to the local community is difficult under the South Carolina system, as under any state monopoly. As a revenue producer the system has not fulfilled expectations.

The Swiss *Alcohol Monopoly* of 1897 controls the importation, manufacture, and wholesale distribution of spirits in quantities of not less than 40 litres. The sale of liquor in smaller quantities is not regulated by the monopoly, but is subject to taxes imposed by the various cantons. In general the taxes are about three times higher than before 1887. The monopoly has suppressed the evil of the many small stills in agricultural districts, whose product, owing to primitive methods of manufacture and lack of rectification, found no market, but was consumed where produced, and caused much drunkenness. By abolishing cantonal and communal duties on beer and wine, as well as by removing other restrictions on their sale in quantities of more than two litres, the Government has carried out its policy of supplanting the use of spirits by that of fermented beverages. In consequence, a notable increase has taken place in the consumption of beer, while the consumption of spirits has decreased about 25 per cent. The law requires that one-tenth of the

revenue from the monopoly shall be applied to counteract alcoholism.

II. The principal of local option, or the right of the local community to forbid the sale of liquor within its own borders, has gained wide recognition and sanction, particularly in the United States, where it may be said to have become the alternative system to state prohibition and is supplanting the latter in popular favour. The right of choice between licence and local prohibition does not, however, imply an exercise of this right. All states with local option have some form of licence, the right to prohibit the traffic being exercised only in certain localities, even if applicable to all. In seventeen states local option is by direct popular vote applicable to all localities, both urban and rural; in six states by direct popular vote applicable to certain localities, or rural districts only; nine states have indirect local option, *i.e.*, through discretionary powers vested in city councils and other elective bodies; and in five states the right to vote is by "remonstrance," and by requiring the consent of qualified electors, property-holders, &c. Within the particular areas to which it has been applied, local option has, on the whole, been a success. It has banished the liquor traffic from immense areas. Moreover, the enforcement of the popular will as expressed in the vote has generally been free from the demoralizing effects attending attempts to suppress the traffic in cities under state prohibition. The value of local prohibition in populous centres, except where they have a safety valve through adjoining towns under licence, remains to be demonstrated.

In the Dominion of Canada, under the so-called Scott Act of 1878, which is a Federal law, counties and cities can by a majority vote prohibit the retail sale of liquor within their boundaries. Several provincial laws also recognize the principle of local option, but can only be taken advantage of by localities that have refused to adopt the prohibitory clauses of the Scott Act. Under provincial legislation, local option is usually exercised through discretionary powers vested in the licensing authorities. Local prohibition is successfully enforced throughout wide rural districts of the Dominion.

In Norway local vote on the retail traffic in spirits has been exercised in rural districts since 1845. By the law of 1894, however, which requires all retail trade in spirits to be placed under the monopolies (*samlag*), the establishment of a new *samlag*, or even the continuance of an old one, is made dependent upon a general vote of all residents in the district, both men and women, over twenty-five years of age; and the decision is binding for five years. All rural districts and about one-half of the towns are now under local prohibition. Practically the whole of rural Sweden is under local prohibition by virtue of a law of 1855.

New Zealand and Queensland are the two Australasian colonies granting full powers of local option, but little advantage has been taken of the privilege. Limited option prevails in the other colonies, with the exception of Tasmania. There are, of course, numerous examples in other parts of the world of the more or less successful adoption of local prohibition, but not as the result of expressed popular will.

III. Outside the United States and Canada, there have been few innovations in licensing methods or elaborations of licence systems deserving mention. In the United States the scheme known as the high-licence has claimed great attention; it was first introduced in Nebraska in 1881. In general, high-licence systems may be said to have two objects: (1) to reduce the volume of the traffic and place it under better control by charging high fees, (2) to divorce the trade as much as

possible from politics by selecting the proper licensing authorities. Massachusetts (law of 1888), Pennsylvania (law of 1888), and New York (Liquor Tax Law of 1896) furnish the most conspicuous examples of the working of high-licence. The Massachusetts law combines a very high fee (not less than \$1000 for a licence to sell for consumption on the premises) with statutory limitation of the number of licensed places according to population (1 to 1000 inhabitants in all places outside Boston, where the ratio is 1 to 500 inhabitants). Licences are usually issued by special commissioners. In Pennsylvania all licences are granted by the Court of Quarter Sessions in such number as it may deem necessary, with full powers to revoke any or all at the end of twelve months. The New York law centralizes the control of the excise business in a "State Commissioner of Excise," who issues tax receipts in place of the old-time licences, which are practically obtainable by all who can pay for them and are willing to conform to certain regulations. Under high-licence the restrictive measures and regulations are usually numerous and elaborate, with severe penalties for infraction. In the Canadian provinces it is sought to hold the liquor traffic in check not so much by the high-licence fees as by statutory limitations, and by requiring the applicant to obtain the consent of a majority, or even two-thirds, of the qualified voters of the electoral district in which he wishes to sell liquor. Especially drastic are the laws of Ontario and Nova Scotia, in respect both of the requirements before a licence can be issued and the regulations governing sales. Under any form of licence it has been found impossible to divorce drink-selling from politics. High-licence systems particularly give the communities too large a pecuniary interest in the traffic; and since he is obliged to pay a very high fee, the interest of the ordinary dealer in pushing sales is intensified. (See also under SOCIAL PROGRESS.)

(J. K.)

Liria, a town of Spain, in the province of Valencia, on the left bank of the river Guadalaviar, 15 miles north-west of Valencia. It is situated in a fertile plain which produces much wheat, wine, olives, and esparto grass.

There are several fine squares, and some ruins of an older city. The town hall and hospital are handsome structures. The parish church contains the family tombs of the dukes of Berwick and Liria. Population (1897), 8617.

Lisbon, the capital of the kingdom of Portugal, on the right bank of the Tagus, 10 miles above its mouth. Owing to the extreme irregularity of its surface, funicular railways and lifts are much used for communicating between the upper and lower parts of the city. Amongst the improvements of the last twenty years of the 19th century is the fine promenade, the Avenue of Liberty, with a monument of the deliverance from the yoke of Spain in 1640. Modern buildings include the central penitentiary, the new water-works, the central railway station, the medical school, and the "Figueira" market. The most notable of the museums are the colonial museum and the artillery museum. The city also possesses zoological gardens and an aquarium. One of the chief charms of Lisbon is the number of its public gardens, planted with tropical plants; and the Polytechnic School has a good botanical garden. The leading learned and scientific societies are the Society of Medical Sciences, the Geographical Society, the Academy of Sciences, the Association of Civil Engineers, the Academy of Fine Arts, the Artists' Union, the Royal Society of the Lovers of Music, the Royal Conservatory of Music, and the Commercial Athenæum. The educational institutions include the medico-surgical school, polytechnic school, military and naval schools, commercial, agricultural, and industrial institutes, trades' schools, school of the fine arts, a central lyceum, normal school, &c. There are hospitals for women, for contagious diseases, and a quarantine establishment. Lisbon is the seat of a commercial tribunal, and of the cardinal-patriarch of Lisbon. The port, which includes the out-ports of Nazareth and Setubal, was in 1897 entered and cleared by an aggregate of 5926 vessels of 7,087,815 tons. In 1899 the total aggregate of vessels was 5233 of 6,861,142 tons in Lisbon itself. In 1898 it had a fishing fleet of 593 vessels, manned by 2405 men, who took fish to the value of £115,780. The chief branches of industry carried on are the manufacture of pottery (21 factories), woollens, linens, cottons, and silks (36 factories), soap (13), chemicals (7), paper (5), alimentary pastes (12), glass (2), and factories for preserved foods, fruit, and fish, tobacco, phosphorus, &c. The growth of the population is shown in the following table:—

	Extent in acres.	Population, 1878.	Population, 1890.	Population, 1900.
Former area	2,938	187,404	240,712	...
Present ,,	11,152	242,297	301,206	357,000

The district of LISBON has an area of 16,900 square miles, and population 611,160 (1890), and 708,750 (1900), showing 42 inhabitants to the square mile. Wine is the most important product, the vintages including the wines of Collares, Torres, Bucellas, Lavradio, Carcavellos, and Setubal. In 1892 the vineyards covered 55,100 acres, and yielded 8,621,000 gallons of wine, valued at £149,350. In 1898 the wine production reached 31,751,799 gallons. Wheat and millet, olive oil, fruits, vegetables, and cattle are the other chief products. Mineral waters are plentiful (see ESTREMADURA). In addition to the industries of the city, there are in the district factories for biscuits, sardines, porcelain, dyeing, cottons, woollens, linen, and jute, cement, and corks.

(E. DE V.)

Lisburn, a town, and urban sanitary district, in the province of Ulster, Ireland, on the river Lagan, 8 miles south-south-west of Belfast by rail. It ceased to be a

parliamentary borough in 1885, and in 1898 the portion situated in Down was added to Antrim. Sir Richard Wallace presented a people's park to the town. Population (1881), 10,834; (1901), 11,459.

Liskeard, a municipal borough, market town, and railway station, in the Bodmin parliamentary division (since 1885) of Cornwall, England, 18 miles west-north-west of Plymouth. St Martin's church has been restored. A cottage hospital and public buildings (containing a literary institute and a school of art) and a public library have been erected. The Caradon copper mines are no longer worked. There are a woollen mill and a foundry. Area, 2704 acres. Population (1881), 4536; (1901), 4011.

Lissa, an Austrian island in the Adriatic, belonging to the province of Dalmatia. Population (1890), 8674; (1900), 9918. The chief town, of the same name, has a population of 5261. Its harbour is strongly fortified. Comisa, on the west side, in a deep bay, is also a steamship station. Population, 4657.

Lister, Joseph Lister, 1st BARON (1827—), English surgeon, was born at Upton, in Essex, on the 5th of April 1827. His father, Joseph Jackson Lister, F.R.S., was eminent in science, especially in optical science, his chief claim to remembrance being that by certain improvements in lenses he raised the compound microscope from the position of a scientific toy, "distorting as much as it magnified," to its present place as a powerful engine of research. Other members of Lord Lister's family were eminent in natural science. In his boyhood Joseph Lister was educated at Quaker schools; first at Hitchin in Hertfordshire, and afterwards at Tottenham, near London. In the year 1844 he entered University College, London, as a student in arts, and took his B.A. degree at the University of London in 1847. He continued at University College as a medical student, and became M.B. and F.R.C.S. in 1852. Lister had a natural bent to science, which brought him into intimate association with some of the ablest men of the staff of his teachers, among whom, at this period of his life, Graham, Sharpey, and Wharton Jones may be specially mentioned. The keen young student was not long in bringing his faculties to bear upon pathology and the practice of medicine. While house-surgeon at University College Hospital, he had charge of certain cases during an outbreak of hospital gangrene, and carefully observed the phenomena of the disease and the effects of treatment upon it. He was thus early led to suspect the parasitic nature of the disorder, and searched with the microscope the material of the spreading sore, in the hope of discovering in it some invading fungus; he soon convinced himself of the cardinal truth that its causes were purely local. He also minutely investigated cases of pyæmia, another terrible scourge of hospitals at that time, and made *camera lucida* sketches of the appearances revealed by the microscope.

To realize Lister's work it is necessary to remember the condition of surgical practice at that date. About the middle of the 19th century the introduction of anæsthetics had relieved the patient of much of the horror of the knife, and the surgeon of the duty of speed in his work. The agony of the sufferer had naturally and rightly compelled the public to demand rapid if not slapdash surgery, and the surgeon to pride himself on it. Within decent limits of precision, the quickest craftsman was the best. This rivalry was as unfortunate as it was unavoidable. The operation once begun was hurried through with the utmost rapidity, while there was little time to deliberate upon the conditions revealed, or for niceties of adaptation. With anæsthetics this state of

things at any rate was changed. The pain of the operation itself no longer counted, and the surgeon was enabled not only to be as cautious and sedulous as dexterous, but also to venture upon long, profound, and intricate operations which before had been out of the question. Yet unhappily this new enfranchisement seemed to be but an ironical liberty of Nature, who with the other hand took away what she had given. Direct healing of surgical wounds ("by first intention"), far from being the rule, was a piece of luck too rare to enter into the calculations of the operator; while of the graver surgical undertakings, however successful mechanically, the mortality by sepsis was ghastly. At all times suppuration, phagedæna, and septic poisonings of the system carried away even the most promising patients and followed even trifling operations. Often, too, these diseases rose to the height of epidemic pestilences, so that patients, however extreme their need, dreaded the very name of hospital, and the most skilful surgeons distrusted their own craft. New hospitals or new wards were built, yet after a very short time the new became as pestiferous as the old; and even scrupulous care in ventilation and housemaids' cleanliness failed to prevent the devastation. Surgery had enlarged its freedom, but only to find the weight of its new responsibilities more than it could bear.

When Lister was appointed to the chair of surgery in Glasgow the infirmary of that city was a hotbed of septic disease; so much so that his hospital visits evidently distressed him greatly. Windows were widely opened, piles of clean towels were supplied, but still the pestilence stalked through the wards. The building stands to-day as it stood then, with no substantial alteration; but by the genius of Lister its surgical wards are now as free from septic accidents as the most modern hospital in the land. James Simpson, early in the 'sixties, pathetically denounced the awful mortality of operations in hospitals, and indeed uttered desperate protests against the hospital system itself; yet, not long afterwards, Lister came to prove that it was not in the hospital that the causes of that mortality lay hidden, but in the operator himself, his tools, and his assistants. Happily this beneficent discovery was made in time to preserve the inestimable boon of the hospital system from the counsels of despair. When Lister took up the task speculation was on the wrong tack; the oxygen of the air was then supposed to be the chief cause of the dissolution of the tissues, and to prevent access of air was impossible. For instance, a simple fracture, as of a bone of the leg, would do perfectly well, while in the very next bed a compound fracture—one, that is, where the skin is lacerated, and access to the seat of injury opened out—would go disastrously wrong. If the limb were amputated, a large proportion of such cases of amputation succumbed to septic poisoning—the fell and occult foe.

On graduation as bachelor of medicine, Lister went to Edinburgh, where he soon afterwards became house-surgeon to Mr Syme; and he was much impressed by the skill and judgment of this great surgeon, and also by the superiority of his method of dressing recent wounds with dry lint, as compared with the "water dressing" in use at University College. Yet under these more favourable conditions the amelioration was only one of degree; in most wounds indeed "union by first intention" was rendered impossible by the presence of the silk ligatures employed for arresting bleeding, for these could come away only by a process of suppuration. On the expiry of his house-surgeoncy in Edinburgh, Lister started in that city an extra-academical course of lectures on surgery; and in preparation for these he entered on a series of investigations into inflammation and allied subjects. These

researches, which were detailed fully in three papers in *Phil. Trans.*, 1859, and in his Croonian lecture to the Royal Society in 1863, testified to an earnestness of purpose, a persevering accuracy of observation and experiment, and an insight of scientific conception which show that if Lister had never developed the aseptic method of surgery, he would have taken a very high place in pathology. In any case his earlier work was an indispensable preliminary to his later labours. In his speech in Paris at the Thirteenth International Congress of Medicine in 1900, Lord Lister said that he had done no more than seize upon Pasteur's discoveries and apply them to surgery. But though Lister saw the vast importance of the discoveries of Pasteur, he saw it because he was watching on the heights; and he was watching there alone. From Pas-

LORD LISTER.

(From a photograph by Elliott and Fry, London.)

teur Lister derived no doubt two fruitful ideas: first, that decomposition in organic substances is due to living "germs"; and, secondly, that these lowly and minute forms of vegetable life spring always, like higher organisms, from parents like themselves, and cannot arise *de novo* in the animal body. After his appointment to the Glasgow chair in 1860, Lister had continued his researches on inflammation; and he had long been led to suspect that decomposition of the blood in the wound was the main cause of suppuration. The two great theories established by Pasteur seemed to Lister to open out the possibility of what had before appeared hopeless—namely, the prevention of putrefaction in the wound, and consequently the forestalling of suppuration. To exclude the oxygen of the air from wounds was impossible, but it might be practicable to protect them from microbes.

The first attempt to realize this idea was made upon compound fractures; and the means first employed was carbolic acid, the remarkable efficacy of which in deodorizing sewage made Lister regard it as a very powerful germicide. It was applied to the wound undiluted, so as to form with the blood a dense crust, the surface of which was painted daily with the acid till all danger had

passed. The results, after a first failure, were in the highest degree satisfactory, so that, as Lister said in his presidential address to the British Association in Liverpool, he "had the joy of seeing these formidable injuries follow the same safe and tranquil course as simple fractures." The caustic property of undiluted carbolic acid, though insignificant in comparison with the far greater evils to be avoided in compound fracture, made it quite unsuited for general surgery. In order to make it applicable to the treatment of abscesses and incised wounds, it was necessary to mitigate its action by blending it with some inert body; and the endeavour to find the best medium for this purpose, such as to combine perfect antiseptic efficiency with the least possible irritation of the tissues, formed the subject of experiments continued for many years in the laboratory and in the ward. At one stage in these inquiries an attempt was made to provide an atmosphere free from living organisms by means of a fine spray of a watery solution of carbolic acid; for it was then supposed by Lister to be necessary not only to purify the surgeon's hands and instruments and the skin of the patient about the seat of operation, but also to wage war with the microbes which, as Pasteur had shown, people every cubic inch of the air of an inhabited room. Under the use of the spray better results were obtained than ever before, and this success encouraged its use. But researches carried on for several years into the relations of the blood to micro-organisms led Lister to doubt the harmfulness of the atmospheric dust. At the London Congress in 1881 he narrated experiments which proved that the serum of the blood is a very unfavourable soil for the development of the bacteria diffused through the air, and others which showed that the cells of an organizing blood-clot have a very remarkable power of disposing of microbes and of limiting their advance. Hence he considered it probable that in surgical operations the atmosphere might be disregarded altogether.¹ As long, however, as this was only a matter of probability, he did not dare to discard the spray. But at length, at the Berlin Congress in 1890, he was able to announce that the certainty he had so long desired had been arrived at. A careful consideration of the physical constitution of the spray had shown him that the microbes of the dust involved in its vortex could not possibly have their vitality destroyed or even impaired by it. Such being the case, the uniform success obtained when he had trusted the spray implicitly as an aseptic atmosphere, abandoning completely certain other precautions which he had before deemed essential, proved conclusively to his mind that the air might safely be left entirely out of consideration in operating.² Thus he learnt that not the spray only, but all antiseptic irrigations or washings of the wound also, with their attendant irritation of the cut surfaces, might be dispensed with—a great simplification, indirectly due to experiments with the spray. The spray had also served a very useful purpose by maintaining a pure condition of the *entourage* of the operation; not indeed in the way for which it was devised, but as a very mild form of irrigation. And Lister took care to emphasize the necessity for redoubled vigilance on the part of the surgeon and his assistants when this "unconscious caretaker," as he called it, had been discarded.

The announcement that he had given up the spray was absurdly interpreted in some quarters to mean that he had virtually abandoned his theory and his antiseptic methods. The truth is that the spray was only one of

many devices tried for a while in the course of the long-continued endeavour to apply the antiseptic principle to the best advantage, and abandoned in favour of something better. Two main objects were always kept steadily in view by him—during the operation to guard the wound against septic microbes by such means as existing knowledge indicated, and afterwards to protect it against their introduction, avoiding at the same time all needless irritation of the tissues by the antiseptic. Upon the technical methods of attaining these ends this is not the place to enlarge; suffice it to say that the endowments and the industry of the discoverer, as seen in the rapidity and flexibility of mind with which he seized upon and selected the best means, were little less remarkable than the activity of the same faculties in his original ideas.

To illustrate this opinion, his work on the ligature may be taken. It had long been the universal practice of surgeons to employ threads of silk or flax for tying arteries, long ends being left to provide escape of the pus (invariably formed during the tedious process of the separation of the ligature) together with the portion of the arterial coats included in the knot. Lister hoped that if, by antiseptic means, the thread were deprived of living microbes, it would no longer cause suppuration, but might be left with short cut ends to become embedded permanently among the tissues of the wound, which thus would be allowed to heal by primary union throughout. A trial of this method upon the carotid artery of a horse having proved perfectly successful, he applied it in a case of aneurysm in the human subject; and here again the immediate results were all that could be desired. But a year later, the patient having died from other causes, the necropsy showed remnants of the silk thread incompletely absorbed, with appearances around them which seemed to indicate that they had been acting as causes of disturbance. Thus was suggested to him the idea of employing for the ligature some material susceptible of more speedy absorption; and the antiseptic treatment of contused wounds having shown that dead tissue, if protected from putrefaction, is removed by the surrounding structures without the intervention of suppuration, he resolved to try a thread of some such nature. Catgut, which is prepared from one of the constituents of the small intestine of the sheep, after steeping in a solution of carbolic acid, was used in a preliminary trial upon the carotid artery of a calf. The animal was killed a month later, when, on dissection, a very beautiful result was disclosed. The catgut, though removed, had not been simply absorbed; *pari passu* with its gradual removal, fibrous tissue of new formation had been laid down, so that in place of the dead catgut was seen a living ligature embracing the artery and incorporated with it. The wound meanwhile had healed without a trace of suppuration. This success appeared to justify the use of the catgut ligature in the human subject, and for a while the results were entirely satisfactory. But though this was the case with the old samples of catgut first employed, which, as Lister was afterwards led to believe, had been "seasoned" by long keeping, it was found that when catgut was used fresh as it comes from the makers, it was unsuited in various ways for surgical purposes. The attempt by special preparation to obtain an article in all respects trustworthy engaged his attention from time to time for years afterwards. To quote the words of Sir Hector Cameron, who was for several years assistant to Lord Lister, it required "labour and toilsome investigation and experiment of which few can have any adequate idea."

In 1869 Lister succeeded his father-in-law, Syme, in the chair of clinical surgery of Edinburgh. In 1877 he accepted an invitation to the chair of surgery at King's College, London, in the anticipation that here he would be

¹ See *Trans. of the International Medical Congress*, 1881, vol. ii. p. 373.

² See *Verhandlungen des X internationalen Congresses*, Bd. i. p. 33.

more centrally placed for communication with the surgical world at home and abroad, and might thus exercise his beneficent mission to more immediate advantage. In 1896 Lister retired from practice, but not from scientific study. From 1895 to 1900 he was President of the Royal Society. In 1883 he was created a baronet, and in 1897 he was raised to the peerage as Baron Lister of Lyme Regis. Among the Coronation honours in 1902, he was nominated an original member of the new Order of Merit.

In England Lister's teaching was slow in making its way. The leading surgeons of Germany were among the first to seize upon the new idea with avidity and practical success; so early as 1875, in the course of a tour he made on the Continent, great festivals were held in his honour in Munich and Leipzig. The countrymen of Pasteur did not lag far behind; and it is no exaggeration to speak of Lister's appearances in foreign countries at this time as triumphal, not in respect of formal honours only, but also of an enthusiasm almost stupendous.

The relation of Semmelweiss to Lister is of historical importance. Lister's work on the antiseptic system began in 1864; his first publication on the subject was in March 1867. At this date, and for long afterwards, the very name of Semmelweiss was unknown, or ignored, not only by French and Germans, but also by his own Hungarian people; and this neglect broke his heart. The French Academy pronounced against his opinions, and so did the highest pathological authority in Germany. In England, till long after his death, probably his name was not so much as mentioned. In the early 'seventies Lister's method was in full operation in Hungary as elsewhere, yet none of the surgeons of Budapest ever mentioned Semmelweiss; not even when, in 1883, they gave a great banquet to Lister, followed by a torchlight procession of the students. It was after this occasion that Dr Duka, a Hungarian physician practising in London, wrote a biography of Semmelweiss, which he sent to Lister, and thus brought the name of Semmelweiss before him for the first time. Thenceforth Lister generously regarded Semmelweiss as in some measure his forerunner; though we may point out that Semmelweiss was not aware of the microbic origin of septic poisons, nor were his methods, magnificent as was their success in lying-in hospitals, suitable for surgical work.

In public Lord Lister's speeches were simple, clear, and graceful, avoiding rhetorical display, earnest for the truth, jealous for his science and art, forgetful of himself. His writings, in like manner plain, lucid, and forcible, scarcely betray the labour and thought of their production. With the courtesy and serenity of his carriage he combined a passionate humanity, so often characteristic of those who come of the Society of Friends, and a simple love of truth which showed itself in his generous encouragement of younger workers.

Liszt, Franz (1811–1886), Hungarian pianist and composer, was born on 22nd October 1811, at Raiding, in Hungary. His appeal to musicians was made in a three-fold capacity, and we have, therefore, to deal with Liszt the unrivalled pianoforte virtuoso (1830–48); Liszt the conductor of the "music of the future" at Weimar, the teacher of Tausig, Bülow, and a host of lesser pianists, the eloquent writer on music and musicians, the champion of Berlioz and Wagner (1848–61); and Liszt the prolific composer, who for some five-and-thirty years continued to put forth pianoforte pieces, songs, symphonic orchestral pieces, cantatas, masses, psalms, and oratorios (1847–82). As virtuoso he held his own for the entire period during which he chose to appear in public; but the militant conductor and prophet of Wagner had a hard time of it,

and the composer's place is still in dispute. Liszt's father, a clerk to the agent of the Esterhazy estates and an amateur musician of some attainment, was Hungarian by birth and ancestry, his mother an Austrian-German. The boy's gifts attracted the attention of certain Hungarian magnates, who furnished a sum of 600 gulden annually for some years to enable him to study music at Vienna and Paris. At Vienna he had lessons in pianoforte playing from Carl Czerny of "Velocity" fame, and from Salieri in harmony and analysis of scores. In his eleventh year he began to play in public there, and Beethoven came to his second concert in April 1823. During the three years following he played in Paris, the French provinces, and Switzerland, and paid three visits to England. In Paris he had composition lessons from Paër, and a six months' course of lessons in counterpoint from Reicha. In the autumn of 1825 the handsome and fascinating *enfant gâté* of the salons and ateliers—"La neuvième merveille du monde"—had the luck to get an operetta (*Don Sancho*) performed three times at the Académie Royale. The score was accidentally destroyed by fire, but a set of studies *à la Czerny* and Cramer, belonging to 1826 and published at Marseilles as 12 Études, op. i., is extant, and shows remarkable precocity. After the death of his father in 1828 young Liszt led the life of a teacher of the pianoforte in Paris, got through a good deal of miscellaneous reading, and felt the influence of the religious, literary, and political aspirations of the time. He attended the meetings of the Saint-Simonists, lent an ear to the romantic mysticism of Père Enfantin, and later to the teaching of Abbé Lamennais. He also played Beethoven and Weber in public—a very courageous thing in those days. The appearance of the violinist Paganini in Paris, 1831, marks the starting-point of the supreme eminence Liszt ultimately attained as a virtuoso. Paganini's marvellous technique inspired him to practise as no pianist had ever practised before. He tried to find equivalents for Paganini's effects, transcribed his violin caprices for the piano, and perfected his own technique to an extraordinary degree. After Paganini he received a fresh impulse from the playing and the compositions of Chopin, who arrived in 1831, and yet another impulse of equal force from a performance of Berlioz's "Symphonie Fantastique, épisode de la vie d'un artiste," in 1832. Liszt transcribed this work, and its influence ultimately led him to the composition of his "Poèmes symphoniques" and other examples of orchestral programme-music. From 1833 to 1848—when he gave up playing in public—he was greeted with frantic applause as the prince of pianists. Five years (1835–40) spent in semi-retirement in the company of Madame la Comtesse D'Agoult (George Sand's friend and would-be rival, known in literary circles as Daniel Stern) in Switzerland and Italy, were devoted to further study in playing and composition, and were interrupted only by occasional appearances at Geneva, Milan, Florence, and Rome, and by annual visits to Paris. During one of these visits the famous contest with Thalberg took place (1837). The enthusiasm aroused by Liszt's playing and his personality—the two are inseparable—reached a climax at Vienna and Budapest in 1839–40, when he received a patent of nobility from the emperor of Austria, and a sword of honour from the magnates of Hungary in the name of the nation. During the eight years following he was heard at all the principal centres—including London, Leipzig, Berlin, Copenhagen, St Petersburg, Moscow, Warsaw, Constantinople, Lisbon, and Madrid. He gained much money, and gave large sums in charity. His munificence with regard to the Beethoven statue at Bonn made a great stir. The subscriptions having come in but sparsely, Liszt took the matter in hand, and the monument was completed at his

expense, and unveiled at a musical festival conducted by Spohr and himself in 1845. In 1848 he settled at Weimar with Madame la Princesse Sayn-Wittgenstein, and remained there till 1861. During this period he acted as conductor at court concerts and on special occasions at the theatre, gave lessons to a number of pianists, wrote articles of permanent value on certain works of Berlioz and the early operas of Wagner, and produced those orchestral and choral pieces upon which his reputation as a composer mainly depends. His ambition to found a school of composers as well as a school of pianists met with complete success on the one hand and partial failure on the other. His efforts on behalf of Wagner, who was then an exile in Switzerland, culminated in the first performance of *Lohengrin* on 28th August 1850, before a special audience assembled from far and near. Among the works produced for the first time or rehearsed with a view to the furtherance of musical art were Wagner's *Tannhäuser*, *Der fliegende Holländer*, *Das Liebesmahl der Apostel*, and *Eine Faust Overture*, Berlioz's *Benvenuto Cellini*, the *Symphonie Fantastique*, *Harold en Italie*, *Roméo et Juliette*, *La Damnation de Faust*, and *L'Enfance du Christ*—the last two conducted by the composer—Schumann's *Geneveva*, *Paradise and the Peri*, the music to *Manfred* and to *Faust*, Weber's *Euryanthe*, Schubert's *Alfonso und Estrella*, Raff's *König Alfred*, Cornelius's *Der Barbier von Bagdad*, and many more. It was Liszt's habit to recommend novelties to the public by explanatory articles or essays, which were written in French (some for the *Journal des Débats* and the *Gazette Musicale* of Paris) and translated for the journals of Weimar and Leipzig,—thus his two masterpieces of sympathetic criticism, the essays *Lohengrin et Tannhäuser à Weimar*, and *Harold en Italie*, found many readers and proved very effective. They are now included, together with articles on Schumann and Schubert, and the elaborate and rather high-flown essays on Chopin and *Des Bohémiens et de leur musique en Hongrie* (the latter certainly, and the former probably, written in collaboration with Madame de Wittgenstein), in his *Gesammelte Schriften* (6 volumes, Leipzig). The compositions belonging to the period of his residence at Weimar comprise two pianoforte concertos, in E flat and in A, the "Todtentanz," the "Concerto pathétique" for two pianos, the solo sonata "An Robert Schumann," sundry "Études," fifteen "Rhapsodies Hongroises," twelve orchestral "Poèmes symphoniques," "Eine Faust Symphonie," and "Eine Symphonie zu Dante's 'Divina Commedia,'" the "13th Psalm" for tenor solo, chorus, and orchestra, the choruses to Herder's dramatic scenes "Prometheus," and the "Missa solennis" known as the "Graner Fest Messe." Liszt retired to Rome in 1861, and joined the Franciscan order in 1865. From 1869 onwards Abbé Liszt divided his time between Rome and Weimar, where during the summer months he received pupils—gratis as formerly—and, from 1876 up to his death at Bay-

reuth on the 31st July 1886, he also taught for several months every year at the Hungarian Conservatoire of Budapest.

About Liszt's pianoforte technique in general it may be said that it derives its efficiency from the teaching of Czerny, who brought up his pupil on Mozart, a little Bach and Beethoven, a good deal of Clementi and Hummel, and a good deal of his (Czerny's) own work. Classicism in the shape of solid, respectable Hummel on the one hand, and Carl Czerny, a trifle flippant, perhaps, and inclined to appeal to the gallery, on the other—these gave the musical parentage of young Liszt. Then appears the Parisian Ineroyable and grand seigneur—"Monsieur Lits," as the Parisians called him. Later, we find him imitating Paganini and Chopin, and at the same time making a really passionate and deep study of Beethoven, Weber, Schubert, Berlioz. Thus gradually was formed the master of style—whose command of the instrument was supreme, and who played like an inspired poet. Liszt's strange musical nature was long in maturing its fruits. At the pianoforte his achievements culminate in the two books of studies, twice rewritten, and finally published in 1852 as *Études d'exécution transcendante*, the *Études de concert*, and the *Paganini Studies*; the two concertos and the *Todtentanz*, the *Sonata in B minor*, the *Hungarian Rhapsodies*, and the fine transcriptions of Beethoven's symphonies (the 9th for two pianofortes as well as solo), and of Berlioz's *Symphonie fantastique*, and the symphony, *Harold en Italie*. In his orchestral pieces Liszt appears—next to Berlioz—as the most conspicuous and most thorough-going representative of programme

FRANZ LISZT.

(From a photograph by Elliott and Fry, London.)

music, i.e., instrumental music expressly contrived to illustrate in detail some poem or some succession of ideas or pictures. It was Liszt's aim to bring about a direct alliance or amalgamation of instrumental music with poetry. To effect this he made use of the means of musical expression for purposes of illustration, and relied on points of support outside the pale of music proper. There is always danger of failure when an attempt is thus made to connect instrumental music with conceptions not in themselves musical, for the order of the ideas that serve as a programme is apt to interfere with the order which the musical exposition naturally assumes—and the result in most cases is but an amalgam of irreconcilable materials. In pieces such as Liszt's "Poèmes symphoniques," *Ce qu'on entend sur la montagne* (1848–1856)—after a poem by Victor Hugo—and *Die Ideale* (1853–57)—after a poem by Schiller—the hearer is bewildered by a series of startling orchestral effects which succeed one another apparently without rhyme or reason. The music does not conform to any sufficiently definite musical plan—it is, in fact, hardly intelligible as music without reference to the programme. Liszt's masterpiece in orchestral music is the *Dante Symphony* (1847–55), the subject of which was particularly well suited to his temperament, and offered good chances for the display of

his peculiar powers as a master of instrumental effect. By the side of it ranks the *Faust Symphony* (1854-57), in which the moods of Goethe's characters—Faust, Gretchen, and Mephistopheles—are depicted in three instrumental movements, with a chorus of male voices, supplying a kind of comment, by way of close. The method of presentation in both symphonies is by means of representative themes (*Leitmotif*), and their combination and interaction. Incidents of the poem or the play are illustrated or alluded to as may be convenient, and the exigencies of musical form are not unfrequently disregarded for the sake of special effects. Of the twelve *Poèmes Symphoniques*, *Orphée* is the most consistent from a musical point of view, and is exquisitely scored. Melodious, effective, readily intelligible, with a dash of the commonplace, *Les Préludes*, *Tasso*, *Mazeppa*, and *Fest-Klänge* bid for popularity. In these pieces, as in almost every production of his, in lieu of melody Liszt offers fragments of melody—touching and beautiful, it may be, or passionate, or tinged with triviality; in lieu of a rational distribution of centres of harmony in accordance with some definite plan, he presents clever combinations of chords and ingenious modulations from point to point; in lieu of musical logic and consistency of design, he is content with rhapsodical improvisation. The power of persistence seems wanting. The musical growth is spoilt, the development of the themes is stopped, or prevented, by some reference to extraneous ideas. Everywhere the programme stands in the way. In much of Liszt's vocal music, particularly in the songs and choral pieces written to German words, an annoying discrepancy is felt to exist between the true sound of the words and the musical accents. The music is generally emotional, the expression direct and passionate; there is no lack of melodic charm and originality, yet the total effect is frequently disappointing. In the choral numbers of the five masses, and in the oratorios *Die Heilige Elisabeth* and *Christus*, the rarity of fugal polyphony acts as a drawback. Its almost complete absence in some of these works makes for monotony and produces a sense of dullness, which may not be inherent in all the details of the music, but is none the less distinctly present.

A thematic catalogue of Liszt's works was published during his lifetime. The rather indiscriminate and verbose biography by Lina Ramann (3 vols., Leipzig) is trustworthy as to facts and dates.

Omitting trifles and all publications that have been cancelled, the following list of compositions may be taken as fairly comprehensive:—

Pianoforte Pieces.—Études d'exécution transcendante; Études de concert; Zwei Etuden, Waldesrauschen, Gnomentanz; Ab Irato; Paganini Studies; Années de Pèlerinage, 3 sets; Harmonies poétiques et religieuses, 1-10; Consolations, 1-6; Ave Maria in E; Sonata in B minor; Konzert-Solo in E minor; Scherzo und Marsch; Ballades, I, II; Polonaises, I, II; Apparitions, 1-3; Berceuse; Valse impromptu; Mazurka brillant; 3 Caprices Valses; Galop chromatique; Mephisto-Walzer, I, II, III, and Polka; Zwei Legenden, "Die Vogelpredigt," "Der heilige Franciscus auf den Wogen schreitend"; "Der Weihnachtsbaum," 1-12; Sarabande und Chaconne ("Almira"); Elegies, I, II, and III; La lugubre Gondola; Dem Andenken Petöfi's; Mosonyi's Grabgeleit; Romance oubliée; Valses oubliées, 1-3; Liebesträume, 1-3 (originally songs); Hexameron; Rhapsodies Hongroises, 1-18.

Pieces for Two Pianos.—Concerto pathétique (identical with the Konzert-Solo in E minor); Dante symphony; Faust symphony; Poèmes symphoniques, 1-12; Beethoven's 9th symphony.

Pianoforte with Orchestra.—Concertos I. in E flat, II. in A; Todtentanz; Fantasie ueber Motif aus Beethoven's "Ruinen von Athen"; Fantasie ueber Ungarische National Melodien; Schubert's Fantasia in C; Weber's Polacca in E.

Fantaisies de Concert for Piano Solo.—Don Juan; Norma; Son-nambula; I Puritani; Lucia, I, II; Lucrezia, I, II; La Juive; Robert le Diable; Les Huguenots; Le Prophète, 1-4. *Paraphrases*, Auber, Tarantella di bravura (Masaniello); Verdi, Rigoletto, Ernani, Il Trovatore; Mendelssohn, "Hochzeitsmarsch und Elfenreigen"; Gounod, Valse de Faust, Les Adieux de Roméo et Juliette; Tschai-kowsky, Polonaise; Hergomyiski, Tarantelle; Cui, Tarantella;

Saint-Saëns, Danse macabre; Schubert, Soirées de Vienne, Valses caprices, 1-9.

Transcriptions.—Beethoven's Nine Symphonies; Berlioz's "Symphonie fantastique," "Harold en Italie"; Bénédiction et Serment (Benvenuto Cellini); Danse des Sylphes (Damnation de Faust); Weber's overtures, Der Freischütz, Euryanthe, Oberon, Jubilee; Beethoven's and Hummel's Septets; Schubert's Divertissement à la Hongroise; Beethoven's Concertos in C minor, G and E flat (orchestra for a second piano); Wagner's Tannhäuser overture, march, romance, chorus of pilgrims; Lohengrin, Festzug und Brautlied, Elsa's Brautgang, Elsa's Traum, Lohengrin's Verweiss an Elsa; Fliegender Holländer, Spinnlied; Rienzi, Gebet; Rheingold, Walhall; Meistersinger, "Am stillen Herd"; Tristan, Isolde's Liebestod; Chopin's six Chants Polonais; Meyerbeer's Schillermarsch; Bach's six organ Preludes and Fugues; Prelude and Fugue in G minor; Beethoven, Adelaide; 6 miscellaneous and 6 Geistliche Lieder; Liederkreis; Rossini's Les Soirées musicales; Schubert, 59 songs; Schumann, 13 songs; Mendelssohn, 8 songs; Robert Franz, 13 songs.

Organ Pieces.—Missa pro organo; Fantasia and Fugue, "Ad nos, ad salutarem undam"; B-A-C-H Fugue; Variations on Bach's Basso continuo, "Weinen, Klagen"; Bach's Introduction and Fugue, "Ich hatte viel Bekümmerniss"; Bach's Choral Fugue, "Lob und Ehre"; Nicolai's Kirchliche Festouvertüre, "Ein feste Burg"; Allegri's Miserere; Mozart's Ave Verum; Arcadelt's Ave Maria; Lasso's Regina Cœli.

Orchestral Pieces.—Eine Symphonie zu Dante's "Divina Commedia"; Eine Faust Symphonie; Poèmes symphoniques: 1. "Ce qu'on entend sur la montagne"; 2. Tasso; 3. Les Préludes; 4. Orphée; 5. Prométhée; 6. Mazeppa; 7. Fest-Klänge; 8. Héroïde funèbre; 9. Hungaria; 10. Hamlet; 11. Hunnenschlacht; 12. Die Ideale; Zwei Episoden aus Lenau's Faust: I. Der nächtliche Zug, II. Der Tanz in der Dorfschenke; Marches, Rakoczy, Goethe, Huldigung, "Vom Fels zum Meer" (for a military band); Ungarischer, Heroischer, and Sturm-marsch; Le Triomphe funèbre du Tasse; "Von der Wiege bis zum Grab"; six Hungarian rhapsodies; four marches; four songs, and Die Allmacht, by Schubert.

Vocal Music.—Oratorios: "Die Legende von der Heiligen Elisabeth," "Christus," "Stanislaus" (unfinished). Masses: Missa solennis for the inauguration of the cathedral at Gran; Ungarische Krönungs-messe; Missa choralis (with organ); Missa and Requiem for male voices (with organ); Psalms, 13, 137, 23, and 18; 12 Kirchen-Chor-Gesänge (with organ). Cantatas: Prometheus-chöre; "Beethoven Cantata"; "An die Künstler"; Die Glocken des Strassburger Münsters; 12 Chöre für Männergesang; Songs, 8 books; Scena, Jeanne d'Arc au bûcher.

Melodramatic Pieces for Declamation, with Pianoforte Accompaniment.—Leonore (Bürger); Der traurige Mönch (Lenau); Des toden Dichter's Liebe (Jokai); Der blinde Sänger (Tolstoy).

Editions, Text and Variants.—Beethoven's Sonatas; Weber's Concertstück and Sonatas; Schubert Fantasia, 4 Sonatas, Impromptus, Valses, and Moments musicaux. (E. DA.)

Litchfield, a city of Montgomery county, Illinois, U.S.A., at the intersection of six railways and at an altitude of 664 feet. Its site is on the level prairie, its plan is regular, and it has Holly water-works and other municipal improvements. It is in a region of coal, natural gas, and petroleum. Population (1880), 4326; (1890), 5811; (1900), 5918, of whom 521 were foreign-born and 156 were negroes.

Lithgow, town, Australia, New South Wales, in the county of Cork, 96 miles west of Sydney by rail. Coal is found in the district, which has also ironworks, brick-works, and a large pottery. Altitude, 3000 feet. Population (1881), 2112; (1891), 3865; (1901), 5269.

Lithography. See ENGRAVING.

Litin, a district town of Russia, government of Podolia, on the Bug river, 67 miles south-south-west of Zhitomir, and 19 miles from Vinnitsa railway station. It is an old town, which existed under the name of Lytyn in the first half of the 15th century. It has brisk trade in grain, timber, and wooden goods. Population, 11,162.

Littleborough, a town in the Middleton parliamentary division of Lancashire, England, on the Rochdale canal, 3 miles north-east of Rochdale by rail. There are an endowed free school (founded 1727) and a technical institute. The industries are cotton and woollen manufactures and dyeing; in the neighbourhood there are

collieries and quarries. Area of urban district, 7736 acres. Population (1881), 10,406; (1891), 10,878; (1901), 11,166.

Little Falls, a city of Minnesota, U.S.A., capital of Morrison county, on the east bank of the Mississippi river, on the Northern Pacific railroad, at an altitude of 1117 feet. It has excellent water-power, which has been made use of in lumber manufacture, the principal industry of the city. Population (1880), 508; (1890), 2354; (1900), 5774, of whom 1559 were foreign-born.

Little Falls, a city of Herkimer county, New York, U.S.A., on the Mohawk river, the Erie canal, the New York Central and Hudson River, the West Shore, and the Little Falls and Dolgeville railways, at an altitude of 376 feet. It is irregularly built on a steep slope. The fine water-power furnished by the falls in the Mohawk river has been turned to account in a variety of manufactures. Population (1890), 8783; (1900), 10,381, of whom 1915 were foreign-born.

Littlehampton, a parish, town, and seaport in the Eastbourne parliamentary division of Sussex, England, at the mouth of the Arun, 59 miles south-south-west of London, with a station on the London, Brighton, and South Coast railway. The town is an attractive seaside resort. The church of St Mary the Virgin was reconstructed in 1899, and a chapel of ease (a wooden structure) was erected in 1877. The Roman Catholic church, built in 1864, was enlarged in 1884. There are Congregational, Methodist, and other places of worship. The town is provided with a public hall, excellent golf-links, and a field of 11 acres for sports, presented by the duke of Norfolk in 1897. The harbour is easily accessible in all weathers, and in 1900 was entered and cleared by an aggregate of 802 vessels of 65,650 tons, the trade being valued at about £53,000. Area of urban district, 2325 acres. Population (1891), 5772; (1901), 7363.

Little Rock, a city of Arkansas, U.S.A., capital of Pulaski county and of the state, of which it is the largest city, on the south bank of the Arkansas river, at the east base of the Ozark Hills, at an altitude of 263 feet. It has a level site, a regular plan with broad streets, a good water-supply and sewerage system, and is divided into eight wards. It is on the St Louis, Iron Mountains and Southern, the St Louis South-Western, the Choctaw and Memphis, and the Little Rock and Hot Springs Western railways, which, with steamboats on the river, give it a large trade. In 1890 its manufacturing establishments numbered 124, with a total capital of \$2,265,324. They employed 1534 hands, and their product was valued at \$3,120,677. The leading products were cotton-seed oil and oil-cake, valued at \$937,963, and lumber, valued at \$324,000. Little Rock is the seat of Philander Smith University, a Methodist Episcopal institution, founded in 1877. The assessed valuation of real and personal property in 1900, on a basis of about 40 per cent. of the full value, was \$14,845,458; the net debt of the city was only \$217,719, and the rate of taxation was \$22 per \$1000. Population (1890), 25,874; (1900), 38,307, of whom 2099 were foreign-born and 14,694 were negroes.

Littlestone-on-Sea. See ROMNEY, NEW.

Liverpool, a city, municipal, county, and parliamentary borough and seaport of Lancashire, England, 201 miles north-west of London by rail, on the right bank of the Mersey, about three miles from the open sea. The city extends about six miles along the east bank of the estuary, which here runs nearly north and south and is about one mile in breadth. On the north

the city is bounded by the borough of Bootle, along which the line of docks is continued, and on the south by the township of Garston. In 1891 the population was 517,980; in 1901 it had reached 686,332. The birth-rate for 1901 was 32.2, and the death-rate 21.6 per thousand. An extension of the city boundaries took place on 9th November 1895, when an estimated population of 134,234 and an area of 8026 acres of land and 2016 acres of water space were added. At the same time the number of the wards was increased to 28, and the number of aldermen to 28 and councillors to 84. In 1899 a fresh ward with 1 alderman and 3 councillors was added, a similar increase also taking place in 1900. The total area now stands at 15,252 acres, comprising 30 wards, with 30 aldermen and 90 councillors. In 1893 the title of mayor was raised to that of Lord Mayor. The rateable value in 1890 was £3,221,771; in 1895, £3,168,315; in 1900, £3,711,986. The decrease in 1895 was due to the demolition of a large quantity of insanitary property, while the marked increase in 1900 was largely due to the extension of the boundaries. In 1885 the number of members of Parliament was increased to nine by the creation of six new wards.

The following table gives particulars of the chief suburbs on the east side of the river:—

	Population, 1901.	Rateable Value.
Bootle (borough of)	58,556	£504,311
Allerton	1,100	24,296
Childwall	219	4,092
Garston	17,288	121,178
Great Crosby	7,555	45,000
Huyton-cum-Roby	4,661	31,456
Litherland	10,592	42,689
Little Crosby	563	5,358
Little Woolton	1,091	13,044
Much Woolton	4,731	24,352
Waterloo-cum-Seaforth	23,102	109,932

Since 1882 several of the city churchyards have been laid out in gardens. A playground containing 108 acres in Wavertree was presented in 1895 by an anonymous donor. The total area of the public parks and gardens now amounts to 772½ acres. In 1884 a new County Sessions House, adjoining the Walker Art Gallery opposite St George's Hall, was opened for public business. In 1889 a wholesale fish market in Great Charlotte Street was opened, and in 1896 the new Liverpool Cotton Exchange. In 1899 the new post office in Victoria Street was completed. Considerable alterations in the internal structure of the town hall have been made, and the council chamber is now extended so as to permit of the enlarged council meeting without discomfort, and provides seating accommodation for 124 members. The Shakespeare Theatre was opened in 1888. The Free Library has steadily increased in size and usefulness, and now contains upwards of 120,000 volumes in the reference department. There are nine lending libraries and reading-rooms under control of the central library, and in these the total number of volumes is nearly 92,000. The basement of the Brown Library (central reference) has been reconstructed to provide additional book space, to establish a special newspaper files and patent department, and to provide a central lending library.

The *Walker Art Gallery*, spacious though it was, as originally constructed, began to prove inadequate to meet the requirements of the recurring exhibitions and the housing of the steadily growing permanent collection very shortly after its opening in 1877, and a scheme was sanctioned by the council for the enlargement of the building to almost twice its original size by an addition on the north side. This improvement was completed and opened in 1884, the entire cost of the additions being borne by Sir Andrew Walker, Bart. The permanent collection now numbers upwards of 750 works, including sculpture. An important addition was made in 1894, when the examples of early Italian art, numbering altogether

about 180 pictures, collected at the beginning of the 19th century by William Roscoe, were deposited in the gallery. They had formerly been housed at the Royal Institution, Colquh Street.

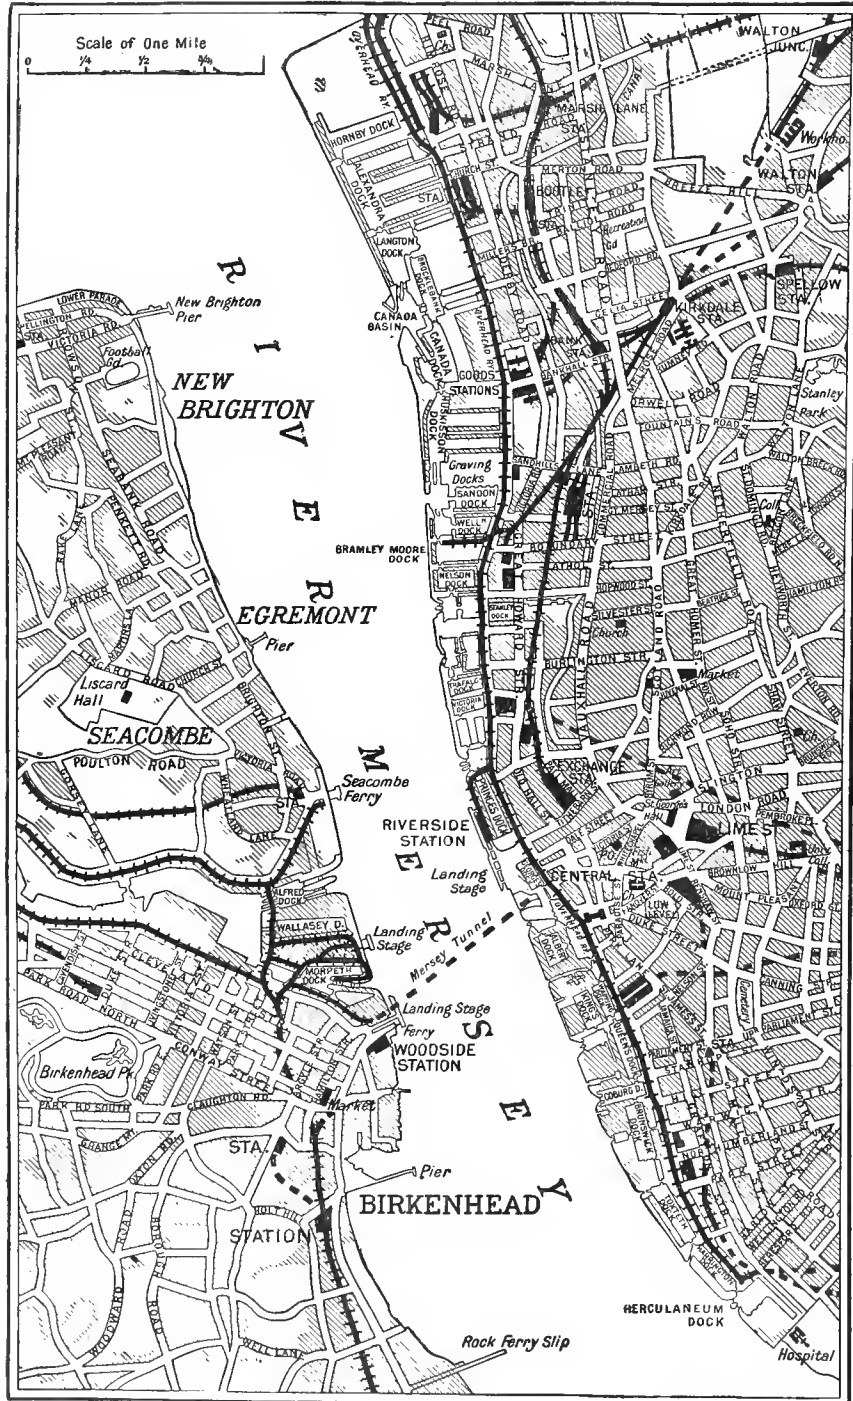

Museums.—Very extensive alterations in the structure and arrangement of the William Brown Museum have been undertaken. The ground on which the building stands falls somewhat sharply

school below the level of the museum, with an entrance from Byrom Street distinct from the museum entrance. The former levels in the museum are maintained, and the new galleries, which are extended in a westerly direction over the technical school, fit into the old, and together they form immense horse-shoe galleries, each about 500 feet long by 35 feet wide; and it is possible now to

arrange the magnificent collection in the possession of the Corporation logically and comprehensively, so that a regular sequence of ideas may be obtained. In addition to this, a fine series of laboratories for biological investigation has been constructed and fitted with all the latest appliances, in which original research may be carried on, in addition to the usual dissection for museum exhibits and the ordinary mounting of specimens.

Municipal Technical Schools.—The building for the Central Municipal Technical School in Byrom Street, the upper part of which, as stated above, is devoted to museum galleries, was opened in October 1901, the cost of the building, exclusive of the site and equipment, being over £112,000. The Nautical College established by the Corporation in 1892 is now carried on in this building, which comprises a small astronomical observatory in addition to the usual lecture rooms, laboratories, and workshops. The Corporation have also built two branch technical schools in the north and east districts of the city, and conduct classes also in other buildings which have been adapted for the purpose in the other districts.

Colleges and Schools.—University College received its charter of incorporation on the 18th October 1881, and on the 15th November 1884 was admitted as a college of the Victoria University. Since its foundation a sum of upwards of £500,000 has been raised by voluntary contribution, in addition to £33,708 contributed by public bodies. Twenty-seven chairs have been endowed, and the university buildings very largely extended. There are at present 24 professors and 24 lecturers. The average attendance of students in 1899–1900 amounted to 409 in the arts and science and 154 in the medical school. The number of students attending evening classes amounted to 717. Early in 1900 a supplemental charter extended the powers of self-government, and brought the college into close relations with the authorities of the city and with local institutions, by providing for their fuller representation on the court of governors. The authorities of the college are the president, the vice-presidents, the court of governors, the council, the treasurer, and the senate. The general management is conducted by the council, which is composed of the president, the vice-presidents, the treasurer, the principal and three professors of the college chosen by the senate, fifteen persons chosen by the court of governors, and three persons chosen by the municipal council. The School Board was introduced in 1870, and the first Board elected on the 25th November in that year. At that time the number of scholars under the Board (average

PLAN OF LIVERPOOL.

attendance) amounted to 47,590, and the number of schools to 80. The figures for the month of June 1901 were as follows:—32 permanent and 18 temporary board schools, and 108 voluntary schools, with an average attendance at the former of 41,855 and at the latter of 64,440. During the year ending 30th June 1901 the municipal expenditure was £128,000, while the various Government grants amounted to £71,669.

Churches.—The various denominations have nearly all seen an

in a westerly direction, and the Corporation have extended the galleries previously in existence by building an addition at the west end equal in size to the whole of the previous museum and library building as presented by Sir William Brown. By excavating the slope from a face perpendicular to the west wall of the old museum down to the level of Byrom Street (a thoroughfare running north and south some fifty yards away at the foot of the slope), accommodation has been found for a large central technical

increase in the number of churches attached to them. The numbers now stand approximately as follows:—Established Church, 103; Roman Catholic, 34; Welsh Nonconformists, 29; Wesleyan, 25; Presbyterian, 22; Methodists, 21; Baptist, 17; Congregational, 13; Unitarians, 5; others, 25. None of the new churches call for any special notice.

Railways.—A new railway route to Southport *via* the Cheshire lines was opened for traffic in 1884, and the Mersey Tunnel, connecting Birkenhead with Liverpool, in 1885. The Exchange Station in Tithebarn Street, which was formerly approached by a long flight of steps, was brought down to the level of the street and opened for passenger traffic in 1896. An extension of the Mersey railway, bringing Wallasey, Hoylake, and New Brighton into direct communication with Liverpool, was completed in 1888. The Electric Overhead railway, running along the line of docks from Seaford to the Dingle, was formally opened in 1893. In 1895 the riverside station at the Princes Dock was completed, giving direct access from the landing-stage to the London and North-Western system.

Tramways.—The Corporation in 1896 purchased the property, rights, powers, and privileges of the Liverpool Electric Supply Company, and in the following year the undertaking of the Liverpool Tramway Company, which they formally took over in the autumn of the same year. Since that date a large and extended system of electric tramways has been laid down, which has led to a very remarkable increase in the receipts and the number of passengers carried. The following table shows how rapidly the tramways have spread during 1897–1901:—

Year.	Passengers.	Miles run.	Receipts.
1897	38,400,084	6,013,182	£290,743
1898	41,772,034	6,279,758	314,207
1899	63,771,450	7,600,546	359,929
1900	82,367,958	9,100,866	417,574
1901	101,108,780	10,970,063	468,383

The mileage under the electric system is 95 miles of single track.

Lighting.—A steady improvement in lighting has taken place, especially since the Corporation took it over in 1894. The following comparative table of the old city area will show this more clearly:—

Year.	No. of Lamps.	Mileage.	Courts.	Passage Lamps.	Candle-power.	Cost.
1890	11,330	272	1761	...	744½ millions	£39,000
1901	11,905	275	1084	1045	2261 ,,	31,187

The second table shows the improvement in the extended area added to the city in 1895:—

Year.	No. of Lamps.	Mileage.	Candle-power.	Cost.
1895	2789	128	137½ millions	£7194
1901	3493	144	623 ,,	7900

The increased candle-power and decreased cost have been mainly brought about by the introduction of a system of incandescent gas burners. Electric light is also used in many of the main thoroughfares, and has been installed in all the principal shops and many of the better-class dwelling-houses.

	1885.		1895.		1900.

Entered—						
Liverpool	14,018	7,070,245	19,457	8,675,049	20,300	9,815,674
Manchester	1,752	589,159	2,900	1,230,784

It is the docks, however, that indicate the growth and extent of Liverpool's trade (see Docks). In September 1881 the opening of the newly-completed Langton and Alexandra Docks at the extreme north end of the river frontage indicated a substantial advance towards the completion of the great scheme of dock extension for which parliamentary powers had been obtained in 1873. That scheme may be said to have been fully completed in 1889, the Hornby Dock at the north end, and the Harrington, Toxteth, and Union Docks at the south end, bringing up the water area of the docks at Liverpool, which in 1882 was 343 acres, to 380 acres in 1889 (not including Birkenhead). Since the latter date the advances which the port has made in the matter of dock accommodation are not to be measured so much by the figures of water area and quays, although these have both increased, but by the augmented depths of docks, entrances, water approaches, and the increased width of entrances, improvements in the alignment of the quays, in the class of sheds provided on them for the accommodation of goods, and in the facilities for handling ships and goods generally. Thus in 1889 an important scheme of improve-

Water Supply.—The Rivington reservoirs in Lancashire (8 in number), with a total capacity of 4,105,000,000 gallons, continue to supply Liverpool with water, supplemented by several of the old wells bored in the pebble beds of the New Red Sandstone. The main supply, however, is drawn from Lake Vyrnwy in Montgomeryshire and Rivington. The scheme for utilizing the water from the Vyrnwy district was adopted by the City Council in 1879, and the necessary powers obtained in the following year. The works were begun in 1881, and completed eleven years later. The impounding of the water was commenced on the 28th of November 1888, and the overflow was not reached until the 25th of November 1889, the process of filling, therefore, occupying almost twelve months. A temporary supply was obtained from Lake Vyrnwy in July 1891, as it was urgently needed, and the permanent aqueduct was completed shortly afterwards. The total area of the gathering-grounds of Rivington and Vyrnwy from which the Corporation can impound water is 32,742 acres. (See WATER-SUPPLY AND AQUEDUCTS.) The consumption of water per head of the population has gradually increased, the figures being—1846, 8.24 gallons per head; 1881, 24.84; 1891, 25.25; 1901, 30.62.

Trade and Shipping.—Though Liverpool is essentially a port, and the main industries are those dependent on shipping, several other forms of industrial enterprise have made rapid strides during the period. The confectionery trade is a case in point, several large works having been built, no doubt induced by the prospect of cheap sugar directly from the Liverpool quays. The cutting, blending, and preparing of crude tobacco have also led to the erection of several large factories employing several thousands of hands. Two large mills, fitted with the latest and most improved machinery for expressing oil from various oleaginous seeds and for the production of feeding cake for cattle, have also added to the general prosperity. One of these latter has grown from the employment of only a few hands to that of nearly a thousand, and the works now rank among the largest in the world for this class of business. As will be seen from the figures given below, the general trade of the port has steadily grown. The figures for the port of Manchester have been introduced as they are important for the sake of comparison, representing trade which has passed through Liverpool.

Exports of Produce and Manufacture of United Kingdom.

	1885.	1895.	1900.
Liverpool	£79,765,100	£78,126,746	£87,488,183

Cleared—						
Liverpool	12,965	6,624,272	19,261	8,525,185	19,620	9,158,332
Manchester	1,509	636,305	2,926	1,249,468

ment at the Canada and Huskisson Docks was commenced, which comprised the alteration of the Canada Dock and lock, the construction of a new branch dock of about 7½ acres area, with sheds of the newest type, and a large new graving dock capable of receiving the very largest steamer. This graving dock is 925½ feet long, 94 feet wide at entrance, and has 34 feet depth of water on its sill on spring tides. In addition to the works above mentioned, the scheme comprised deepening and other improvements at Huskisson Dock, and the provision of a large new half-tide dock on the site of Sandon Basin and Wellington half-tide dock. Within a few years of their deciding to improve the Canada-Huskisson system, so great and rapid was the development of shipping that the Mersey Docks and Harbour Board found that the alterations provided by the scheme of 1891 would be quite inadequate, and in 1898 they sought and obtained powers to supplement it by large additions at the north and south ends of their estate. Under these powers the Sandon graving docks are being obliterated and a new branch dock constructed, and the construction of another large graving dock is contemplated. The scheme of 1898 also provides for a

reconstruction in a deepened and otherwise improved form of the whole of the Queen's-Wapping group of docks, and the provision of deep-water approaches thereto by means of new river entrances at Brunswick Dock, deepening of Brunswick Dock and the passage between it and the Queen's Dock. Four new branch docks and two graving docks were provided for. In 1895 a great improvement was made in the facilities for passenger traffic by the construction of a railway station on the river side of the Princes Dock, and the extension of railway lines from the London and North-Western Railway Company's trunk and other systems to that point, so that passengers disembarking from Atlantic liners at the landing-stage could enter trains at once and proceed to their destinations. The landing-stage was extended to 2460 feet in length. A very fine group of wool warehouses was constructed on the east side of Great Howard Street, and was opened in 1896. A block of warehouses, having fourteen floors in all and a total floor area of 36 acres, has been constructed for the storage of tobacco, the stock of which in the port is about 100,000 hogsheads, and such a stock can be accommodated in the group of warehouses at the Stanley Dock, consisting of the new warehouse above referred to and the old warehouses. A large part of the George's Dock has been sold to the Corporation; on the other hand, about twelve acres of land hitherto in the hands of the Manchester Ship Canal Company, owners of the Duke's Dock property, has been acquired by the Board. No account of the port would be complete without mention being made of the unique dredging operations (see DREDGING) which have taken place at the bar of the Queen's Channel, which have enabled the largest ocean liners to enter the river at all hours, except upon the rarest occasions. The dredging at the bar was commenced as an experiment in September 1890 by two of the Board's ordinary hopper barges of 500 tons capacity each. The result was favourable, and in 1892 the Board decided to order a new hopper dredger larger than any hitherto built. This vessel, which cost about £60,000, was set to work in July 1893. Then another vessel of like size was built, and in November 1895 put to work on the bar; and as the result of all these operations, up to the 17th November 1900 there had been removed over 25,773,000 tons of sand. Before dredging was commenced the depth of water at dead low water of spring tides was only 11 feet; now there is, under the same conditions, about 27 feet. The space over which dredging has been carried on at the bar measures about 7000 feet by 1250 feet wide, the latter being the average width of the buoyed cut or channel through the bar. Dredging has also taken place on shoals and projections of sand-banks in the main sea channels, and from these the sand pump dredgers have removed over 26,085,500 tons. The total expenditure in connexion with the dredging operations up to the 1st of July 1900, not including capital cost of plant, interest, or depreciation on capital, was about £192,283. The expenditure in like terms for the year ending the 1st July 1900 was £24,400. (W. F. I.)

Liversedge, a township, urban district, and railway station in the Spen Valley parliamentary division of Yorkshire, England, 3 miles north-west of Dewsbury. The industries are chiefly the manufacture of woollen goods, the making of machinery, chemical manufactures, and coal mining. Area, 2130 acres. Population (1881), 12,757; (1901), 13,978.

Livingstone (or **KINGA**) **Mountains**, a band of highlands in German East Africa, forming the eastern border of the rift valley of Lake Nyasa, at the northern end of the lake. In parts these highlands present rather the character of a plateau than of a true mountain range, but the latter name may be justified by the fact that they form a comparatively narrow belt of country, which falls considerably to the east as well as to the west. The northern end is well marked in 8° 50' S. by an escarpment falling to the Ruaha valley, which is regarded as a north-eastern branch of the main rift valley. Southwards the Livingstone range may be considered to terminate in the deep valley of the Ruhuhu in 10° 30' S., the first decided break in the highlands that is reached from the north, on the east coast of Nyasa. Geologically the range is formed on the side of the lake by a zone of gneiss running in a series of ridges and valleys generally parallel to its axis. The ridge nearest the lake (which in Mount Chamembe, 9° 41' S., rises to an absolute height of 7870 feet, or 6200 feet above Nyasa) falls almost sheer to the water, the same steep slope being continued beneath the surface. Towards the south the range appears to have a

width of some 20 miles only, but northwards it widens out to about 40 miles, though broken here by the depression, drained towards the Ruaha, of Buanyi, on the south side of which is the highest known summit of the range, reaching a height of 9600 feet. North and east of Buanyi, as in the eastern half of the range generally, table-topped mountains occur, composed above of horizontally bedded quartzites, sandstones, and conglomerates. The uplands are generally clothed in rich grass, forest occurring principally in the hollows, while the slopes towards the lake are covered with poor scrub. Native settlements are scattered over the whole range, and German mission stations have been established at Bulongwa and Mtandala, a little north of the north end of Nyasa, at the former of which European crops have been cultivated with success. The climate is here healthy, and night frosts occur in the cold season.

See BORNHARDT in *Verh. Gesells. Erdk.*, Berlin, 1899, No. 10. (E. HE.)

Livonia, or **LIVLAND** (*Liflandia* of the Russians), one of the three Baltic provinces of Russia. Its area, with the islands, but without Lake Peipus, covers 17,070 square miles. The population in 1897 was 1,300,640 (as against 1,121,000 in 1882), out of whom 670,038 were women, and 376,040 lived in towns. In 1895, out of a total population of 1,274,531, the peasants numbered 1,146,658; artisans, 98,366; noblemen, 8275; clergy, 3135; merchants, 5898; foreigners, 10,317; and various, 1882; to which 36,147 military had to be added. The bulk of the population consisted of Letts (552,860) and Esthonians (509,243), Germans, Russians, Jews, and Poles coming next in the order named.

Agriculture has reached a high degree of perfection, especially on the estates of the landlords. The fields are drained, and no fewer than 300 artesian wells are used for irrigation; 41 per cent. of the total surface is under artificial meadows and pastures, including dried-up marshes. Dairy-farming has been rapidly growing, and factories for the utilization of raw produce, derived from improved cattle-rearing, have been on the increase. The average crops of the years 1895-99 were: rye, 4,775,000 cwt.; wheat, 360,000; oats, 3,926,000; barley, 4,188,000; all cereals, 13,566,000 cwt. Gardening is on the increase. Fishing in Lake Peipus gives occupation to nearly 100,000 persons. The industries are rapidly developing, the aggregate yearly returns of the factories reaching £8,824,000 in 1897. Woollen, cloth, cotton, and flax mills, steam flour and saw mills, distilleries and breweries, machinery works, paper mills, furniture, tobacco, soap, candle, and hardware works are among the chief industrial establishments. Education stands on a much higher level than elsewhere in Russia, no less than 87 per cent. of the children receiving regular education. Of higher educational institutions there are Dorpat University, Riga polytechnicum, and a high school for the clergy. There are also 16 gymnasia for boys, and 11 high schools for girls, and a considerable number of general and professional schools. The government is divided into eleven districts, the chief towns of which, and their population in 1897, are:—Riga, capital of the government (256,197, as against 104,200 in 1881); Arensburg, in the island of Oesel (4621); Dorpat, now named officially Yuriev (42,421); Fellin (7659); Längsall (2425); Pernau (12,856); Schlock (2011); Walk (10,139); Wenden (6327); Werro (4154); and Wolmar (5112). (P. A. K.)

Llandrindod Wells, a health resort of Wales, near the middle of Radnorshire, situated amid somewhat bare surroundings, 46 miles by rail west-north-west of Hereford. Its medicinal waters—chalybeate, sulphurous, and saline—attract some thousands of visitors annually, and the place is equipped with three pump-houses, a public hall, golf-course, park, and electric light. The waters have been long known, and were visited in the 18th century. Population (1901), 1827.

Llandudno, a parish and favourite seaside resort in the Arfon parliamentary division of Carnarvonshire, Wales, 227 miles north-west of London by rail. There are several public halls, two theatres, two hospitals, a library,

and hydropathic establishments, and a new town hall and assembly rooms were opened in February 1902. The pier is 1250 feet long. Area of urban district, 3034 acres. Population (1881), 4807; (1891), 7348; (1901), 9307.

Llanelly, a seaport of Carmarthenshire, Wales, 10 miles west-north-west of Swansea by rail. It unites with Carmarthen to send one member to Parliament. Modern erections include a new town hall, a hospital, a higher-grade school, a theatre, and a parish hall. There is an intermediate and technical college. In 1888, 1228 vessels of 167,646 tons entered, and 1233 of 168,864 tons cleared; in 1898, 1068 vessels of 181,288 tons entered, and 1665 vessels of 181,211 tons cleared. Area of the urban district, 2107 acres. Population (1891), 21,360; (1901), 24,213.

Llanes, a picturesque coast town of northern Spain, in the province of Oviedo, on the river Carrocedo. The population in 1897 was 19,224. The streets are mostly narrow and irregular, and contain some curious and interesting old houses. The parish church is a fine Gothic structure. The old Augustine convent has been turned into a school, with gymnasium, meteorological station, adult and commercial classes, and a library. The district is much frequented in summer. Llanes is a second-class port for light-draught vessels; but the entrance is narrow, and rather difficult in rough weather. The trade is chiefly in agricultural products, timber, butter, and fish.

Llerena, a town and railway station of Spain, in the province of Badajoz, near the Seville frontier. The population was 6181 in 1897. Remains of the old walls and towers still survive. The local markets are important. The surrounding districts produce wheat, chick-peas, wine, oil; and live stock is extensively reared. The local industries are chiefly the manufactures of soap, linen, and coarse woollen stuffs.

Lloyd, Edward (1845—), English tenor, was born in London, 7th March 1845, his father, Richard Lloyd, being vicar choralist at Westminster Abbey. From 1852 to 1860 he sang in the Abbey choir, and was thoroughly trained in music, eventually becoming solo tenor at the Chapel-Royal. He began singing at concerts in 1867, and in 1871 appeared at the Gloucester Musical Festival. His fine evenly-produced voice and pure style at once brought him into notice, and he gradually took the place of Sims Reeves as the leading English tenor of the day, his singing of classical music, and especially of Handel, being particularly admired. At the Handel Festivals after 1888 he was the principal tenor, and even in the vast auditorium at the Crystal Palace his silver-trumpet tones triumphed over acoustic difficulties. In 1888, 1890, and 1892 he paid successful visits to the United States; but by degrees he appeared less frequently in public, and in 1900 he formally retired from the platform.

Lloyd's. See INSURANCE.

Loanda, or SÃO PAULO DE LOANDA, a city and episcopal see of Portuguese West-Africa, capital of the province of Angola, situated on a bay between the rivers Bengo and Quanza. It is a good port, with a floating dock, and possesses a meteorological observatory, hospital, public garden, tramways, gas-works, statues to Salvador Correia de Sá, who wrested the colony from the Dutch, and to Pedro Alexandrino, a former governor, and is the terminus of the railway (190 miles) inland to Ambaca. The district of LOANDA stretches along the Atlantic from the river Loge to the Tapado, and has a population of

190,867, exclusive of Libollo and Songo. The trade reaches an annual value of 1¼ millions sterling, as compared with less than half a million sterling in 1888.

Lobánof-Rostofski, Alexis Borisovitch, PRINCE (1824–1896), Russian statesman, was born on 30th December 1824, and educated, like Prince Gortchakoff and so many other eminent Russians, at the lyceum of Tsarskoe Selo. At the age of twenty he entered the diplomatic service, and rose in the usual way till he became Minister at Constantinople in 1859. In 1863 a regrettable incident in his private life made him retire temporarily from the public service, but four years later he re-entered it and served for ten years as *adlatus* to the Minister of the Interior. At the close of the Russo-Turkish war in 1878 he was selected by the emperor to fill the post of ambassador at Constantinople, and for more than a year he carried out with great ability the policy of his Government, which aimed at re-establishing tranquillity in the Eastern Question, after the volcanic disturbances produced by the reckless action of his predecessor, Count Ignatief. In 1879 he was transferred to London, and in 1882 to Vienna; and in March 1895 he was appointed Minister of Foreign Affairs in succession to M. de Giers. In this important position he displayed much of the caution of his predecessor, but adopted a more energetic policy in European affairs generally and especially in the Balkan Peninsula. At the time of his appointment the attitude of the Russian Government towards the Slav nationalities had been for several years one of extreme reserve, and he had seemed as ambassador to sympathize with this attitude. But as soon as he became Minister of Foreign Affairs, Russian influence in the Balkan Peninsula suddenly revived. Servia received financial assistance; a large consignment of arms was sent openly from St Petersburg to the prince of Montenegro; Prince Ferdinand of Bulgaria became ostensibly reconciled with the Tsar, and his son Boris was received into the Eastern Orthodox Church; the Russian embassy at Constantinople tried to bring about a reconciliation between the Bulgarian Exarch and the Œcumenical Patriarch; Bulgarians and Servians professed, at the bidding of Russia, to lay aside their mutual hostility. All this seemed to foreshadow the creation of a Balkan confederation hostile to Turkey, and the Sultan had reason to feel alarmed. In reality Prince Lobánof was merely trying to establish a strong Russian hegemony among these nationalities, and he had not the slightest intention of provoking a new crisis in the Eastern Question so long as the general European situation did not afford Russia a convenient opportunity for solving it in her own interest without serious intervention from other Powers. Meanwhile he considered that the integrity and independence of the Ottoman Empire must be maintained so far as these other Powers were concerned. Accordingly, when Lord Salisbury proposed energetic action to protect the Armenians, the Cabinet of St Petersburg suddenly assumed the rôle of protector of the Sultan, and vetoed the proposal. At the same time efforts were made to weaken the Triple Alliance, the principal instrument employed being the *entente* with France, which Prince Lobánof helped to convert into a formal alliance between the two Powers. In the Far East he was not less active, and became the protector of China in the same sense as he had shown himself the protector of Turkey. Japan was compelled to give up her conquests on the Chinese mainland, so as not to interfere with the future action of Russia in Manchuria, and the financial and other schemes for increasing Russian influence in that part of the world were vigorously supported. Strange to say, all this activity, though combined with a haughty tone towards foreign Governments and diplomatists, did not produce

much general apprehension, probably because there was a widespread conviction that he desired to maintain peace, and that his great ability and strength of character would enable him to control the dangerous forces which he boldly set in motion. However this may be, before he had time to mature his schemes, and when he had been the director of Russian policy for only eighteen months, he died suddenly of heart disease when travelling with the emperor on 30th August 1896. Personally Prince Lobanof was a *grand seigneur* of the Russian type, proud of being descended from the independent princes of Rostof, and at the same time an amiable man of wide culture, deeply versed in Russian history and genealogy, and perhaps the first authority of his time in all that related to the reign of the Emperor Paul.

(D. M. W.)

Lobatchewsky, Nicolas Ivanovitch (1793–1856), Russian mathematician, was born at Makarief, Nijni-Novgorod, in 1793. His father died about 1800, and his mother, who was left in very poor circumstances, removed to Kazañ with her three sons, who went to school at the gymnasium of that town. In 1807 Nicolas, the second boy, entered as a student in the University of Kazañ, then recently established. Five years later, having completed the curriculum, he began to take part in the teaching, becoming assistant professor in 1814 and extraordinary professor two years afterwards. In 1823 he succeeded to the ordinary professorship of mathematics, and retained the chair until about 1846, when he seems to have fallen into official disfavour. At that time his connexion with the university to which he had devoted his life practically came to an end, except that in 1855, at the celebration of its jubilee, he brought it as a last tribute his *Pangéométrie*, in which he summarized the results of his geometrical studies. He died on 24th February (N.S.) 1856. Lobatchewsky's fame has probably become much greater since his death than ever it was in his lifetime. He was one of the first thinkers to apply a critical treatment to the fundamental principles of geometry, which, as laid down by Euclid, had been accepted almost without question for two thousand years, and he thus became a pioneer of that modern geometry which deals with space other than as defined by Euclid's postulates. His first contribution to the theory of hyper-geometry is believed to have been given in a lecture at Kazañ in 1826, but the subject is treated in many of his subsequent memoirs, among which may be mentioned the *Geometrische Untersuchungen zur Theorie der Parallellinien* (Berlin, 1840), and the *Pangéométrie* already referred to, which in the sub-title is described as a précis of geometry founded on a general and rigorous theory of parallels. (See GEOMETRY, NON-EUCLIDEAN.) In addition to his geometrical studies, he made various contributions to other branches of mathematical science, among them being an elaborate treatise on algebra (Kazañ, 1834). Besides being a geometer of power and originality, Lobatchewsky possessed the gift, not vouchsafed to every great mathematician, of being an excellent man of business. Under his administration the University of Kazañ prospered as it had never done before; and he not only organized the teaching staff to a high degree of efficiency, but arranged and enriched its library, furnished instruments for its observatory, collected specimens for its museums, and provided it with proper buildings. In order to be able to supervise the erection of the last, he studied architecture, with such effect, it is said, that he was able to carry out the plans at a cost considerably below the original estimates.

Löbau, a town of Germany, on the Löbau water, 12 miles south-east of the town and in the circle of Bautzen, kingdom of Saxony, on the Dresden-Görlitz railway, with

lines to Oberoderwitz and Ebersbach. There are three Protestant churches, one Catholic church, a seminary for teachers, a *real*, a commercial, and a burgher school. It has dye, agricultural implement, pianoforte, and button works, and a considerable trade in grain, yarns, linens, and stockings. Population (1890), 7523; (1900), 9627.

Lob-nor, or LOP-NOR, a lake of Central Asia, in the Gobi Desert, between the Altyn Tagh on the south and the Kurruk Tagh on the north. Previous to 1876 it was placed in nearly all maps at 42° 30' N., a position which agreed with the accounts of ancient Chinese geographers. In the year mentioned the Russian Prjevalsky discovered two closely connected lake-basins, Kara-Buran and Kara-Koshun, fully one degree farther south, and considerably to the east of the site of the old Lop-nor, which lake-basins he nevertheless regarded as being identical with the old Lop-nor of the Chinese. But the water they contained he pronounced to be fresh water. This identification was disputed by baron von Richthofen, on the ground that the Lop-nor, the "Salt Lakes" of the Chinese geographers, could not be filled with fresh water; moreover, being the gathering basin of the desert stream the Tarim, it was bound to be salt, more especially as the lake had no outflow. Prjevalsky visited the Lop-nor region again in 1885, and adhered to his opinion. But ten years later it was explored anew by Dr Sven Hedin, the Swedish traveller, who ascertained that the Tarim empties part of its waters into another lake, or rather string of lakes (Avullu-köll, Kara-köll, Tayek-köll, and Arka-köll), which are situated in 42° 30' N., and thus so far justified the views of von Richthofen, and confirmed the Chinese accounts. At the same time he advanced reasons for believing that Prjevalsky's lake-basins, the southern Lop-nor, are of quite recent origin—indeed, he fixed upon the year 1720 as the date of their formation. Besides this, he argued that there exists a close interrelation between the northern Lop-nor lakes and the southern Lop-nor lakes, so that as the water in the one group increases, it decreases to the same proportion and volume in the other. He also argued that the four lakes of northern Lop-nor are slowly moving westwards under the incessant impetus of wind and sandstorm (*buran*). These conclusions were afterwards controverted by the Russian geographer, M. Kozloff, who visited the Lop-nor region in 1893–94—that is, before Dr Sven Hedin's examination. Finally, in 1900 the Swedish explorer, following up the course of the Kum-daria, discovered at the foot of Kurruk Tagh the basin of a desiccated salt lake, which he holds to be the true Lop-nor of the Chinese geographers; and at the same time he found that the Kara-Koshun or Lop-nor of Prjevalsky had extended towards the north, but shrunk in the south. Thus the old Lop-nor no longer exists, but in place of it there are a number of much smaller lakes of newer formation. From all this it may fairly be inferred that, owing to the uniform level of the region, the sluggish flow of the Tarim, its tendency to divide and reunite, conjoined with the violence of the winds (mostly from the east and north-east), and the rapid and dense growth of the reed-beds in the shallow marshes, the drainage waters of the Tarim basin gather now in greater volume in one depression, and now in greater volume in another; and this view derives support from the extreme shallowness of the lakes in both Dr Sven Hedin's northern Lop-nor and Prjevalsky's southern Lop-nor.

See the accounts (in Russian) of Prjevalsky's first (1876–77) and second (1885) journeys.—VON RICHTHOFFEN. "Bemerkungen zu den Ergebnissen von Oberst-Lieutenant Prjewalskis Reise nach dem Lop-nor," in *Verhandl. der Gesch. f. Erdkunde zu Berlin*, 1878, pp. 121 et seq.—SVEN HEDIN. *Through Asia* (London, 1898), vol. i, pp. 15 et seq., and vol. ii, pp. 864 et seq. (J. T. BE.)

LOCAL GOVERNMENT (ENGLAND AND WALES).

LOCAL Government may be defined as the government of a local area as distinguished from the kingdom at large. It is that part of the government of the State which the supreme legislature has thought fit to delegate to local authorities or bodies, and it is therefore restricted not merely in respect of area, but in respect of the character and extent of the powers and duties entrusted to the local body. The system of local government now existing in England may be said to have been founded in 1888, when the Local Government Act of that year was passed. Since then the entire system of the government of districts and parishes has been reorganized with due regard to the preceding legislation. The largest area of local government is the county; next to that the sanitary district, urban or rural, including under this head municipal boroughs, all of which are urban districts. The parish is, speaking generally, the smallest area, though, as will hereafter be seen, part of a parish may be a separate area for certain purposes; and there may be united districts or parishes for certain purposes. It will be convenient to follow this order in the present article. But before doing so, it should be pointed out that all local bodies in England are to some extent subject to the control of central authorities, such as the Privy Council, the Home Office, the Board of Agriculture, the Board of Trade, the Board of Education, or the Local Government Board.

The subject of the Poor Law is separately treated, and the functions and duties of the Local Government Board as the successors of the Poor Law Board need not here be referred to. In 1848, pursuant to the Public Health Act of that year, the General Board of Health was established, and it continued in existence until 1854, when it was reconstituted. The existence of the new board, which was originally limited to one year, was extended from year to year until 1858, when it was allowed to expire, its powers under the various Acts for the prevention of diseases being transferred to the Privy Council, while those which related to the control of local authorities passed to the Secretary of State for the Home Department, to whose department the staff of officers and clerks formerly under the General Board of Health was transferred. This state of affairs continued until 1871, when the Local Government Board was constituted. It consists of a president appointed by His Majesty, and of the following *ex-officio* members: the president of the Privy Council, all the principal Secretaries of State for the time being, the Lord Privy Seal, and the Chancellor of the Exchequer. The board, as thus constituted, has power to appoint such secretaries, assistant-secretaries, inspectors, auditors, clerks, messengers, and other officers, as they may with the sanction of the Treasury determine. The president and one of the secretaries may sit in Parliament. To the board were transferred all the powers of the Secretary of State under the Public Health Act, 1848, and the numerous Acts relating to sanitary matters and the government of sanitary districts which had passed subsequently; together with all the powers and duties of the Privy Council under the Acts relating to the prevention of epidemic disease and to vaccination. Its powers and duties have been largely added to by subsequent legislation. A mere enumeration of them would be profitless. In so far as they affect local authorities, they will be mentioned hereafter under various heads.

The Administrative County.—For purposes of local government the geographical and the administrative county are generally the same. But this is not always the case. Thus each of the three Ridings of Yorkshire is an administrative county, as also is each of the three divisions of Lincolnshire, the eastern and western divisions of Sussex, the eastern and western divisions of Suffolk, the Isle of Ely and the residue of the county of Cambridge, the Soke of Peterborough and the rest of the county of Northampton. The metropolis forms the county of London. The administrative county includes all places within its area, with

two important exceptions. The first of these consists of the county borough. The second is the quarter sessions borough, which forms part of the county for certain specified purposes only. But the county includes all other places, such as liberties and franchises, which before 1888 were exempt from contribution to county rate. For each administrative county a county council is elected. For purposes of election the entire county is divided into divisions corresponding to the wards of a municipal borough, and one councillor is elected for each electoral division.

The electors are the county electors, *i.e.*, in a borough the persons enrolled as burgesses, and in the rest of the county the persons who are registered as county electors, *i.e.*, those persons who possess in a county the same qualification as burgesses must have in a borough, and are registered.

County council elections.

The qualification of a burgess or county elector is substantially the occupation of rated property within the borough or county, residence during a qualifying period of twelve months within the borough or county, and payment of rates for the qualifying property. A person so qualified is entitled to be enrolled as a burgess, or registered as a county elector (as the case may be), unless he is alien, has during the qualifying period received union or parochial relief or other alms, or is disentitled under some Act of Parliament such as the Corrupt Practices Act, the Felony Act, &c. The lists of burgesses and county electors are prepared annually by the overseers of each parish in the borough or county, and are revised by the revising barrister at courts holden by him for the purpose in September or October of each year. When revised they are sent to the town clerk of the borough, or to the clerk of the peace of the county, as the case may be, by whom they are printed. The lists are conclusive of the right to vote at an election, although on election petition involving a scrutiny the vote of a person disqualified by law may be struck off, notwithstanding the inclusion of his name in a list of voters.

The qualification of a county councillor is similar to that required of a councillor in a municipal borough, with some modifications. A person may be qualified in any one of the following ways: *viz.*, by being (1) enrolled as a county elector, and possessed of a property qualification consisting of the possession of real or personal property to the amount of £1000 in a county having four or more divisions, or of £500 in any other county, or the being rated to the poor rate on an annual value of £30 in a county having four or more divisions, or of £15 in any other county; (2) enrolled in the non-resident list, and possessed of the same property qualification (the non-resident list contains the names of persons who are qualified for enrolment in all respects save residence in the county or within seven miles thereof, and are actually resident beyond the seven miles and within fifteen miles); (3) entitled to elect to the office of county councillor (for this qualification no property qualification is required, but the office of a councillor elected on this qualification only becomes vacant if for six months he ceases to reside within the county); (4) a peer owning property in the county; (5) registered as a parliamentary voter in respect of the ownership of property in the county. Clerks in holy orders and ministers of religion are not disqualified as they are for being borough councillors, but in other respects the persons disqualified to be elected for a county are the same as those disqualified to be elected for a borough. Such disqualifications include the holding of any office or place of profit under the council other than the office of chairman, and the being concerned or interested in any contract or employment with, by, or on behalf of the council.

County councillors are elected for a term of three years, and at the end of that time they retire together. The ordinary day of election is the 8th March, or some day between the 1st and 8th March fixed by the council. Candidates are nominated in writing by a nomination paper signed by a proposer and seconder, and subscribed by eight other assenting county electors of the division; and in the event of there being more valid nominations than vacancies, a poll has to be taken in the manner prescribed by the Ballot Act, 1872. Corrupt and illegal practices at the election are forbidden by a statute passed in the year 1894, which imposes heavy penalties and disqualifications for the offences which it creates. These offences include not only treating, undue influence, bribery and personation, but certain others, of which the following are the chief:—Payment on account of the conveyance of electors to or from the poll; payment for any committee room in excess of a prescribed number; the incurring of expenses in and about the

election beyond a certain maximum; employing, for the conveyance of electors to or from the poll, hackney carriages or carriages kept for hire; payments for bands, flags, cockades, &c.; employing for payment persons at the election beyond the prescribed number; printing and publishing bills, placards, or posters which do not disclose the name and address of the printer or publisher; using as committee rooms or for meetings any licensed premises, or any premises where food or drink is ordinarily sold for consumption on the premises, or any club premises where intoxicating liquor is supplied to members. In the event of an illegal practice, payment, employment, or hiring, committed or done inadvertently, relief may be given by the High Court, or by an Election Court, if the validity of the election is questioned on petition; but unless such relief is given (and it will be observed that it cannot be given for a *corrupt* as distinguished from an illegal practice), an infringement of the Act may avoid the election altogether. The validity of the election may be questioned by election petition. Indeed, this is the only method when it is sought to set aside the election on any of the usual grounds, such as corrupt or illegal practices, or the disqualification of the candidate at the date of election. Election petitions against county councillors and members of other local bodies (borough councillors, urban and rural district councillors, members of school boards and boards of guardians) are classed together as municipal election petitions, and are heard in the same way, by a commissioner who must be a barrister of not less than fifteen years' standing. The petition is tried in open court at some place within the county, the expenses of the court being provided in the first instance by the Treasury, and repaid out of the county rates, except in so far as the court may order them to be paid by either of the parties. If a candidate is unseated a casual vacancy is created which has to be filled by a new election. A county councillor is required to accept office by making and subscribing a declaration in the prescribed form that he will duly and faithfully perform the duties of the office, and that he possesses the necessary qualification. The declaration may be made at any time within three months after notice of election. If the councillor does not make it within that time, he is liable to a fine the amount of which, if not determined by bye-law of the council, is £25 in the case of an alderman or councillor, and £50 in the case of the chairman. Exemption may, however, be claimed on the ground of age, physical or mental incapacity, previous service, or payment of the fine within five years, or on the ground that the claimant was nominated without his consent. If during his term of office a member of the council becomes bankrupt, or compounds with his creditors, or is (except in case of illness) continuously absent from the county, being chairman for more than two months, or being alderman or councillor for more than six months, his office becomes vacant by declaration of the council. In the case of disqualification by absence, the same fines are payable as upon non-acceptance of office, and the same liability arises on resignation. Acting without making the declaration, or without being qualified at the time of making the declaration, or after ceasing to be qualified, or after becoming disqualified, involves liability to a fine not exceeding £50, recoverable by action.

The councillors who have been elected come into office on the 8th March in the year of election. The first quarterly meeting of the newly-elected council is held on the 16th or on such other day within ten days after the 8th as the county council may fix. The first business at that meeting is the election of the chairman, whose office corresponds to that of the mayor in a borough. He is elected for the ensuing year, and holds office until his successor has accepted office. The chairman must by a fit person, elected by the council from their own body or from persons qualified to be councillors. He may receive such remuneration as the council think reasonable. He is by virtue of his office a justice of the peace for the county. Having elected the chairman, the meeting proceeds to the election of aldermen, whose number is one-third of the number of councillors, except in London, where the number is one-sixth. An alderman must be a councillor or a person qualified to be a councillor. If a councillor is elected he vacates his office of councillor, and thus creates a casual vacancy in the council. In every third year one-half of the whole number of aldermen go out of office, and their places are filled by election, which is conducted by means of voting papers. It will be observed, therefore, that while a county councillor holds office for three years, a county alderman holds office for six. The council may also appoint a vice-chairman who holds office during the term of office of the chairman; in London the council have power to appoint a paid deputy chairman.

It may be convenient at this point to refer to the officers of the county council. Of these, the chief are the clerk, the treasurer, and the surveyor. Before 1888 the clerk of the peace was appointed in a county by the *custos rotulorum*. He held office for life or good conduct, and had power to act by a sufficient deputy. Under the Act of 1888 existing clerks of the peace became clerks of the councils of their counties, holding office by the same tenure as formerly, except in the county of London,

where the offices were separated. Thereafter a new appointment to the offices of clerk of the peace and clerk of the county council was to be made by the standing joint-committee, at whose pleasure he is to hold office. The same committee appoint the deputy-clerk, and fix the salaries of both officers. The clerk of the peace was formerly paid by fees which were fixed by quarter sessions, but under recent enactments he is now generally if not in every case paid by salary, the fees received by him being paid into the county fund. The county council may also employ such other officers and servants as they may think necessary.

Subject to a few special provisions in the Local Government Act of 1888, the business of the county council is regulated by the provisions laid down in the Municipal Corporations Act, 1882, with regard to borough councils. There are four quarterly meetings in every year, the dates of which may be fixed by the council, with the exception of that which must be held on the 16th March or some day within ten days after the 8th of March as already noticed when treating of elections. Meetings are convened by notices sent to members stating the time and place of the meeting and the business to be transacted. The chairman, or in his absence the vice-chairman, or in the absence of both an alderman or councillor appointed by the meeting, presides. All questions are determined by the votes of the majority of those present and voting, and in case of equality of votes the chairman has a casting vote. Minutes of the proceedings are taken, and if signed by the chairman at the same or the next meeting of the council are evidence of the proceedings. In all other respects the business of the council is regulated by standing orders which the council are authorized to make. Very full power is given to appoint committees, which may be either general or special, and to them may be delegated, with or without restrictions or conditions, any of their powers or duties except that of raising money by rate or loan. Power is also given to appoint joint-committees with other county councils in matters in which the two councils are jointly interested, but a joint-committee so appointed must not be confounded with the standing joint-committee of the county council and the quarter sessions, which is a district statutory body and is elsewhere referred to. The finance committee is also a body with distinct duties.

In order to appreciate some of the points relating to the finance of a county council, it is necessary to indicate the relations between an administrative county and the boroughs which are locally situated within it. The Act of 1888 created a new division of boroughs into three classes; of these the first is the county borough. A certain number of boroughs which either had a population of not less than 50,000, or were counties of themselves, were made counties independent of the county council and free from the payment of county rate. In such boroughs the borough council have, in addition to their powers under the Municipal Corporations Act, 1882, all the powers of a county council under the Local Government Act. They are independent of the county council, and their only relation is that in some instances they pay a contribution to the county—*e.g.*, for the cost of assizes where there is no separate assize for the borough. The boroughs thus constituted county boroughs are enumerated in the schedule to the Local Government Act, 1888, but to the list therein contained there must now be added Grimsby, Oxford, and Newport (Mon.), which have been made county boroughs since 1888.

The larger quarter sessions boroughs, *i.e.*, those which had, according to the census of 1881, a population exceeding 10,000, form part of the county, and are subject to the control of the county council, but only for certain special purposes. The reason for this is that while in counties the powers and duties under various Acts were entrusted to the county authority, in boroughs they were exercised by the borough councils. In the class of boroughs now under consideration these powers and duties are retained by the borough council; the county council exercise no jurisdiction within the borough in respect of them, and the borough is not rated in respect of them to the county rate. The Acts referred to include those relating to the diseases of animals, destructive insects, explosives, fish conservancy, gas meters, margarine, police, reformatory

Relation of county to boroughs.

and industrial schools, riot (damages), sale of food and drugs, weights and measures. But for certain purposes these boroughs are part of the county and rateable to county rate—*e.g.*, main roads, cost of assizes and sessions, and in certain cases pauper lunatics. The county councillors elected for one of these boroughs may not vote on any matter involving expenditure on account of which the borough is not assessed to county rate.

The third class of boroughs comprises those which have a separate court of quarter sessions, but had according to the census of 1881 a population of less than 10,000. All such boroughs form part of the county for the purposes of pauper lunatics, analysts, reformatory and industrial schools, fish conservancy, explosives, and, of course, the purposes for which the larger quarter sessions boroughs also form part of the county, such as main roads, and are assessed to county rate accordingly. And in a borough, whether a quarter sessions borough or not, which had in 1881 a population of less than 10,000, all the powers which the borough council formerly possessed as to police, analysts, diseases of animals, gas meters, and weights and measures cease and are transferred to the county council, the boroughs becoming in fact part of the area of the county for these purposes.

It will be seen therefore that for some purposes, called in the Act general county purposes, the entire county, including all boroughs other than county boroughs, is assessed to the county rate; while for others, called special county purposes, certain boroughs are now assessed. This explanation is necessary in order to appreciate what has now to be said about county finance. But before leaving the consideration of the area of the county it may be added that all liberties and franchises are now merged in the county and subject to the jurisdiction of the county council.

The county council is a body corporate with power to hold lands. Its revenues are derived from various sources which will presently be mentioned, but all receipts have to be carried to the county fund, either to the general county account if applicable to general county purposes, or to the special county account if applicable to special county purposes. The county council may, with the consent of the Local Government Board, borrow money on the security of the county fund or any of its revenues, for consolidating the debts of the county; purchasing land or buildings; any permanent work or other thing, the cost of which ought to be spread over a term of years; making advances in aid of the emigration or colonization of inhabitants of the county; and any purpose for which quarter sessions or the county council are authorized by any Act to borrow. If, however, the total debt of the council will, with the amount proposed to be borrowed, exceed one-tenth of the annual rateable value of the property in the county, the money cannot be borrowed unless under a provisional order made by the Local Government Board and confirmed by Parliament. The period for which a loan is made is fixed by the county council with the consent of the Local Government Board, but may not exceed thirty years, and the mode of repayment may be by equal yearly or half-yearly instalments of principal or of principal and interest combined, or by means of a sinking fund invested and applied in accordance with the Local Government Acts. The loans authorized may be raised by debentures or annuity certificates under these Acts, or by the issue of county stock, and in some cases by mortgage.

The county council must appoint a finance committee for regulating and controlling the finance of the county, and the council cannot make any order for the payment of money out of the county fund save on the recommendation of that committee. Moreover, the order for payment of any sum must be made in

pursuance of an order of the council signed by three members of the finance committee present at the meeting of the council, and countersigned by the clerk. The order is directed to the county treasurer, by whom authorized payments are then made.

The accounts of the receipts and expenditure of the county council are made up for the twelve months ending the 31st March in each year, and are audited by a district auditor. The form in which the accounts must be made up is prescribed by the Local Government Board. The auditor is a district auditor appointed by the Local Government Board under the District Auditors Act, 1879, and in respect of the audit the council is charged with a stamp duty, the amount of which depends on the total of the expenditure comprised in the financial statement. Before each audit the auditor gives notice of the time and place appointed, and the council publish the appointment by advertisement. A copy of the accounts has to be deposited for public inspection for seven days before the audit. The auditor has the fullest powers of investigation; he may require the production of any books or papers, and he may require the attendance before him of any person accountable. Any owner of property or ratepayer may attend the audit and object to the accounts, and either on such objection or on his own motion the auditor may disallow any payment and surcharge the amount on the persons who made or authorized it. Against any allowance or surcharge appeal lies to the High Court if the question involved is one of law, or to the Local Government Board, who have jurisdiction to remit a surcharge if, in the circumstances, it appears to them to be fair and equitable to do so. It will be seen that this is really an effective audit.

The sources of revenue of the council are the Exchequer contribution, income from property and fees, and rates. Before 1888 large grants of money had been made annually to local authorities in aid of local taxation. Such grants represented a contribution out of taxation for the most part arising out of property other than real property, while local taxation fell on real property alone. By the Act of 1888 it was provided that for the future such annual grants should cease, and that other payments should be made instead thereof. The Commissioners of Inland Revenue pay into the Bank of England, to an account called "the local taxation account," the sums ascertained to be the proceeds of the duties collected by them in each county on what are called local taxation licences, which include licences for the sale of intoxicating liquor, licences on dogs, guns, establishment licences, &c. The amount so ascertained to have been collected in each county is paid under direction of the Local Government Board to the council of that county. The Commissioners of Inland Revenue also pay into the same account a sum equal to one and a half per cent. on the net value of personal property in respect of which estate duty is paid. Under the Customs and Inland Revenue Act, 1890, certain duties imposed on spirits and beer are also to be paid to "the local taxation account." The sums so paid in respect of the duties last above mentioned, and in respect of the estate duty and spirits and beer additional duties, are distributed among the several counties in proportion to the share which the Local Government Board certify to have been received by each county during the financial year ending the 31st March 1888, out of the grants theretofore made out of the Exchequer in aid of local rates. The payments so made out of "the local taxation account" to a county council are paid to the county fund, and carried to a separate account called "the Exchequer contribution account." The money standing to the credit of this account is applied: (i.) in paying any costs incurred in respect thereof or otherwise chargeable thereon; (ii.) in payment of the sums required by the Local Government Act, 1888, to be paid in substitution for local grants; (iii.) in payment of the new grant to be made by the county council in respect of the costs of union officers; and (iv.) in repaying to "the general county account" of the county fund the costs on account of general county purposes for which the whole area of the county (including boroughs other than county boroughs) is liable to be assessed to county contribution. Elaborate provision is made for the distribution of the surplus (if any), with a view to securing a due share being paid to the quarter sessions boroughs.

The payments which the county council have to make in substitution for the local grants formerly made out of Imperial funds include payments for or towards the remuneration of the teachers in poor-law schools and public vaccinators; school fees paid for children sent from a workhouse to a public elementary school; half of the salaries of the medical officer of health and the inspectors of nuisances of district councils; the remuneration of registrars for births and deaths; the maintenance of pauper lunatics; half of the cost of the pay and clothing of the police of the county, and of each borough maintaining a separate police force. In addition to the grants above mentioned, the county council is required to grant to the guardians of every poor-law union wholly or partly in their county an annual sum for the costs of the officers of the union and of district schools to which the

Revenue of
county
council.

union contributes. Another source is the income of any property belonging to the council, but the amount of this is usually small. The third source of revenue consists of the fees received by the different officers of the county councils or of the joint-committee. For example, fees received by the clerk of the peace, inspectors of weights and measures, and the like. These fees are paid into the county fund, and carried either to "the general county account" or, if they have been received in respect of some matter for which part only of the county is assessed, then to the special account to which the rates levied for that purpose are carried. The remaining source of income of a county council is the county rate, the manner of levying which is hereafter stated.

Of the powers and duties of county councils, it may be convenient to treat of these first, in so far as they are transferred to or conferred on them by the Local Government Act, 1888, under which they were created, and afterwards in so far as they have been conferred by subsequent legislation. Before the passing of the Local Government Act, 1888, the only form of county government in England was that of the justices in quarter sessions. Quarter sessions were originally a judicial body, but being the only body having jurisdiction over the county as a whole, certain powers were conferred and certain duties imposed upon them with reference to various matters of county government from time to time. The principal object of the Act of 1888 was to transfer these powers and duties from the quarter sessions to the new representative body—the county council; and it may be said that substantially the whole of the administrative business of quarter sessions was thus transferred.

The subjects of such transfer include (i.) the making, assessing, and levying of county, police, hundred, and all rates, and the application and expenditure thereof, and the making of orders for the payment of sums payable out of any such rate, or out of the county stock or county fund, and the preparation and revision of the basis or standard for the county rate. With regard to the county rate, a few words of description may be sufficient here. The council appoint a committee called a county rate committee, who from time to time prepare a basis or standard for county rate—that is to say, they fix the amount at which each parish in the county shall contribute its quota to the county rate. As a general rule the poor-law valuations are followed, but this is not universally the case, some county councils adopting the assessment to income tax, schedule A, and others forming an independent valuation of their own. The overseers of any parish aggrieved by the basis may appeal against it to quarter sessions, and it is to be noticed that this appeal is not interfered with, the transfer of the duties of justices relating only to administrative and not to judicial business. When a contribution is required from county rate, the county council assess the amount payable by each parish according to the basis previously made, and send their precept to the guardians of the unions comprising the several parishes in the county, the guardians in their turn requiring the overseers of each parish to provide the necessary quota of that parish out of the poor rate, and the sum thus raised goes into the county fund. The police rate is made for the purpose of defraying the expenses of the county police. It is made on the same basis as the county rate, and is levied with it. The hundred rate is seldom made, though in some counties it may be made for purposes of main roads and bridges chargeable to the hundred as distinguished from the county at large; (ii.) the borrowing of money; (iii.) the passing of the accounts of and the discharge of the county treasurer; (iv.) shire halls, county halls, assize courts, the judges' lodgings, lock-up houses, court houses, justices' rooms, police stations and county buildings, works, and property; (v.) the licensing under any general Act of houses and other places for music or for dancing, and the granting of licences under the Racecourses Licensing Act, 1879; (vi.) the provision, enlargement, maintenance, and management and visitation of, and other dealing with, asylums for pauper lunatics; (vii.) the establishment and maintenance of, and the contribution to, reformatory and industrial schools; (viii.) bridges and roads repairable with bridges, and any powers vested by the Highways and Locomotives Amendment Act, 1878, in the county authority. It may be observed that bridges have always been at common law repairable by the county, although, with regard to bridges erected since the year 1805, these are not to be deemed to be county bridges repairable by the county unless they have been erected under the direction or to the satisfaction of the county surveyor. The common-law liability to repair a bridge extends also to the road or approaches for a distance of 300 feet on each side of the bridge. Of the powers vested in the county authority under the

Highway Act, 1878, the most important are those relating to main roads, which are specially noticed hereafter. (ix.) The table of fees to be taken by and the costs to be allowed to any inspector, analyst, or person holding any office in the county other than the clerk of the peace and the clerks of the justices; (x.) the appointment, removal, and determination of salaries of the county treasurer, the county surveyor, the public analysts, any officer under the Explosives Act, 1875, and any officers whose remuneration is paid out of the county rate, other than the clerk of the peace and the clerks of the justices; (xi.) the salary of any coroner whose salary is payable out of the county rate, the fees, allowances, and disbursements allowed to be paid by any such coroner, and the division of the county into coroners' districts and the assignments of such districts; (xii.) the division of the county into polling districts for the purposes of parliamentary elections, the appointment of the places of election, the places of holding courts for the revision of the lists of voters, and the costs of and other matters to be done for the registration of parliamentary voters; (xiii.) the execution as local authority of the Acts relating to contagious diseases of animals, to destructive insects, to fish conservancy, to wild birds, to weights and measures, and to gas meters, and of the Local Stamp Act, 1869; (xiv.) any matters arising under the Riot (Damages) Act, 1886. Under this Act compensation is payable out of the police rate to any person whose property has been injured, stolen, or destroyed by rioters; (xv.) the registration of rules of scientific societies, the registration of charitable gifts, the certifying and recording of places of religious worship, the confirmation and record of the rules of loan societies. These duties are imposed under various statutes.

In addition to the business of quarter sessions thus transferred, there was also transferred to the county council certain business of the justices of the county out of session, that is to say, in petty or special sessions. This business consists of the licensing of houses or places for the public performance of stage plays, and the execution, as local authority, of the Explosives Act, 1875. Power was given by the Act to the Local Government Board to provide, by means of a provisional order, for transferring to county councils any of the powers and duties of the various central authorities which have been already referred to; but although such an order was at one time prepared, it has never been confirmed, and nothing has been done in that direction.

Apart from the business thus transferred to county councils, the Act itself has conferred further powers or imposed further duties with reference to a variety of other matters, some of which must be noticed. But before passing to them it is necessary here to call attention to one important subject of county government which has not been wholly transferred to the county council, namely, the police. It was matter of considerable discussion before the passing of the Act whether the police should remain under the control of the justices, or be transferred wholly to the control of the county council. Eventually a middle course was taken. The powers, duties, and liabilities of the quarter sessions and justices out of session with respect to the county police were vested in the quarter sessions and the county council jointly, and are now exercised through the standing joint-committee of the two bodies. That committee consists of an equal number of members of the county council and of justices appointed by the quarter sessions, the number being arranged between the two bodies or fixed by the Secretary of State. The committee are also charged with the duties of appointing or removing the clerk of the peace, and they have jurisdiction in matters relating to justices' clerks, the provision of accommodation for quarter sessions or justices out of session, and the like, and their expenses are paid by the county council out of the county fund. The standing joint-committee have power to divide their county into police districts, and, when required by Order in Council, are obliged to do so. In such a case, while the general expenditure in respect of the entire police force is defrayed by the county at large, the local expenditure, *i.e.*, the cost of pay, clothing, and such other expenses as the joint-committee may direct, are defrayed at the cost of the particular district for which it is incurred (see also POLICE).

Among the powers and duties given to county councils by the Local Government Act, 1888, the first to be mentioned, following the order in the Act itself, is that of the appointment of county coroners. The office of coroner is a very ancient one, and was formerly of much greater dignity and importance than it is at present. The duties of a coroner are now limited to the holding of inquiries into cases of death from causes suspected to be other than natural, and to a few miscellaneous duties of comparatively rare occurrence, such as the holding of inquiries relating to treasure trove, and acting instead of the sheriff on inquiries under the Lands Clauses Act, &c., when that officer is interested and thereby disabled from holding such inquiries. The office of coroner is a freehold one, that is to say, it is held for life or good conduct, and in a county the salary of the coroner is paid out of the county fund. Formerly he was elected by the freeholders of the county in pursuance of a writ *de coronatore eligendo*. The power of appointment is now given to the county

Powers transferred from quarter sessions.

Police.

County coroners.

council, who may appoint any fit person, not being a county alderman or county councillor, to fill the office, and in the case of a county divided into coroners' districts, may assign him a district. It has been decided, however, that the power hereby conferred does not extend to the appointment of a coroner for a liberty or other franchise who would not under the old law have been appointed by the freeholders. It may be mentioned that though a coroner may have a district assigned to him, he is nevertheless a coroner for the entire county throughout which he has jurisdiction.

It was provided by the Highway Act, 1878, that every road which was disturnpiked after the 31st December 1870 should be deemed to be a main road, the expenses of the repair and maintenance of which were to be contributed as to one-half thereof by the justices in quarter sessions, then the county authority. By another section of the same Act it was provided that where any highway in a county was a medium of communication between great towns, or a thoroughfare to a railway station, or otherwise such that it ought to be declared a main road, the county authority might declare it to be a main road, and thereupon one-half the expense of its maintenance would fall upon the county at large. Once a road became a main road it could only cease to be such by order of the Local Government Board. As already stated, the powers of the quarter sessions under the Act of 1878 were transferred to the county council under the Local Government Act of 1888, and that body alone has now power to declare a road to be a main road. But the Act of 1888 made some important changes in the law relating to the maintenance of main roads. It declared that thereafter not only the half but the whole cost of maintenance should be borne by the county. Provision is made for the control of main roads in urban districts being retained by the urban district council. In urban districts where such control has not been claimed, and in rural districts, the county council may either maintain the main roads themselves or allow or require the district councils to do so. The county council must in any case make a payment towards the costs incurred by the district council, and if any difference arises as to the amount of it, it has to be settled by the Local Government Board. In Lancashire the cost of main roads falls upon the hundred, as distinguished from the county at large, special provision being made to that effect. Special provision has also been made for the highways in the Isle of Wight and in South Wales, where the roads were formerly regulated by special acts, and not by the ordinary Highway Acts.

The county council have the same power as a sanitary authority to enforce the provisions of the Rivers Pollution Prevention Acts in relation to so much of any stream as passes through or by any part of their county. Under these Acts a sanitary authority is authorized to take proceedings to restrain interference with the due flow of a stream or the pollution of its waters by throwing into it the solid refuse of any manufactory or quarry, or any rubbish or cinders, or any other waste, or any putrid solid matter. They may also take proceedings in respect of the pollution of a stream by any solid or liquid sewage matter. They have the same powers with respect to manufacturing and mining pollutions, subject to certain restrictions, one of which is that proceedings are not to be taken without the consent of the Local Government Board. The county council may not only themselves institute proceedings under the Acts, but they may contribute to the costs of any prosecution under the Acts instituted by any other county or district council. The Local Government Board is further empowered by provisional order to constitute a joint-committee representing all the administrative counties through or by which a river passes, and confer on such committee all or any of the powers of a sanitary authority under the Acts.

A county council has the same power of opposing Bills in Parliament and of prosecuting or defending any legal proceedings necessary for the promotion or protection of the interests of the inhabitants of a county as are conferred on the council of a municipal borough by the Borough Funds Act, 1872, with this difference, that in order to enable them to oppose a Bill in Parliament at the cost of the county rate, it is not necessary to obtain the consent of the owners and ratepayers within the county. The power thus conferred is limited to opposing Bills. The council are not authorized to promote any Bill, and although they frequently do so, they incur the risk that if the bill should not pass the members of the council will be surcharged personally with the costs incurred if they attempt to charge them to the county rate. Of course if the Bill passes, it usually contains a clause enabling the costs of promotion to be paid out of the county rate. It must not be supposed, however, that the county council have no power to institute or defend legal proceedings or oppose Bills save such as is expressly conferred upon them by the Local Government Act. In this respect they are in the same position as all other local authorities, with respect to whom it has been laid down that they may without any express power in that behalf use the funds at their disposal for protecting themselves against any attack made upon

their existence as a corporate body or upon any of their powers or privileges.

The county council have also the same powers as a borough council of making bye-laws for the good government of the county and for the suppression of nuisances not already punishable under the general law. This power has been largely acted upon throughout England, and the courts of law have on several occasions decided that such bye-laws should be benevolently interpreted, and that in matters which directly arise and concern the people of the county, who have the right to choose those whom they think best fitted to represent them, such representatives may be trusted to understand their own requirements. Such bye-laws will therefore be upheld, unless it is clear that they are uncertain, repugnant to the general law of the land, or manifestly unreasonable. It may be mentioned that, while bye-laws relating to the good government of the county have to be confirmed by the Secretary of State, those which relate to the suppression of nuisances have to be confirmed by the Local Government Board. Such confirmation, however, though necessary to enable the council to enforce them, does not itself confer upon them any validity in point of law.

The county council have power to appoint and pay one or more medical officers of health, who are not to hold any other appointment or engage in private practice without the express written consent of the council. The council may make arrangements whereby any district council or councils may have the services of the county medical officer on payment of a contribution towards his salary, and while such arrangement is in force the duty of the district council to appoint a medical officer is to be deemed to have been satisfied. Every medical officer, whether of a county or district, must now be legally qualified for the practice of medicine, surgery, and midwifery. Besides this, in the case of a county, or of any district or combination of districts of which the population exceeds 50,000, the medical officer must also have a diploma in public health, unless he has during the three consecutive years before 1892 been medical officer of a district or combination having a population of more than 20,000, or has before the passing of the Act been for three years a medical officer or inspector of the Local Government Board.

The only other powers and duties of a county council arising under the Local Government Act itself which it is necessary to notice are those relating to alterations of local areas.

It may be convenient here to state that certain alterations of areas can only be effected through the medium of the Local Government Board after local inquiry.

These cases include the alteration of the boundary of any county or borough, the union of a county borough with a county, the union of any counties or boroughs or the division of any county, the making of a borough into a county borough. In these cases the order of the Local Government Board is provisional only, and must be confirmed by Parliament. The powers of a county council to make orders for the alteration of local areas are as follows: When a county council is satisfied that a *primâ facie* case is made out as respects any county district not a borough, or as respects any parish, for a proposal for all or any of the things hereafter mentioned, they may hold a local inquiry after giving such notice in the locality and to such public departments as may be prescribed from time to time by the orders of the Local Government Board. The things referred to include the alteration of the boundary of the district or parish; the division or union thereof with any other district or districts, parish or parishes; the conversion of a rural district or part thereof into an urban district, or *vice versâ*. In these cases, after the local inquiry above referred to has been held, the county council, being satisfied that the proposal is desirable, may make an order for the same accordingly. The order has to be submitted to the Local Government Board, and that Board must hold a local inquiry in order to determine whether the order should be confirmed or not, if the council of any district affected by it, or one-sixth of the total number of electors in the district or parish to which it relates, petition against it. The Local Government Board have power to modify the terms of the order whether it is petitioned against or not, but if there is no petition, they are bound to confirm, subject only to such modifications. Very large powers are conferred upon county councils for the purpose of giving full effect to orders made by them under these provisions. A considerable extension of the same powers was made by the Local Government Act, 1894, which practically required every council to take into consideration the areas of sanitary districts and parishes within the entire administrative county, and to see that a parish did not extend into more than one sanitary district; to provide for the division of a district which did extend into more than one district into separate parishes, so that for the future the parish should not be in more than one county district; and to provide for every parish and rural sanitary district being within one county. An enormous number of orders under the Act of 1894 was made by county councils, and, speaking generally, it will now be found that no parish extends into more

Bye-laws.**Medical officers.****Alterations of local areas.****Main roads.****Rivers pollution prevention.****Parliamentary and legal costs.**

than one county or county district. Other powers and duties of the county council under the Act of 1894 will be noticed hereafter.

Of the statutes affecting county councils passed subsequent to 1888 mention need only be made of the chief.

Under the Technical Instruction Acts a county council are authorized out of the county fund to supply or aid the supply of technical or manual instruction. The amount to be raised in any one year is not to exceed the sum of one penny in the £. The county council is also empowered to make contributions for the purpose of technical education out of the sums received by them in respect of the residue of the English share of the local taxation (Customs and Excise) duties already referred to. Such contributions may be made over and above the limited amount which may be raised by rates. Provision is also made enabling the managers of any school for science and art or of any institution in the nature of a literary and scientific institution to transfer the school or institution to the county council.

Part of the business transferred from quarter sessions to the council was that which related to pauper lunatics, but the whole subject of lunacy was consolidated by an Act of the year 1890, which again has been amended by a later Act.

Lunatics.

The councils of all administrative counties and county boroughs and the councils of a few specified quarter sessions boroughs, which before 1890 were independent areas for purposes of the Lunacy Acts, are local authorities for the purposes of the Lunacy Acts, and each of them is under an obligation to provide asylum accommodation for pauper lunatics. This accommodation may be provided by one council or by a combination of two or more, and such council or combination may provide one or more asylums. The county council exercise their powers through a visiting committee, consisting of not less than seven members, or, in the case of a combination, of a number of members appointed by each council in agreed proportions. In the case of a combination the expenses are defrayed by the several councils in such proportion as they may agree upon, and the proportion may be fixed with reference to either the accommodation required by each council or the population of the district. A county borough may also, instead of providing an asylum of its own, contract with the visiting committee of any asylum to receive the pauper lunatics from the borough. Private patients may be accommodated in the asylums provided by a county council, and received upon terms fixed by the visiting committee. The expenses of lunatic asylums are defrayed in the following manner: The guardians from whose union a lunatic is sent have to pay a fixed weekly sum, which may not exceed 14s. a week. A larger charge is made for lunatics received from unions outside the county, as these do not, of course, contribute anything towards the provision or up-keep of the asylum itself. In addition to the payments by guardians, there is a contribution of 4s. a week from "the Exchequer contribution account" already mentioned, and the remaining expenses are defrayed out of the county rate.

Under the Allotments Acts, if a district council fail to provide allotments upon being required so to do, application may be made to the county council, who may thereupon take upon themselves the powers of a district council and provide the allotments required in the district whose council have made default. Moreover, the county council under these Acts may give compulsory powers of purchase to a district council if the latter cannot obtain a sufficient quantity of suitable land by agreement. They cannot, however, make orders for this purpose except after local inquiry, and, in the event of objection, their orders must be confirmed by the Local Government Board. If the county council refuse to make an order, the Local Government Board may make it after holding local inquiry.

A county council may, under the Small Holdings Act, 1892, acquire land by agreement, and improve and adapt it for the purpose of providing small holdings for persons who desire to have such holdings for cultivation. Such holdings must not exceed 50 acres in extent or £50 annual value. The purchaser has to pay down at least one-fifth of the purchase money; the balance is charged on the holding and may be repaid by instalments extending over a period not exceeding fifty years. A county council may borrow for purposes of the Act referred to.

Under the Isolation Hospitals Act, 1893, a county council may provide for the establishment of isolation hospitals for the reception of patients suffering from infectious diseases on the application of any local authority within the county, or on the report of the medical officer of the county that hospital accommodation is necessary and has not been provided. The council by their order constitute a hospital district and form a committee for its administration. The committee have power to purchase land, erect a hospital, provide all necessary appliances, and generally administer a hospital for the purposes above mentioned.

The powers and duties of a county council under the Local Government Act, 1894, are numerous and varied, and the chief of them are mentioned hereafter in connexion with parish councils. The county council may establish a parish council in a parish which has a population of less than 300, and may group small parishes under a common parish council; in every case they fix the number of members of the parish council. They may authorize a parish council to acquire land compulsorily, subject to confirmation of their order by the Local Government Board if it is petitioned against. They may make an order authorizing a parish council to hire land compulsorily for allotments. They may authorize the borrowing of money by a parish council, and they may lend money to a parish council. They may hear complaints by a parish council that a district council has failed to provide sufficient sewerage or water-supply, or has failed to enforce the provisions of the Public Health Acts in their district, and on such complaint they may transfer to themselves and exercise the powers of the defaulting council, or they may appoint a person to perform those duties. They may make orders for the custody and preservation of public books, writings, papers, and documents belonging to a parish. They may divide a parish into wards for purposes of elections or of parish meetings. They may authorize district councils to aid persons in maintaining rights of common. They may, on the petition of a district council, transfer to themselves the powers of a district council who have refused or failed to take the necessary proceedings to assert public rights of way or protect roadside wastes. They may dispense with the disqualification of a parish or district councillor arising only by reason of his being a shareholder in a water company or similar company contracting with the council, and, as has above been stated, they have large powers of altering the boundaries of parishes.

Parish councils.

Among the powers and duties of quarter sessions transferred to county councils were those arising under the Acts relating to contagious diseases of animals. These Acts were consolidated and amended by a statute of 1894, and the county council remain the local authority for the execution of that Act in counties.

Diseases of animals.

Under the Light Railways Act, 1896, a county council may be authorized by order of the Light Railway Commissioners to construct and work or contract for the construction or working of a light railway, lend money to a light railway company, or join any other council in these matters.

Light railways.

Among other statutes conferring powers or imposing duties upon county councils, mention may be made of such Acts as those relating to sea fisheries regulation, open spaces, police superannuation, railway and canal traffic, shop hours, weights and measures, fertilizing and feeding stuffs, wild birds' protection, land transfer, locomotives on high-ways, and the acquisition of small dwellings. Sufficient has been said to indicate that the Legislature from time to time recognizes the important position of the county council as an administrative body, and is continually extending their functions.

Miscellaneous.

A municipal borough is a place which has been incorporated by royal charter. In the year 1835 the Municipal Corporations Act was passed, which made provision for the constitution and government of certain boroughs which were enumerated in a schedule. That Act was from time to time amended, until in 1882 by an Act of that year the whole of the earlier Acts were repealed and consolidated. A few ancient corporations which were not enumerated in the schedule to the Act of 1835 continued to exist after that year, but by an Act of 1883 all of these, save such as should obtain charters before 1886, were abolished, the result being that all boroughs are now subject to the Act of 1882. A place is still created a borough by royal charter on the petition of the inhabitants, and when that is done the provisions of the Act of 1882 are applied to it by the charter itself. The charter also fixes the number of councillors, the boundaries of the wards (if any), and assigns the number of councillors to each ward, and provides generally for the time and manner in which the Act of 1882 is first to come into operation. The charter is supplemented by a scheme which makes provision for the transfer to the new borough council of the powers and duties of existing authorities, and generally for the bringing into operation of the Act of 1882. If the scheme is opposed by the prescribed pro-

The municipal borough and the borough council.

portion (one-twentieth) of the owners and ratepayers of the proposed new borough, it has to be confirmed by Parliament. The governing body in a borough is the council elected by the burgesses.

The qualification of a burgess has been incidentally mentioned in connexion with that of a county elector, and need not be further noticed. A borough councillor must be qualified in the same manner as a county councillor, and he is disqualified in the same way, with this addition, that a peer or ownership voter is not qualified as such, and that a person is disqualified for being a borough councillor if he is in holy orders or is the regular minister of a Dissenting congregation. Borough councillors are elected for a term of three years, one-third of the whole number going out of office in each year, and if the borough is divided into wards, these are so arranged that the number of councillors for each ward shall be three or a multiple of three. The ordinary day of election is the 1st November. At an election for the whole borough the returning officer is the mayor; at a ward election he is an alderman assigned for that purpose by the council. The nomination and election of candidates and the procedure at the election are the same as have already been described in the case of the election of county councillors. The law as to corrupt and illegal practises at the election is also similar, and the election may be questioned by petition in exactly the same way. A borough councillor must, within five days after notice of his election, make a declaration of acceptance of office under a penalty, in the case of an alderman or councillor of £50, and in the case of a mayor of £100, or such other sums as the council may by bye-law determine. A councillor may be disqualified in the same way as a county councillor, by bankruptcy or composition with creditors, or continuous absence from the borough (except in case of illness). In short it may be said that as the provisions relating to the election of borough councillors were merely extended to county councillors by the Local Government Act of 1888 with a few modifications, these provisions, as already stated when dealing with county councils, apply generally to the election of borough councillors. After the annual election on the 1st November the first quarterly meeting of the council is held on the 9th, and at that meeting the mayor and aldermen are elected. The election of the mayor and aldermen is again the same as has already been described in connexion with the election of the chairman and aldermen of a county council.

Officers. The officers of a borough council are the town clerk and the treasurer, but the council have power to appoint such other officers as they think necessary. All these officers receive such remuneration as the council from time to time think fit, and hold office during pleasure. The provisions with respect to the transaction of the business of the council are also the same in the case of a borough as in that of a county council.

The entire income of the borough council is paid into the borough fund, and that fund is charged with certain payments, which are specifically set out in the 5th schedule to the Act of 1882. These include the remuneration of the mayor, recorder, and officers of the borough, overseers' expenses, the expenses of the administration of justice in the borough, the payment of the borough coroner, police expenses, and the like. An order of the council for the payment of money out of the borough fund must be signed by three members of the council and countersigned by the town clerk, and any such order may be removed into the King's Bench Division of the High Court of Justice by writ of *certiorari*, and may be wholly or partly disallowed or confirmed on the hearing. This is really the only way in which the validity of a payment by a borough council can be questioned, for, as will be seen hereafter, the audit in the borough is not an effective one. The borough fund is derived, in the first instance, from the property of the corporation. If the income from such property is insufficient for the purposes to which it is applicable, as usually is the case, it has to be supplemented by a borough rate, which may be a separate rate made by the council or may be levied through the overseers as part of the poor rate by means of a precept addressed to them. In the event of the borough fund being more than sufficient to meet the demands upon it without recourse to a borough rate, any surplus may be applied in payment of any expenses of the council as a sanitary authority or in improving the borough or any part thereof by drainage, enlargement of streets, or otherwise. The borough treasurer is required to make up his accounts half-yearly, and to submit them, with the necessary vouchers and papers, to the borough auditors. These auditors are three in number—two of them elected annually by the burgesses. An elective auditor must be qualified to be a councillor, but may not be a member of the council. The third auditor is appointed by the mayor and is called the mayor's auditor. The auditors so appointed are charged with the duty of auditing the accounts of the treasurer, but they have no power of disallowance or surcharge, and their audit is therefore quite ineffective.

Where a borough has not a separate court of quarter sessions, but has a separate commission of the peace, the justices of the county in which the borough is situate have a concurrent jurisdiction with the borough justices in all matters arising within the borough. Where, however, the borough has a court of quarter sessions, the county justices have no jurisdiction within the borough. In all cases, whether the borough has quarter sessions or a separate commission or not, the mayor, by virtue of his office, is a justice for the borough, and continues to be such justice during the year next after he ceases to be mayor. He takes precedence over all justices acting in and for the borough, and is entitled to take the chair at all meetings at which he is present by virtue of his office of mayor. A separate commission of the peace may be granted to a borough on the petition of the council. A borough justice is required to take the oaths of allegiance and the judicial oaths before acting; he must while acting reside in or within seven miles of the borough, or occupy a house, warehouse, or other property in the borough; but he need not be a burgess nor have the qualification by estate required of a county justice. Where the borough has a separate commission, the borough justices have power to appoint a clerk, who is now paid by salary, the fees and costs pertaining to his office being paid into the borough fund, out of which his salary is paid. The council may by petition obtain the appointment of a stipendiary magistrate for the borough. The Crown may also on petition of the council grant a separate court of quarter sessions for the borough, and in that event a recorder has to be appointed by the Crown. He must be a barrister of not less than five years' standing, and he holds office during good behaviour; he receives a yearly salary. The recorder sits as sole judge of the court of quarter sessions of the borough. He has all the powers of a court of quarter sessions in a county, including the power to hear appeals from the borough justices; but to this there are a few exceptions, notably the power to grant licences for the sale of intoxicating liquor. The grant of a separate court of quarter sessions also involves the appointment by the council of a clerk of the peace for the borough. It should be added that the grant of a court of quarter sessions to any borough other than a county borough after the passing of the Local Government Act, 1888, does not affect the powers, duties, or liabilities of the county council as regards that borough, nor exempt the parishes in the borough from being assessed to county rate for any purposes to which such parishes were previously liable to be assessed.

Jurisdiction of justices; quarter sessions.

When a borough is a county of itself the council appoint a sheriff on the 9th November in every year. And where the borough has a separate court of quarter sessions the council appoint a fit and proper person, not an alderman or councillor, to be the borough coroner, who holds office during good behaviour. If the borough has a civil court the recorder, if there is one, is judge of it. If there is no recorder, the judge of the court is an officer of the borough appointed under the charter.

Sheriff, coroner.

The provisions of the Municipal Corporations Act, 1882, relate chiefly to the constitution of the municipal corporation. It does not itself confer many powers or impose many duties upon the council as a body. It does, however, enable a municipal corporation to acquire corporate land and buildings, the buildings including a town hall, council house, justices' room, police stations and cells, sessions house, judges' lodgings, polling stations, and the like. The council may borrow money for the erection of such buildings; they may acquire and hold land in mortmain by virtue of their charter or with the consent of the Local Government Board. Corporate land cannot be alienated without the consent of the same board. The council may convert corporate land, with the approval of the Local Government Board, into sites for workmen's dwellings.

Power to acquire land.

Another duty imposed upon a borough council by the Act of 1882 is the maintenance of bridges within the borough which are not repairable by the county in which the borough is locally situate. It may here be mentioned that a city or borough which is a county of itself is liable at common law to repair all public bridges within its limits. In a borough which is not a county of itself the inhabitants are only liable to repair bridges within the borough by immemorial usage or custom.

Borough bridges.

Of the other powers possessed by the council of a borough under the Act of 1882, one of the most important is the power to make bye-laws for the good rule and government of the borough, and for the prevention and suppression of nuisances not already punishable in summary manner by virtue of an Act in force throughout the borough. It will be observed that these bye-laws are of two classes. The former do not come into force until the expiration of forty days after a copy of them has been sent to the Secretary of State, during which forty days the Sovereign in council may disallow any bye-law or part thereof. The latter require to be confirmed by the Local Government Board.

Bye-laws.

Under the Act of 1882 every municipal borough might have its own separate police force. As has already been stated when dealing

with county councils, boroughs having a population of less than 10,000 according to the census of 1881 can no longer have a separate police force. But for some time before that year it had become the rule not to grant to any new borough with a population of less than 20,000 a separate police force. The subject of police is separately treated in the *Encyclopædia Britannica*, and it is not necessary to supplement what is there stated. Under an Act of 1893 the borough police may, in addition to their ordinary duties, be employed to discharge the duties of a fire brigade.

The powers and duties of a borough council in the Municipal Corporations Act do not arise or exist to any great extent under that Act. In a few cases, those namely of county boroughs, the councils have the powers of county councils. In the quarter sessions boroughs other than county boroughs they have some only of these powers. But in every case the council of the borough have the powers and duties of an urban district council, and, except where they derive their authority from local Acts, it may be said that their principal powers and duties consist of those which they exercise or perform as an urban council. These will now be considered.

Before the year 1848 there was not outside the municipal boroughs any system of district government in England. It is true that in some populous places which were not corporate boroughs local Acts of Parliament had been passed appointing improvement commissioners for the government of these places. In many boroughs similar Acts had been obtained conferring various powers relating to sanitary matters, streets and highways, and the like. But there was no general system, nor was there, save by special legislation, any means by which sanitary districts could be constituted. In the year 1848 the first Public Health Act was passed. It provided for the formation of local boards in boroughs and populous places, such places outside boroughs being termed local government districts. In boroughs the town council were generally appointed the local board for purposes of the Act. It was not, however, until 1872 that a general system of sanitary districts was adopted. By the Public Health Act of that year the whole country was mapped out into urban and rural sanitary districts, and that system has been maintained until the present time, with some important changes introduced by the Public Health Act, 1875, and the Local Government Act, 1894.

The whole of England and Wales is divided into districts, which are either urban or rural. Urban districts include boroughs and places which were formerly under the jurisdiction of local boards or improvement commissioners. The power to constitute new urban districts is now conferred upon county councils, as already stated. There is a concurrent power in the Local Government Board under the Public Health Act, 1875, but that power is now rarely exercised, and new urban districts are in practice created only by orders of county councils made under the Local Government Act, 1888, section 57. Rural districts were first created in 1872. Before that time there was practically no sanitary authority outside the urban district, for although the vestry of a parish had in some cases power to make sewers and had also some other sanitary powers, there was no authority for such a district as now corresponds to a rural district. There were, indeed, highway boards and burial boards which had powers for special purposes, but district authority in the sense in which it is now understood there was none. Before the year 1894 the rural district consisted of the area of the poor-law union, exclusive of any urban district which might be within it, and the guardians of the poor were the rural sanitary authority. Since 1894 this has been changed. By the Local Government Act of that year the guardians ceased to be the rural sanitary authority. The union was preserved as the rural sanitary district, with this qualification, that if it extended into more than one county it was divided so that no rural district should extend into more than one county. Rural district councillors are elected for each parish in the rural district, and they become by virtue of their office guardians of the poor for the union comprising the district, so that there is now no election of guardians in a rural district. Guardians are still elected as such for urban districts, but the rural district council have ceased to be the same body as the guardians and are now wholly distinct. A district councillor, whether urban or rural, holds

office for a term of three years. One-third of the whole council retire in each year, the annual elections being held in March, but there may be a simultaneous retirement of the whole council in every third year if the county council at the instance of the district council so order. The qualification and disqualification of district councillors, whether urban or rural, now depend upon the Local Government Act, 1894. Property qualification is abolished. Any person may be elected who is either a parochial elector of some parish within the district or has during the whole of the twelve months preceding his election resided in the district, and no person is disqualified by sex or marriage. The electors both in urban and rural districts are the body called the parochial electors. These are practically the persons whose names appear in the Parliamentary Register or in the Local Government Register as being entitled to vote at elections for members of Parliament or county or parish councillors as the case may be. The election takes place subject to rules made by the Local Government Board, these rules being largely founded upon adaptations of the Municipal Corporations Act, 1882. The rules issued 1st January 1898 will be found in the *Statutory Rules and Orders, 1898*, pp. 264, 302. The election is by ballot on the same lines as those prescribed for a municipal election, and the Corrupt Practices Act, the provisions of which have been referred to when dealing with county councils, applies to the elections of district councils. The provisions with reference to election petitions, the grounds upon which they may be presented and the procedure upon them, are the same in every respect as have already been mentioned when dealing with county councils. It may be convenient here to state that the Local Government Board has power to unite any number of districts or parts of districts into what is called a united district for certain special purposes such as water-supply, sewerage, or the like. This is done by means of a provisional order made by the board and confirmed by Parliament. In such a united district the governing body is a joint board constituted in manner provided by the order, and it has under the order such of the powers of a district council as are necessary for the purposes for which the united district is created. Thus a joint sewerage board would generally be invested by the order with all the powers of a district council relating to the provision and control of sewers and the disposal of sewage. It may also be convenient here to mention another special kind of district authority, that is, a

United districts.

port sanitary authority. It is also constituted by order of the Local Government Board, and it may include one or more sanitary districts or parts of districts abutting upon a port. In this case also the authority consists of such members and is elected in such manner as the order determines, and it has such of the powers of an ordinary district council as the order may confer upon it. These relate for the most part to nuisances and infectious disease, having special reference to ships. It has been thought convenient to deal here with district councils, whether urban or rural, together, but the powers of the former are much more extensive than those of the latter, and as the consideration of the subject proceeds it will be necessary to indicate what powers and duties are conferred or imposed upon urban district councils only. It must be pointed out, however, that when the necessity arises for conferring upon a rural district council any of the powers exercisable only by an urban district council, that can be done by means of an order of the Local Government Board. The necessity for this provision arises because it sometimes happens that in a district otherwise rural there are some centres of population, hardly large enough to be constituted urban districts, which nevertheless require the same control as an urban district. Thus it may be desirable to confer upon a rural district council in respect of such a populous area the power to make up private streets, or to make bye-laws relating to new streets and buildings, and similar purposes.

Port sanitary authority.

Powers of urban and rural councils compared.

A district council may from time to time make regulations with respect to summoning, notice, place, management, and adjournment of their meetings and generally with respect to the transaction and management of their business. Three members must be present to constitute a quorum. At the annual meeting, which is held as soon as convenient after the 15th April in each year, a chairman for the succeeding year has to be appointed. He presides at all meetings, and in his absence another member appointed by the meeting takes his place. Questions are determined by the majority present and voting, the chairman having the casting vote. Minutes are taken and, if signed at the meeting or the next ensuing meeting, are made evidence. The officers of the council consist of a clerk, a medical officer, a surveyor, one or more inspectors of nuisances, and a treasurer. Of these all but the medical officer of health and inspectors of nuisances hold office at pleasure and receive such remuneration as the council may determine. If the urban district is a borough, the town clerk and borough treasurer fulfil the same office for purposes of the Public Health Acts. The salaries of the medical

Business and offices.

officer of health and inspectors of nuisances are, as to one moiety thereof, paid out of "the Exchequer contribution account" by the county council, if they are appointed in accordance with the requirements of the Local Government Board as to qualification, appointment, duties, salary, and tenure of office. The orders of the Local Government Board as to these matters are set out in the *Statutory Rules and Orders, 1891*, pp. 527, 539. District councils may also employ such other officers and servants as may be necessary and proper for the fulfilment of their duties. Officers and servants are prohibited from being concerned or interested in any bargain or contract made with their council, and from receiving under cover of their office or employment any fee or reward whatsoever other than their proper salaries, wages, and allowances, under penalty of being rendered incapable of holding office under any district council, and of a pecuniary penalty of £50. There are some exceptions to this provision somewhat similar to those already mentioned with respect to the disqualification of members of the council. It may be mentioned here that by an Act, called the Public Bodies' Corrupt Practices Act, 1889, severe penalties are imposed alike upon members and officers of public bodies for corruption in office.

A district council may appoint committees consisting wholly or partly of members of their own body for the exercise of any powers which in their opinion can properly be exercised by such committees. Such committees do not, however, hold office beyond the next annual meeting of the council, and their acts must be submitted to the council for their approval. If they are appointed for any purposes of the Public Health or Highway Acts, the council may authorize them to institute any proceedings or do any act which the council might have instituted or done, other than the raising of any loan or the making of any rate or contract. A rural district council may delegate their entire powers in any parish to a parochial committee. Such committee may consist wholly of members of their own body or of members of the parish council, or partly of members of both. Such a committee may be subject to any regulations and restrictions imposed upon it by the rural district council.

In dealing with the powers and duties of district councils it will be convenient to treat of these first as they arise under the Public Health Acts, and afterwards as they arise under other statutes. In so far as such powers and duties are common to urban and rural district councils alike they will be referred to as appertaining to district councils. When reference is made to any power or duty of an urban council it is to be understood that the rural council have no such power or duty unless conferred or imposed upon them by order of the Local Government Board. And it must be borne in mind that in a borough the borough council are the urban district council.

The district council are required to cause to be made such sewers as may be necessary for effectually draining their district. This duty may be enforced by the Local Government Board on complaint made to them that the council have failed in performing it, and in the case of a rural district by the county council on complaint of the parish council. All sewers, whether made by the council, by their predecessors, or by private persons, vest in the district council—that is to say, become their property, with some exceptions, of which the principal is sewers made by a person for his own profit. The owner or occupier of any premises is entitled as of right to cause his drain to be connected with any sewer, on condition only of his giving notice and complying with the regulations of the council as to the mode in which the communication is to be made, and subject to the control of any person appointed by the council to superintend the work. Moreover, the owner or occupier of premises without the district has the same right, subject only to such terms and conditions as may be agreed or, in case of dispute, settled by justices or by arbitration. If a house does not possess a sufficient drain, the occupier may be required to provide one, and to cause it to discharge into a sewer if there is one within 100 feet of the house, otherwise into a cesspool, as the council may direct. In the case of new houses, these may not be built or occupied in an urban district without their being first provided with sufficient drains as the council may require; and in an urban district it is forbidden to cause any building to be newly erected over a sewer without the consent of the council. For the purpose of sewage disposal a district council may construct any works and contract for the use or purchase or lease of any land, buildings, engines, materials, or apparatus, and contract to supply for a period not exceeding twenty-five years any person with sewage. It may be pointed out here that these expressions are defined by the Act, the effect of the definitions being shortly that a drain is a conduit for the drainage of one building or of several within the same curtilage, while a sewer comprises every kind of drain except that which is covered by the definition of a drain as above stated. The result has been that district councils frequently find themselves in the position of being responsible for the repair and condition of drains which, by reason of having been laid for more than one house, are sewers vested in and repairable by them. An attempt was made to remedy this state of things by the Public Health Amendment

Act, 1890, section 19, but the remedy so provided was very partial, and may be said to be confined to the case where two or more houses belonging to different owners are drained into a common drain laid under private land, and ultimately discharging into a sewer in a road or street.

The district council are charged with the duty of enforcing the provision of proper sanitary accommodation (water-closets, privies, ashpits, &c.) for all dwelling-houses, new or old, and for factories, and the maintenance of such conveniences in proper condition. The urban council have power to provide and maintain and make provision for the regulation of urinals, water-closets, earth-closets, privies, ashpits, and other similar conveniences for public accommodation. In the event of a complaint being made in a district council that any drain, closet, privy, ashpit, or cesspool is a nuisance or injurious to health, the council may empower their surveyor to enter and examine the premises, and, if the complaint is well founded, they may require the owner to do the necessary works. The district council are not bound to undertake the removal of house refuse from premises, or the cleansing of closets, privies, ashpits, and cesspools. They may, however, undertake these duties, and, if the Local Government Board require, they must do so. An urban council and a rural council, if invested with the requisite power by the Local Government Board, may, and when required by order of that Board must, provide for the proper cleansing of streets, and may also provide for the proper watering of streets. When they have undertaken, or are required to perform these duties, a penalty is imposed upon them for neglect. If they do not undertake these duties, they may make bye-laws imposing on the occupiers of premises the duty of cleansing footways and pavements, the removal of house refuse, and the cleansing of earth-closets, privies, ashpits, and cesspools; and an urban council may also make bye-laws for the prevention of nuisances arising from snow, filth, dust, ashes, and rubbish, and for the prevention of the keeping of animals on any premises so as to be injurious to health. The keeping of swine in a dwelling-house, or so as to be a nuisance, is made an offence punishable by a penalty in an urban district, as also is the suffering of any waste or stagnant water to remain in any cellar, or within any dwelling-house after notice, and the allowing of the contents of any closet, privy, or cesspool to overflow or soak therefrom. Provision is also made for enforcing the removal of accumulations of manure, dung soil, or filth from any premises in an urban district, and for the periodical removal of manure or other refuse from mews, stables, or other premises.

With regard to water-supply, district councils have extensive powers. They may provide their district or any part of it with a supply of water proper and sufficient for public and private purposes, and for this purpose they may construct and maintain waterworks, dig wells, take on lease or hire any waterworks, purchase waterworks or water, or right to take or convey water either within or without their district, and any rights, powers, and privileges of any water company, and contract with any person for the supply of water. They may not, however, commence to construct waterworks within the limits of supply of any water company empowered by Act of Parliament or provisional order to supply water without giving notice to the company, and not even then so long as the company are able and willing to supply the necessary water. Any dispute as to whether the company are able and willing has to be settled by arbitration. Where the council do supply water, they have the same powers of carrying mains under streets or through private lands as they have with respect to the laying of sewers, as already mentioned. They can charge water rents which depend upon agreements with consumers, or they may charge water rates assessed on the net annual value of the premises supplied. It is to be observed that they are not bound to charge for a supply of water at all, unless they are required to do so in an urban district by at least ten persons, rated to the poor rate, or in a parish in a rural district by at least five persons so rated in the parish. Even then the amount of the rate is left to the council, any deficiency in the cost of the water, in so far as it is not defrayed out of water rates or rents, being borne in an urban district by the general district rate, and in a rural district by the separate sanitary rates made for the parish or contributory place supplied. For the purpose of enabling them to supply water, most of the provisions of the Waterworks Clauses Acts are incorporated with the Public Health Act, and are made available for the district council. They are empowered to supply water by measure if they think fit, and may charge a rent for water-meters. The power of the district council to supply water is strictly limited to their own district, but they may, with the sanction of the Local Government Board, supply water to the council of an adjoining district on such terms as may be agreed upon, or as, in case of dispute, may be settled by arbitration. If any house is without a sufficient supply, and it appears that a supply can be furnished at a reasonable cost, as defined in the Public Health Act and the Public Health Water-

Sanitary accommodation for houses.

Removal of refuse.

Water-supply.

Committees.

Public Health Acts.

Sewerage and drainage.

Act, 1878, the owner may be required to provide the supply, and, if he fails, the council may themselves provide the supply and charge the owner with the cost. All public sources of water-supply, such as streams, pumps, wells, reservoirs, conduits, aqueducts, and works used for the gratuitous supply of water to the inhabitants of the district are vested in the council, who may cause all such works to be maintained and plentifully supplied with pure and wholesome water for the gratuitous use of the inhabitants, but not for sale by them. The council may supply water to public baths or wash-houses, or for trade or manufacturing purposes. In the case of the former the supply may be gratuitous. In the latter case it is to be on terms agreed between the parties. The urban council are required to cause fire-plugs, and all necessary works, machinery, and assistance for securing a supply of water in case of fire, to be provided and maintained, and for this purpose they may enter into an agreement with any water company or person. Provision is made for preventing the pollution of water by gas refuse and enabling a district council, with the sanction of the Attorney-General, to take any proceedings they may think fit for preventing the pollution of any stream in their district by sewage. The district council are also empowered to obtain an order of justices directing the closing of any well, tank, or cistern, public or private, or any public pump the water from which is likely to be used for drinking or domestic purposes, or for manufacturing drinks for the use of man, if such water is found to be so polluted as to be injurious to health.

Power is given to prohibit the use as dwellings of any cellars, vaults, or underground rooms built or occupied after 1875, and with regard to such cellars as were occupied as dwellings before 1875, the continued occupation of these is also forbidden unless they comply with certain stringent requirements as to the height of the rooms, height of the ceilings above the surface of the street, open areas in front, effectual drainage, sanitary conveniences appurtenant to the cellars, and the provision of fireplaces.

District councils are required to keep a register of the common lodging-houses in their district. No person is allowed to keep a common lodging-house unless he is registered, and a house may not be registered until it has been inspected and approved for the purpose by an officer of the council.

Further, the council may refuse to register a keeper unless he produces a certificate of character in a prescribed form. The council are empowered to make bye-laws for fixing the number of lodgers and separating the sexes therein, promoting cleanliness and ventilation, giving of notices and taking precautions in case of any infectious disease, and generally for the well-ordering of such houses. The keepers of common lodging-houses are required to lime-wash their walls and ceilings in the months of April and October in every year, and if paupers or vagrants are received to lodge, they may be required to report as to the persons who have resorted thereto. They must give notice of any infectious disease to the medical officer of health and to the poor-law relieving officer, and they must give free access for inspection. There is no definition of the expression "common lodging-house" in the Public Health Act, and at one time the courts decided that shelters for the destitute kept by charitable persons were not common lodging-houses. That idea is now exploded, and the Act applies to charitable institutions which receive persons of the class ordinarily received into common lodging-houses.

Bye-laws may also be made relating to houses let in lodgings which are not common lodging-houses. These bye-laws are in practice limited to those inhabited by the poorer classes, although the Act imposes no such restriction.

The Public Health Act, 1875, contains elaborate provisions for dealing with nuisances. Those which are dealt with summarily are thus enumerated:—(1) any premises in such a state

as to be a nuisance or injurious to health; (2) any pool, ditch, gutter, watercourse, privy, urinal, cesspool, drain, or ashpit so foul or in such a state as to be injurious to health; (3) any animal so kept as to be a nuisance or injurious to health; (4) any accumulation or deposit which is a nuisance or injurious to health; (5) any house or part of a house so overcrowded as to be dangerous or injurious to the health of the inmates, whether or not members of the same family; (6) any factory, workshop, or workplace not already under the operation of any general Act for the regulation of factories or bakehouses not kept in a cleanly state or not ventilated in such a manner as to render harmless as far as practicable any gases, vapours, dust, or other impurities generated in the course of the work carried on therein that are a nuisance or injurious to health, or so overcrowded while work is carried on as to be dangerous or injurious to the health of those employed therein; (7) any fireplace or furnace which does not as far as practicable consume the smoke arising from the combustible used therein, and which is used for working engines by steam or in any mill, factory, dye-house, brewery, bakehouse, or gas work, or in any manufacturing or trade process whatsoever, and (8) any chimney not being the chimney of a private dwelling-house

sending forth black smoke in such quantity as to be a nuisance. The nuisances above enumerated are said to be nuisances liable to be dealt with summarily. It is the duty of every district council to inspect their district with a view to the discovery of any such nuisances. In the event of such discovery by them or of information given to them of the existence of any such nuisance, the district council are required to serve a notice requiring the abatement of the nuisance on the person by whose act, default, or sufferance it arises or continues, or, if such person cannot be found, on the owner or occupier of the premises at which the nuisance arises. The notice must require the abatement of the nuisance within a specified time, and must prescribe the works which in the opinion of the council are necessary to be done. If the nuisance arises from the absence or defective construction of any structural convenience, or if there is no occupier of the premises, the notice must be served upon the owner. If the person who causes the nuisance cannot be found, and it is clear that the nuisance does not arise or continue by the act, default, or sufferance of the owner or occupier of the premises, the local authority may themselves abate the nuisance without further order. If the person on whom the notice is served objects to give effect to it, he may be summoned before justices, and the justices may make an order upon him to abate the nuisance or prohibiting the recurrence of the nuisance if this is likely, and directing the execution of the necessary works. If the nuisance is such as to render a dwelling-house unfit for human habitation, the justices may close it until it is rendered fit for that purpose. Disobedience under the order of justices involves a penalty and a daily penalty for every day during which default continues. Private persons may complain to justices in respect of nuisances by which they are personally aggrieved, and if the district council make default in doing their duty, the Local Government Board may authorize any officer of police to institute any necessary proceedings at the cost of the defaulting council. The district council may, if in their opinion proceedings before justices afford an inadequate remedy, take proceedings in the high court, but in that case, if the nuisance is of a public nature, they must proceed by action in the name of the Attorney-General. The provisions as to nuisances are extended to ships by an Act of 1885.

It is forbidden to establish within an urban district without the consent of the council any offensive trade, business, or manufacture. With regard to any offensive trade which has been established or may be consented to in any urban district, if it is verified by the medical officer or any two legally qualified medical practitioners, or by any ten inhabitants of the district, to be a nuisance or injurious to health, the urban district council are required to take proceedings before magistrates with a view to the abatement of the nuisance complained of.

Any medical officer or inspector of nuisances may inspect any meat, &c., exposed for sale or deposited in any place for the purpose of sale or of preparation for sale and intended for the food of man. This power of inspection is, in districts where the Public Health Act, 1890, has been adopted, extended to all articles intended for the food of man. If upon such inspection the meat, &c., appears to be diseased, unsound, or unwholesome, it may be taken before a justice for the purpose of being condemned, and the person to whom the meat, &c., belongs or in whose possession it was found is liable to a penalty or, in the discretion of the justices, to imprisonment for three months without the option of a fine.

The Public Health Acts contain important provisions relating to infectious disease. Local authorities may require premises to be cleaned and disinfected; they may order the destruction of bedding, clothing, or other articles which have been exposed to infection; they may provide proper places for the disinfection of infected articles free of charge; they may provide ambulances, &c. In the case of a person found suffering from infectious disease who has not proper lodging or accommodation, or is lodging in a room occupied by more than one family, or is on board any ship or vessel, such person may by means of a justice's order be removed to a hospital; and any person exposing himself or any other in his charge while suffering from infectious disease, or exposing infected bedding, clothing, or the like, is made liable to a penalty. Owners and drivers of public conveyances used for the carriage of persons suffering from infectious disease are required to disinfect them; but any person who enters a public conveyance while so suffering or takes an infected person into it without notifying the fact to the driver is liable to a penalty. It is also forbidden to let houses or rooms in which infected persons have been lodging, or to make false statements to persons negotiating for the hire of such rooms. An Act was passed in the year 1890, called the Infectious Diseases Prevention Act, which may be adopted by any local authority. When adopted it enables an urban or district council to obtain the inspection of dairies where these are suspected to be the cause of infectious disease, with a view to prohibiting the supply of milk from such dairies if the fact is established. The Act also forbids the keeping for more than forty-eight hours of the body of a person who has

died of infectious disease in a room used at the time as a dwelling-place, sleeping-place, or workshop. It provides for the bodies of persons dying of infectious diseases in a hospital being removed only for burial, and gives power to justices in certain cases to order bodies to be buried. The diseases to which the Act applies are smallpox, cholera, membranous croup, erysipelas, scarlatina or scarlet fever, typhus, typhoid, enteric, relapsing, continued or puerperal fever, and any other infectious disease to which the Act has been applied by the local authority of the district in the prescribed manner. The most important provision, however, relating to infectious disease is that contained in the Infectious Disease Notification Act, 1889. That was originally an adoptive Act, but it is now extended to all districts in England and Wales. It requires the notification to the medical officer of health of the district of every case in which a person is suffering from one of the diseases above mentioned. The duty of notification is imposed upon the head of the family, and also upon the medical practitioner who may be in attendance on the patient. The medical attendant is entitled to receive in respect of each notification a fee of 2s. 6d. if the case occurs in his private practice, and of 1s. if the case occurs in his practice as medical officer of any public body or institution. These fees are paid by the urban or rural district council as the case may be. The provisions as to notification are applied to every ship, vessel, boat, tent, van, shed, or similar structure used for human habitation in like manner as nearly as may be as if it were a building. Exception is made, however, in the case of a ship, vessel, or boat belonging to a foreign government. It is not too much to say that this Act has been one of the most effectual means of preventing the spread of infectious disease in modern times.

The district council are empowered to provide hospitals or temporary places for the reception of the sick. They may build them, contract for the use of them, agree for the reception of the sick inhabitants of their district into an existing hospital, or combine with any other district council in providing a common hospital. As has already been mentioned when dealing with county councils, if a district council make default in providing hospital accommodation, the county council may put in operation the Isolation Hospitals Act. The power given to provide hospitals must be exercised so as not to create a nuisance, and much litigation has taken place in respect of the providing of hospitals for smallpox. Up to the present time, however, the courts have refused to accept as a principle that a smallpox hospital is necessarily a source of danger to the neighbourhood, and for the most part applications for injunction on that ground have failed.

Where any part of the country appears to be threatened with or is affected by any formidable epidemic, endemic, or infectious disease, the Local Government Board may make regulations for the speedy interment of the dead, house-to-house visitation, the provision of medical aid and accommodation, the promotion of cleansing, ventilation, and disinfection, and the guarding against the spread of disease. Such regulations are made and enforced by the district councils. The provisions of the Public Health Acts relating to infectious disease are for the most part extended to ships by an Act of the year 1885.

District councils may and, if required by the Local Government Board, are required to provide mortuaries, and they may make bye-laws with respect to the management and charges for the use of the same. Where the body of a person who has died of an infectious disease is retained in a room where persons live or sleep, or the retention of any dead body may endanger health, any justice on the certificate of a medical practitioner may order the removal of the body to a mortuary and direct the body to be buried within a time limited by the friends of the deceased or in their default by the relieving officer. A district council may also provide and maintain a proper place (otherwise than at a workhouse or at a mortuary) for the reception of dead bodies during the time required to conduct any *post mortem* examination ordered by a coroner.

Under an Act of 1879 the district council have power to provide and maintain a cemetery either within or without their district, and they may purchase or accept a donation of land for that purpose. The provisions of the Cemeteries Clauses Act, 1847, apply to a cemetery thus provided. These cannot all be referred to here, but it may be noted that no part of the cemetery need be consecrated, but that if any part is, such part is to be defined by suitable marks, and a chapel in connexion with the Established Church must be erected in it. A chaplain must also be appointed to officiate at burials in the consecrated portion. The power to provide a cemetery under the Act under consideration must not be confounded with that of providing a burial ground under the Burial Acts. These Acts will be mentioned later in connexion with the powers of parish councils, for in general they are adopted for a parish, part of a parish, or combination of parishes, and are administered by a burial board, except where that body has been superseded by a parish council or joint committee. It may be mentioned, however, that under the Local Government Act, 1894,

where a burial board district is wholly in an urban district, the urban council may resolve that the powers, duties, and liabilities of the burial board shall be transferred to the council, and thereupon the burial board may cease to exist. And it is provided by the same Act that the Burial Acts shall not hereafter be adopted in any urban parish without the approval of the urban council. The distinction between a burial ground provided under the Burial Acts and a cemetery provided under the Act of 1879 is important in many ways, of which one only need be mentioned here—the expenses under the Burial Acts are paid out of the poor rate, while the expenses under the Act of 1879 are paid in an urban district out of the general district rate, the incidence of which differs materially from that of the poor rate, as will be seen hereafter.

In an urban district the urban council have always had all the powers and duties of a surveyor of highways under the Highway Acts. But before 1894 a rural district council had no power or duty in respect of highways except in a few cases where, by virtue of a provision in the Highway Act, 1878, the rural sanitary authority of a district coincident in area with a highway district were empowered to exercise all the powers of a highway board. Except in these cases the highway authority in a parish was the surveyor of highways, elected annually by the inhabitants in vestry, or in a highway district consisting of a number of parishes united by order of quarter sessions, the highway board composed of waywardens representing the several parishes. By the Local Government Act, 1894, there were transferred to the district council of every rural district all the powers, duties, and liabilities of every highway authority, surveyor, or highway board within their district, and the former highway authorities ceased to exist. The highway authority in every district, rural as well as urban, is therefore the district council. Of the chief duties of a district council with regard to highways, the first and most obvious is the duty to repair. This duty was formerly enforceable by indictment of the inhabitants of the parish, but it is not quite clear whether this procedure is applicable, now that the liability to repair is transferred to a council representing a wider area. Under the Highway Acts it is enforceable by summary proceedings before justices and by orders of the county council, but in either case, if the liability to repair is disputed, that question has to be decided on indictment preferred against the highway authority alleged to be in default. In a rural district any parish council may complain to the county council that the district council have made default in keeping any highway in repair, and the county council may thereupon transfer to themselves and execute the powers of the district council at the cost of the latter body, or they may make an order requiring the district council to perform their duty, or they may appoint some person to do so at the cost of the district council. It is important to observe, however, that an action does not lie against a district council in respect of the failure to repair a highway even at the suit of a person who has thereby been injured. The reason assigned for this doctrine is that the council as highway surveyor stand in the same position as the inhabitants of the parish, against whom such an action would not lie. The district council are, however, liable for any injury caused through negligence on the part of their officers or servants in carrying out the work of repair.

But while rural as well as urban district councils have the powers and duties of surveyors of highways, the provisions of the Public Health Acts relating to streets apply only in urban districts, except in so far as the Local Government Board may by order have conferred urban powers upon a rural district council. These provisions have now to be referred to. It may be convenient to state that the expression "street" is here used in a sense much wider than its ordinary meaning. It is defined by the Act to include any highway and any public bridge (not being a county bridge), and any road, lane, footway, square, court, alley, or passage, whether a thoroughfare or not. For certain purposes streets as thus defined are divided into two classes, viz., those which are and those which are not highways repairable by the inhabitants at large. But it has to be borne in mind that it is not every highway that is repairable by the inhabitants at large. Before the year 1836 as soon as a way was dedicated to public use and the public had by user signified their acceptance of it, it became without more notice repairable by the parish. Therefore every highway—whether carriage-way, driftway, bridleway, or footway—which can be shown to have been in use before 1836, is presumably repairable by the inhabitants at large, the only exceptions being such highways as are repairable by private persons or corporate bodies *ratione clausuræ, ratione tenuræ*, or by prescription. But in the year 1836, when the Highway Act, 1835, came into operation, the law was altered. It was possible, just as formerly, to dedicate a way to the use of the public, and it thereupon became a highway to all intents and purposes. But mere dedication did not make the way repairable by the public. That result was not to follow unless certain stringent requirements were fulfilled. When it is shown, therefore, that a highway has been dedicated after 1836, it is not repairable by the inhabitants at large unless

it can be shown that these provisions have been complied with, or that it has been declared to be repairable under provisions of the Public Health Acts presently to be mentioned. (There was also power given to justices by the Highway Act, 1862, to declare a private road or occupation road in a highway district to be a public highway repairable by the parish; but this power does not appear to have been acted upon to any extent.)

All streets being highways repairable by the inhabitants at large within an urban district, are vested in and under the control of the urban council. After much litigation it has now been established that this provision does not give the council an absolute property in the soil of the street, but merely such a qualified property in the surfaces as enables them to exercise control. The urban council are required from time to time to cause all such streets to be made up and repaired as occasion may require, and they are empowered to raise, lower, or alter the soil of the street, and to place and keep in repair fences and posts for the safety of foot-passengers. The other class of streets consists of those which are not highways repairable by the inhabitants at large. Under the Public Health Act, 1875, such streets may be dealt with in manner following:—If any such street or part thereof is not sewered, levelled, paved, metalled, flagged, channelled, made good, or lighted to the satisfaction of the council, the council may cause it to be made up at the expense of the owners of premises fronting the street in proportion to their several frontages. When all or any of the works aforesaid have been executed in the street, and the council are of opinion that the street ought to become a highway repairable by the inhabitants at large, they may by notice to be fixed up in the street declare it to be a highway repairable by the inhabitants at large, and the declaration will be effective unless, within one month after the notice has been put up, the majority of the owners in the street object thereto. An alternative procedure has been provided by the Private Street Works Act, which may be adopted by any urban council. One important point of difference is that under the latter Act the council may resolve that the expenses shall be apportioned among the owners not merely according to frontage, but according to the greater or less degree of benefit to be derived by any premises from the works.

Where a house or building in a street is taken down to be rebuilt, the urban district council may prescribe the line to which it is to be rebuilt, paying compensation to the building owner for any damage which he may sustain consequent upon the requirement. Save to this extent, no power is given by the general law to a district council to prescribe a building line. But under an Act of 1888 it is provided that it shall not be lawful in any urban district without the consent of the urban authority to erect or bring forward any house or building in any street or any part of such house or building beyond the front main wall of the house or building on either side thereof in the same street.

The control exercised by an urban district council over streets and buildings is to a very large extent exercised through bye-laws which they are empowered to make for various purposes relating to the laying out and formation of new streets, the erection and construction of new buildings, the provision of sufficient air-space about buildings to secure a free circulation of air, and the provision of suitable and sufficient sanitary conveniences. The manner in which such bye-laws are made and confirmed will be hereafter noticed. In general, the bye-laws require plans of new streets to be submitted to the council, and they are required to approve or disapprove of these plans within a month. They cannot disapprove of a plan unless it contravenes the provisions of some statute or bye-law; but if a person builds otherwise than according to an approved plan he does so at the risk of having his work pulled down or destroyed. Among the miscellaneous powers of an urban council with respect to streets may be mentioned the power to widen or improve, and certain powers incorporated from the Towns Improvement Clauses Act, 1847, with respect to naming streets, numbering houses, improving the line of streets, removing obstructions, providing protection in respect of ruinous or dangerous buildings, and requiring precautions to be taken during the construction and repair of sewers, streets, and houses. An urban council may also provide for the lighting of any street in their district, and may contract with any person or company for that purpose. If there is no company having statutory powers of supply within their district, they may themselves undertake the supply of gas, and they may purchase the undertaking of any gas company within their district.

An urban council may acquire and maintain lands for the purpose of being used as public walks or pleasure-grounds, and may support or contribute to the support of such walks or grounds if provided by any other person. They may also contribute to the cost of laying out, planting, or improvement of lands provided for this purpose by any person, in their own district or outside that district, if it appears that the walks or grounds could eventually be used by the inhabitants of that district. An urban council may also provide public clocks or pay for the reasonable cost of repairing and maintaining any public clocks in the district, though not vested in them.

Public parks.

Where an urban council are the council of a borough, and in other cases with the consent of the owners and ratepayers of the district, they may provide market accommodation for their district. They may not, however, establish any market so as to interfere with any market already established in the district under a franchise or charter. For purposes of markets certain provisions of the Markets and Fairs Clauses Act, 1847, are incorporated with the Public Health Act. The only one of these that need be noticed is that which provides that after the market is opened for public use every person, other than a licensed hawk, who shall sell or expose for sale in any place within the district, except in his own dwelling-place or shop, any articles in respect of which tolls are authorized to be taken shall be liable to a penalty. The tolls which may be taken by an urban council must be approved by the Local Government Board; and any bye-laws which they make for the regulation of the market must be confirmed by the same body. An urban council may also provide slaughter-houses and make bye-laws with respect to the management and charges for the use of them. Where they do not provide slaughter-houses, all previously existing slaughter-houses have to be registered and new ones licensed; and no person may lawfully use a slaughter-house which is not either registered or licensed. Licences may be suspended by justices in the event of their being used contrary to the provisions of the Act or of the bye-laws, and on a second conviction the licence may be revoked. On a conviction of selling or exposing for sale, or having in his possession or on his premises, unsound meat, the court may also revoke the licence.

Markets and slaughter-houses.

Certain police regulations contained in the Town Police Clauses Act, 1847, are by virtue of the Public Health Act, 1875, in force in all urban districts. These relate to obstructions and nuisances in streets, fires, places of public resort, hackney carriages, and public bathing. An urban council may also license proprietors, drivers, and conductors of horses, ponies, mules, or asses standing for hiring in the district in the same way as in the case of hackney carriages, and they may also license pleasure-boats and vessels, and the boatmen or persons in charge thereof, and they may make bye-laws for all these purposes.

Hackney carriages, &c.

Every district council may enter into such contracts as are necessary for carrying into execution the various purposes of the Public Health Acts. A district council being a corporation, the general law applies in the case of a rural council that they must contract under their common seal, the exception to this rule including the doing of acts very frequently recurring or too insignificant to be worth the trouble of affixing the common seal. In the case of an urban council certain stringent regulations are laid down. A contract made by an urban council, whereof the value and amount exceed £50, must be under seal, and certain other formalities must be observed, some of which are imperative; for example, the taking of sureties from the contractor, and the making provision for penalties to be paid by him in case the terms of the contract are not observed. Every local authority may also, for purposes of the Act, purchase or take on lease, sell or exchange, any lands. Such lands as are not required for the purpose for which they were purchased must, unless the Local Government Board otherwise direct, be sold. Powers of compulsory purchase of lands are also given under the Lands Clauses Acts, but before these can be put in operation certain conditions must be observed. The Local Government Board must make inquiry into the propriety of allowing the lands to be taken, and the power to acquire the lands compulsorily can only be conferred by means of a provisional order confirmed by Parliament.

Contracts, purchase of lands.

With regard to the bye-laws which district councils may make for many purposes, the subjects of which have been already from time to time mentioned, it is only necessary to state that these require to be confirmed by the Local Government Board. Such confirmation does not, however, give validity to a bye-law which cannot be justified by the provisions of the Act, and many bye-laws which have been so confirmed have been held to be invalid under the general law as being uncertain, unreasonable, or repugnant to the law of the realm. For the guidance of local authorities, the Local Government Board have from time to time issued model series of bye-laws dealing with the various subjects for which bye-laws may be made, and these are for the most part followed throughout England and Wales.

Bye-laws.

As a general rule, all the expenses of carrying into execution the Public Health Acts in an urban district fall upon a fund which is called the general district fund, and that fund is provided by means of a rate called the general district rate. To this there are some exceptions. First, in the case of boroughs where from the time of the first adoption of the Sanitary Acts these expenses have been paid out of the borough rate, the expenses continue to be so paid; and in an urban district which was formerly subject to an Improvement Act, the expenses may be payable out of the improvement rate authorized by that Act. The

Finance.

general rule, however, prevails over by far the greater part of England and Wales. The general district rate is made and levied on the occupiers of all kinds of property for the time being assessable to any rate for the relief of the poor, subject to a few exceptions and conditions. Of these the first is that the owner may be rated instead of the occupier, at the option of the urban authority, where the value of the premises is under £10, where the premises are let to weekly or monthly tenants, or where the premises are let in separate apartments, or the rents become payable or are collected at any shorter period than quarterly. When the owner is rated he must be assessed upon a certain proportion only of the net annual value of the premises. The owners or occupiers of certain specified properties are assessed in respect of the same in the proportion of one-fourth part only of the net annual value thereof. These properties include tithes, tithes commutation rent charge, land used as arable, meadow or pasture ground only, or as woodlands, market gardens or nursery grounds, orchards, allotments, any land covered with water such as the reservoir of a waterworks company, or used only as a canal or towing-path of the same, or as a railway constructed under the powers of any Act of Parliament for public conveyance. The reason for these partial exemptions apparently is that sanitary arrangements are made chiefly for the benefit of houses and buildings, while the properties just enumerated do not receive the same amount of benefit. The only other point to be noticed in this connexion is that an urban council may divide their district into parts for all or any of the purposes of the Act, rating each part separately for those purposes. The expenses of highways in an urban district fall as a rule upon the general district rate, but under certain conditions, which need not be here set out, a separate highway rate may have to be levied. The urban council have extensive powers of amending the rate, and the rate is collected in such manner as the urban authority may appoint.

The expenses of a rural district council are of two kinds. Of these the first is called general expenses, and it includes the expense of the establishment and officers of the council, of disinfection, providing of conveyance for infected persons, and the expenses of highways. These expenses are payable out of a common fund which is raised out of the poor rate of the several parishes in the district, according to the rateable value of each. Special expenses include the expenses of the construction and maintenance and cleansing of sewers, providing water supply, and all other expenses incurred or payable in respect of a parish or contributory place within the district determined by order of the Local Government Board to be special expenses. The expression "contributory place" means a place other than a parish chargeable with special expenses. For the most part it has reference only to what is called a special drainage district—that is to say, a district formed out of one or more parishes or parts of parishes for the purpose of the provision of a common water supply, or scheme of sewerage, or the like, and in the event of such a district including part only of a parish, the remaining portion would, so far as the special expenses for which the district was created are concerned, be a separate contributory place. These special expenses are chargeable to each parish or contributory place, and they are defrayed by means of special sanitary rates, such rates being raised on all property assessed to the relief of the poor, but with the same exemptions of certain properties as have been mentioned under the head of general district rate in urban districts.

District councils are empowered to borrow with the sanction of the Local Government Board, subject to certain restrictions and regulations. The money must be borrowed for permanent works, the expenses of which ought in the opinion of the Local Government Board to be spread over a term of years which must not exceed sixty. The sums borrowed must not exceed, with the outstanding loans, the amount of the assessable value for two years of the district for which the money is borrowed; and if the sum borrowed would, with the outstanding loans, exceed the assessable value for one year, the sanction of the Local Government Board may not be given except after local inquiry. The money may be repaid by equal instalments of principal, or of principal and interest, or by means of a sinking fund.

Where the urban council are the council of a borough, their accounts as urban council are made up and audited in the same ineffective manner as has already been mentioned in the case of the accounts of the council under the Municipal Corporations Act, but each of the borough auditors receives remuneration for auditing the accounts of the council as urban district council. Where the urban council are not the council of a borough, the accounts are made up annually, and audited by the district auditor in the same effective manner as has already been mentioned in the case of the accounts of a county council. The accounts of a rural district council are made up half-yearly, and are audited in the same way.

The Public Authorities Protection Act, 1893, was passed to repeal the numerous provisions contained in many Acts of Parliament, whereby, before legal proceedings could be taken against a

public body, notice of action had to be given and the proceedings commenced within a certain limited time. The Act applies to all public authorities, including, of course, district councils, and it provides in effect that where any action or legal proceeding is taken against a council for any act done in pursuance of execution, or intended execution, of an Act of Parliament, or of any public duty or authority, the action must be commenced within six months next after the act, neglect, or default complained of, or in the case of a continuance of injury or damage, within six months next after the ceasing thereof. And it provides further that, in the event of the judgment of the court being given in favour of the council, the council shall be entitled to recover their costs taxed as between solicitor and client. Notice of action is abolished in every case.

Proceedings against district councils.

Among other Acts which are either incorporated with the Public Health Acts or have been passed subsequently to them, one of the most important is the Housing of the Working Classes Act, 1890. It contains three distinct parts. Under the first an urban district council may, by means of a scheme, acquire, rearrange, and reconstruct an area which has been proved to be insanitary. The scheme has to be confirmed by the Local Government Board, and carried out by means of a provisional order. The second part of the Act deals with unhealthy dwelling-houses, and requires the urban district council to take steps for the closing of any dwelling-houses within their district which are unfit for human habitation. The third part of the Act deals with what is called in the Act working-class lodging-houses. But the expression is a little misleading, for it includes separate houses or cottages for the working classes, whether containing one or several tenements, and the expression "cottage" may include a garden of not more than half an acre, provided that the estimated annual value of such garden shall not exceed £3. This part of the Act may be adopted by a rural district council, but an urban district council can carry it into execution without formal adoption. Land may be acquired for erecting lodging-houses as above defined, and these, when erected, may be managed and let by the council.

Housing of the working classes.

The urban district council may adopt the provisions of the Baths and Washhouses Acts, and thereunder provide public baths, wash-houses, open bathing-places, covered swimming baths, which they may close in the winter months and use as gymnasias.

Baths and wash-houses.

Under the Tramways Act, 1870, the urban district council may obtain from the Board of Trade a provisional order authorizing the construction of tramways in their district by themselves. Any private persons, and any corporation or company, may, with the consent of the council, obtain the like authority, but the Board of Trade have power in certain cases to dispense with the consent of the local authority. Where the order is obtained by a person or body other than the district council, the council may purchase the undertaking at the end of twenty-one years after the tramways have been constructed or at the expiration of every subsequent period of seven years, and the terms of purchase are that the person or company must sell the undertaking upon payment of the then value, exclusive of any allowance for past or future profits of the undertaking, or any compensation for compulsory sale or other consideration whatsoever of the tramway, and all lands, buildings, works, materials, and plant suitable to and used for the purposes of the undertaking. It should be observed, however, that although the local authority may themselves construct, and may acquire from the original promoters, a system of tramways, they may not themselves work them without special authority of the legislature, and must in general let the working of the undertaking to some person or company.

Tramways.

Under the Borough Funds Act, 1872, the urban district council may, if in their judgment it is expedient, promote or oppose any local and personal Bill or Bills in Parliament, or may prosecute or defend any legal proceedings necessary for the promotion or protection of the interests of the district, and may charge the costs incurred in so doing to the rates under their control. The power to incur parliamentary costs, however, is subject to several important restrictions. The resolution to promote or oppose the Bill must in the first instance have been carried by an absolute majority of the whole number of the council at a meeting convened by special notice, and afterwards confirmed by the like majority. The resolution must have been published in newspapers circulated in the district, and must have received the consent of the Local Government Board or of a Secretary of State, if the matter is one within its jurisdiction; and further, the expenses must not be incurred unless the promotion or opposition has been assented to by the owners and ratepayers of the district assembled at a meeting convened for the purpose of considering the matter, and if necessary, signified by a poll. Moreover, the expenses must, before they can be charged to the rates, be examined and allowed by some person authorized by a Secretary of State or the Local Government Board, as the case may be.

Bills in Parliament and legal proceedings.

Under the Pawnbrokers Act, 1872, the licences to pawnbrokers, which were formerly granted by justices, are now granted by district councils.

Under the Sale of Food and Drugs Acts certain important duties devolve upon medical officers and inspectors of nuisances who are officers of district councils. But for the most part the

Adulteration. Acts do not impose upon district councils themselves any special powers or duties, although, as a matter of fact, prosecutions for offences are usually undertaken by the district councils, and the expenses of the execution of the Acts are paid out of their funds. In quarter sessions boroughs, however, where the council have the duty of appointing a public analyst, they are under an obligation to put the Acts in force from time to time, as occasion may arise. The Acts themselves must be consulted for the procedure, beginning with the taking of samples and ending with the conviction of an offender.

The powers and duties of a district council under the Rivers Pollution Prevention Act, 1876, have been incidentally noticed when dealing with county councils, whose powers under the Acts are precisely the same.

Rivers pollution. Under the Electric Lighting Acts the Board of Trade may license any district council to supply electricity, or may grant to them a provisional order for the same purpose. A similar licence or order may be granted to a private person or company to supply electricity within the district of a district council, but in that case the consent of the district council must be given, unless the Board of Trade, for special reasons, dispense with such consent. These licences are now rarely applied for or granted, and the provisions which were formerly contained in the provisional orders have now been consolidated by the Electric Lighting Clauses Act, 1899, the effect of which will be to make provisional orders uniform for the future. It is now almost the exception, at least in urban districts, to find a district council which has not obtained a provisional order under these Acts, and for the most part the undertakings of local authorities in the way of supplying electricity have been very prosperous.

Under the Allotments Acts district councils are empowered to provide allotments for the labouring population of their district, if they are satisfied that there is a demand for allotments, that these cannot be obtained at a reasonable rent by voluntary arrangement, and that the land can be let at such a price as will not involve a loss to the council. The district council may acquire land, let it and regulate it, and they may, in certain cases, provide common pasture.

Allotments. The urban district council execute the Public Libraries Acts for their district, and the rate for the expenses of the Acts, which may not exceed 1d. in the £, is in a borough in the nature of a borough rate, and in any other urban district in the nature of a general district rate. Under the Acts not only public libraries, but also public museums, schools for science, art galleries, and schools for art, with the necessary buildings, furniture, fittings, and conveniences, may be provided for the inhabitants of the district. Land may be acquired, and money borrowed, for the purposes of the Acts.

Public libraries. A great number of other statutes confer powers or impose duties upon district councils, such as the Acts relating to town gardens, agricultural gangs, fairs, petroleum, infant life protection, commons, open spaces, canal boats, factories and workshops, margarine, sale of horse-flesh, and shop hours.

Before the passing of the Local Government Act, 1894, there was really nothing in the form of local government for a parish. It is true that the inhabitants in vestry had certain powers. They

The parish and the parish council. could adopt various Acts, which will be more particularly referred to hereafter, and they could appoint the persons who were to carry these Acts into execution. They elected the churchwardens and overseers, the highway surveyor, if the parish was a separate unit for highway purposes, and the waywardens if it was included in a highway district. But there was nothing in the nature of a representative body exercising any powers of government in the parish regarded as a separate area. Under the Act of 1894 this was changed. In every rural parish, that is to say, in every parish which is not included within an urban district, there is a parish meeting, which consists of the parochial electors of the parish. As already stated, these are the persons whose names are on the parliamentary and local government registers. If the parish has a population exceeding 300, a parish council must be elected. If it has a population of 100 or upwards, the county council are bound to make an

order for the election of a parish council if the parish meeting so resolves. Where there is no parish council, as will be seen hereafter, the various powers conferred upon a council are exercised by the parish meeting itself. Two or more parishes may be grouped together under a common parish council by order of the county council if the parish meetings of each parish consent. An annual parish meeting in every rural parish must be held on the 25th day of March or within seven days before or after that date; and if there is no parish council, there must be at least one other parish meeting in the year. At the annual parish meeting the parish council, if there is one, is elected, and the members of the council, who originally held office for one year only, now, under a subsequent Act, hold office for three years. Any person who is a parochial elector, or who has for twelve months preceding the election resided in the parish, or within three miles thereof, may be elected parish councillor, and the number of councillors is to be fixed from time to time by the county council, not being less than five nor more than fifteen. Women, whether married or single, are eligible.

The council are elected in manner provided by the rules of the Local Government Board. The rules now in force will be found in the *Statutory Rules and Orders* for 1898, p. 692. They are very similar to those which are in force with reference to the elections of district councils, which have already been noticed. If a poll is demanded, it must be taken under the Ballot Act, as applied by the Rules, and for all practical purposes it may be taken that the election proceeds in the same manner as that of a district council. The parish council elects a chairman annually. He may be one of their own number, or some other person qualified to be a parish councillor. The council is a body corporate, may hold land in mortmain, and can appoint committees for its own parish or jointly with any other parish council. Among the powers conferred upon a parish council are those of appointing overseers and of appointing and revoking the appointment of assistant overseers. In future, churchwardens are no longer to be overseers, and the parish council may appoint as overseers a number of persons equal to the number formerly appointed as overseers and churchwardens. It may be useful to mention here that for purposes of the administration of the poor law, overseers no longer act, their duties in that respect having been superseded by the guardians. They remain, however, the rating authority so far as regards the poor rate and nearly all other rates, the exceptions being the general district rate in an urban district and the borough rate in a borough, made by the town council. They still have power to give relief to poor persons in case of sudden and urgent necessity, but their principal duty is that of rating authority, and they are bound to make out the lists for their parishes of jurors and electors. No payment is made to them. The office is compulsory, but certain persons are privileged from being elected to it. The assistant overseer, who was formerly nominated by the inhabitants and vestry and then formally appointed by justices, is now, as has been stated, appointed by the parish council. He holds office at pleasure, and receives such remuneration as the council fix, and he performs all the duties of an overseer, or such of them as may be prescribed by the terms of his appointment. There may be in a parish a collector of rates appointed by the guardians. In that event, an assistant overseer cannot be appointed to perform the duties of collector of rates, but, on the other hand, the parish council may invest the collector with any of the powers of an overseer. The parish council may appoint a clerk, who may be either one of their own number without payment, or the assistant overseer, rate collector, or some other fit person, with remuneration.

Among the duties transferred to parish councils may be mentioned the provision of parish books and of a vestry room or parochial office, parish chest, fire engine or fire escape, the holding or management of parish property, other than property relating to affairs of the church or held for an ecclesiastical charity, the holding or management of village greens or of allotments, the appointment of trustees of parochial charities other than ecclesiastical charities in certain cases, and certain limited powers with reference to the supply of water to the parish, the removal of nuisances, and the acquisition of rights of way which are beneficial to the inhabitants.

Among the most important of the matters which concern a rural parish is the administration of what are commonly called the adoptive Acts. These include the Lighting and Watching Act, the Baths and Washhouses Acts, the Burial Acts, the Public Improvement Act, and the Public Libraries Acts. The Lighting

Powers to appoint overseers.

Powers and duties of parish councils.

and Watching Act was formerly adopted for a parish, or part of a parish, by the inhabitants in vestry, who elected lighting inspectors, of whom one-third went out of office in every year. The inspectors took the necessary steps for having the parish lighted (the provisions as to watching having been obsolete for many years), and the expenses of lighting were raised by the overseers upon an order issued to them by the inspectors. The owners and occupiers of houses, buildings, and property, other than land, pay a rate in the £ three times greater than that at which the owners and occupiers of land are rated and pay for the purposes of the Act. Now this Act, like the other adoptive Acts, can only be adopted by the parish meeting, and where adopted for part only of a parish, must be adopted by a parish meeting held for that part. After the adoption of the Act, it is carried into execution by the parish council, if there is one, and if not, by the parish meeting, and the expenses are raised in the same manner as heretofore.

Lighting and Watching Act.

Baths and Wash-houses Acts.

The Baths and Washhouses Acts have already been referred to in dealing with district councils, and it is sufficient to say that they are now adopted and administered in a rural parish in the manner pointed out with reference to the Lighting and Watching Act. The same may be said of the Burial Acts, but these are sufficiently important to require special notice. These Acts contain provisions whereby burials may be prohibited in urban districts, and churchyards or burial grounds already existing may be closed when full. Formerly, when the Acts had been adopted by the vestry, it was necessary to appoint a burial board to carry the Acts into execution and provide and manage burial grounds. Now, in a rural parish which is co-extensive with an area for which the Acts have been adopted, the burial board is abolished and the Acts are administered by the parish council; and the Acts cannot be adopted in a rural parish save by the parish meeting. If the area under a burial board in 1894 was partly in a rural parish and partly in an urban district, the burial board was superseded, and the powers of the board are exercised by a joint committee appointed partly by the urban district council and partly by the parish council, or parish meeting, as the case may be. In a rural parish where there is no parish council, though the Acts are adopted by the parish meeting, it is still necessary to elect the burial board, and that board will be elected by the parish meeting. The distinction between a burial ground under the Burial Acts and a cemetery provided under the Public Health Acts has already been noticed. A burial ground, properly so called, has to be divided into consecrated and unconsecrated portions, and the former really takes the place of the parish churchyard; and the incumbent of the parish church, the clerk, and the sexton continue to receive the same fees upon burials in the consecrated portion as they would have done in the parish churchyard. It has been mentioned that a portion of the burial ground must be left unconsecrated. But this is subject to one important exception, that the parish meeting may unanimously resolve that the whole of the burial ground shall be consecrated. In that case, however, the parish council may, within ten years thereafter, determine that a separate unconsecrated burial ground shall also be provided for the parish. The expenses of the execution of the Burial Acts are provided by the overseers out of the poor rate upon the certificate of the body entrusted with the execution of them. In the event of the Acts being adopted for a portion only of a rural parish, the burial board, or the parish meeting, may by resolution transfer all the powers of the board to the parish council.

The Public Improvement Act, when adopted, enables a parish council to purchase or lease, or accept gifts of land for the purpose of forming public walks, exercise or play grounds, and to provide for the expense by means of a parish improvement rate. Before any such rate is imposed, however, a sum in amount not less than at least half of the estimated cost of the proposed improvement must have been raised by private subscription or donation, and the rate must not exceed sixpence in the £.

The Public Libraries Acts enable the authority adopting them to provide public libraries, museums, schools for science, art galleries, and schools for art. The expenses in a rural parish are defrayed by means of a rate raised with, and as part of, the poor rate, with a qualification to the effect that agricultural land, market gardens, and nursery grounds are to be assessed to the rate at one-third only of their rateable value.

The expenses of a parish council may not, without the consent of a parish meeting, exceed the amount of a rate of threepence in the £ for the financial year; but with the consent of the parish meeting the limit may be increased to sixpence, exclusive of expenses under the adoptive Acts. If it is necessary to borrow, the consent of the parish meeting and of the county council must be obtained.

The expenses are payable out of the poor rate by the overseers on the precept of the parish council.

One of the most important powers conferred upon a parish council is that which enables them to prevent stoppage or diversion of any public right of way without their consent and without the approval of the parish meeting. The council may also complain to the county council that the district council have failed to sewer their parish or provide a proper water supply, or generally to enforce the provisions of the Burial Acts; and upon such complaint, if ascertained to be well founded, the county council may transfer to themselves the powers and duties of the district council, or may appoint a competent person to perform such powers and duties. In a parish which is not sufficiently large to have a parish council, most of the powers and duties conferred or imposed on the parish council are exercised by the parish meeting. It may be convenient here to add that where, under the Local Government Act, 1894, the powers of a parish council are not already possessed by an urban district council, the Local Government Board may by order confer such powers on the urban council. This has been done almost universally, as far as regards the power to appoint overseers and assistant overseers, and in many cases urban councils have also obtained powers to appoint trustees of parochial charities.

The foregoing is a sketch of the scheme of local government carried out in England and Wales. No attempt has been made to deal with poor law (*q.v.*) or education (*q.v.*). The local administration of justice devolving upon the justices in quarter or petty sessions is hardly a matter of local government, although in one important respect, that, namely, of the licensing of premises for the sale of intoxicating liquors, it may be thought that the duties of justices fall within the scope of local government. It will be seen that the scheme, as at present existing, has for its object the simplification of local government by the abolition of unnecessary independent authorities, and that this has been carried out almost completely, the principal exception being that in some cases burial boards still exist which have not been superseded either by urban district councils or by parish councils or parish meetings. There are also some matters of local administration arising under what are called commissions of sewers. These exist for the purpose of regulating drainage, and providing defence against water in fen lands or lands subject to floods from rivers or tidal waters. The commissioners derive their authority from the Sewers Commission Acts, which date from the time of Henry VIII., from the Land Drainage Act, 1861, and from various local Acts. It is unnecessary, however, to consider in any detail the powers exercised by commissioners of sewers in the few areas under their control.

Loch, Henry Brougham Loch, 1st BARON (1827–1900), British administrator, son of Mr James Loch, M.P., of Drylaw, Midlothian, was born on 23rd May 1827. At first destined for a naval career, he soon quitted the navy for the East India Company's military service, and in 1842 obtained a commission in the Bengal Light Cavalry. On the outbreak of the Sikh war in 1845 he was given an appointment on the staff of Sir Hugh Gough, and served throughout the Sutlej campaign, where he displayed the cool courage and unshakeable resolution which continued to characterize his subsequent career. In 1852 he became second in command of that famous corps, Skinner's Horse. At the outbreak of the Crimean war in 1854,

Loch, eager for service at the front, severed his connexion with India, and obtained leave to raise a body of irregular Bulgarian cavalry, which he commanded throughout the war. In 1857 he was appointed attaché to Lord Elgin's mission to the East, was present at Tientsin, and brought home the Treaty of Yedo in the following year. He now abandoned his military career, and in 1859 went out again as secretary to Lord Elgin's second mission to China. Here he was involved in an adventure which came near costing him his life. He had advanced with a small guard to a place called Tungchow, to arrange the preliminaries for the negotiations, when he found that the Chinese had treacherously gathered a great army to surprise the British forces. He rode back to warn Sir Hope Grant, and then returned through the enemy's lines to rejoin his companions, Bowlby and Parkes. Before they could effect their retreat, the battle had begun; they were seized by the beaten Chinese, and hurried off to Peking, where they were put into cages and subjected to other indignities. Loch was rescued in the nick of time. Returning home, he was made C.B., and for a while occupied the less adventurous post of private secretary to Sir George Grey, who was then at the Home Office. In 1863 he was appointed Lieutenant-Governor of the Isle of Man. His long and successful tenure of this post coincided with a period of active progress in the island. It was during this time that the House of Keys was transformed into an elective assembly, the first line of railway was opened, and the influx of tourists began to bring fresh prosperity. In 1882 Sir H. Loch, who had become K.C.B. in 1880, accepted a Commissionership of Woods and Forests, and two years later was made Governor of Victoria, where he won the esteem of all classes. In 1889 he succeeded Sir Hercules Robinson as Governor of Cape Colony and High Commissioner of South Africa. His term of office coincided with a period of unrest that called for a firm hand. Immediately after his arrival he held a conference with President Kruger, and concluded the Swaziland Convention of 1890, which offered the Transvaal an outlet to the sea at Kosi Bay on condition of its joining the South African Customs Union. The Banyailand "trek" of 1891 was nipped in the bud by his prompt action. When the commandeering difficulty of 1894 had roused the Uitlanders in the Transvaal to a dangerous pitch of excitement, he travelled to Pretoria to use his personal influence with President Kruger. He was received with a memorable outburst of enthusiasm, and, with characteristic prudence, cancelled his projected visit to Johannesburg, for fear his presence might be the signal for excesses that could only injure the Uitlanders. Sir H. Loch, by the firm attitude he took up, obtained the withdrawal of the obnoxious commandeering regulations; but a memorandum, pressing for redress of the Uitlanders' whole position, was cancelled at the last moment by order of the Colonial Secretary, Lord Ripon. In the following year he entered a strong protest against the new franchise law; and finding that President Kruger had not fulfilled the conditions of the Swaziland Convention, he declared it abrogated, and annexed the Zambaan and Umbegesa territories to the British Crown. This was the last important act of his administration. He had, by his openness of mind and his personal charm of manner, won the goodwill of British and Dutch alike, including President Kruger himself. At critical moments he had behaved with coolness and resolution, and, both at the time of the Banyailand "trek" and during the Johannesburg agitation, had not hesitated to make such military dispositions as he believed necessary for the safeguarding of Imperial interests. But, whether from his own fault, or from dissensions on Imperial questions in the Home Government, he had contented himself with a settlement of each separate difficulty as it arose,

while the general situation assumed year by year a more threatening aspect. Mr Rhodes, then Prime Minister of Cape Colony, was strongly in favour of a more energetic policy, and in 1895 the High Commissioner, finding himself out of touch with his ministers, resigned his office and returned home. In the same year he was raised to the peerage. He died in London on 20th June 1900. (H. S.)

Loches, chief town of arrondissement, department of Indre-et-Loire, France, on the river Indre, 25 miles south-east of Tours by rail. The castle of Loches was in the Middle Ages a fortress of the first class. The outer enclosure, nearly two miles in circumference, surrounds (1) a collegiate church (now the parish church), founded in the 10th century, and in some respects unique in French architecture; (2) a royal lodge (now the sub-prefecture), built by Charles VII. over subterranean chambers, rediscovered in 1869; and (3) the fortress proper, which eventually came to be used as a state prison, the terrors of which almost equalled those of the Bastille. Population (1901), 5161.

Lochgelly, a police burgh and railway station of Fifeshire, Scotland, $7\frac{1}{2}$ miles north-east of Dunfermline. The town, which takes its name from a small lake, half a mile to the south-east, is of modern origin, and owes its prosperity to its iron-works and the large collieries in the immediate vicinity. The majority of the houses are small, but the town is regularly built, and the water and sewerage arrangements are satisfactory. There are some good shops, and the public buildings include a music hall, a co-operative hall, and a commodious and handsome drill hall. To the north-west of the lake is Lochgelly House, a seat of the Earl of Minto. Population (1881), 2601; (1900), 5472.

Lockerbie, a police burgh and market town of Annandale, Dumfriesshire, Scotland, $14\frac{1}{2}$ miles east-north-east of Dumfries by rail. It is an important centre for the dispersal of lambs—126,000 were sold in the autumn of 1899. There is an ancient square tower—once a family seat, and afterwards for many years a gaol,—a town hall, and a mechanics' hall. Population (1881), 2029; (1901), 2358.

Locker - Lampson, Frederick (1821-1895), better known as **FREDERICK LOCKER**, English man of letters, was born, on the 29th of May 1821, at Greenwich Hospital. His father, who was Civil Commissioner of the Hospital, was Edward Hawke Locker, youngest son of that Captain William Locker who gave Nelson the memorable advice, "to lay a Frenchman close, and beat him." His mother, Eleanor Mary Elizabeth Boucher, was a daughter of the Rev. Jonathan Boucher, vicar of Epsom and friend of George Washington. After a desultory education, Frederick Locker began life in a colonial broker's office. Soon deserting this uncongenial calling, he obtained a clerkship in Somerset House, whence he was transferred to Lord Haddington's private office at the Admiralty. Here he ultimately became deputy-reader and *précis* writer. In 1850 he married Lady Charlotte Bruce, daughter of the Lord Elgin who brought the famous marbles to England, and sister of Lady Augusta Stanley. After his marriage he left the Civil Service, in consequence of ill-health. In 1857 he published *London Lyrics*, a slender volume of 90 pages, which, with subsequent extensions, constitutes his poetical legacy. *Lyra Elegantiarum* (1867), an anthology of light and familiar verse, and *Patchwork* (1879), a book of extracts, were his only other publications. In 1872 Lady Charlotte Locker died. Two years later Locker married Miss Hannah Jane Lampson, the only daughter of Sir Curtis Miranda Lampson, Bart., of Rowfant, Sussex, and in 1885 took

his wife's surname. At Rowfant he died, 30th May 1895. Chronic ill-health debarred Locker from any active part in life, but it did not prevent his delighting a wide circle of friends by his gifts as a host and *raconteur*, and from accumulating many treasures as a connoisseur. His books are catalogued in the volume called the *Rowfant Library*, 1886, to which an appendix (1900) was added, after his death, under the superintendence of his eldest son. As a poet, Locker belongs to the choir who deal with the gay rather than the grave in verse—with the polished and witty rather than the lofty or emotional. His good taste kept him as far from the broadly comic on the one side as his kind heart saved him from the purely cynical on the other. To something of Prior, of Præd, and of Hood he added qualities of his own which lent his work distinction—a distinction in no wise diminished by his unwearied endeavour after directness and simplicity. A posthumous volume of Memoirs, entitled *My Confidences* (1896), and edited by his son-in-law, Mr Augustine Birrell, gives an interesting idea of his personality and a too modest estimate of his gifts as a poet. (A. D.)

Lockhart, Sir William Stephen Alexander (1841–1900), British general, was born in Scotland, 2nd September 1841, his father being a Lanarkshire clergyman. He entered the Indian army in 1858, in the Bengal native infantry, and rose to be captain (1868), lieutenant-colonel (1879), major-general (1891), lieutenant-general (1894), and general (1896). He served in the Indian Mutiny, the Bhutan campaign (1864–66), the Abyssinian expedition (1867–68; mentioned in despatches), the Hazara Black Mountain expedition (1868–69; mentioned in despatches). From 1869 to 1879 he acted as deputy-assistant and assistant quartermaster-general in Bengal. In 1877 he was military attaché with the Dutch army in Acheen. He served in the Afghan war of 1878–80, was mentioned in despatches and made a C.B., and from 1880 to 1885 was D.Q.G. in the intelligence branch at headquarters. He commanded a brigade in the Burmese war (1886–87), and was made K.C.B., C.S.I., and received the thanks of the Government. An attack of fever brought him to England, and he was employed as assistant military secretary for Indian affairs; but in 1890 he returned to India to take command of the Punjab frontier force, and for five years was engaged in various expeditions against the hill tribes. After the Waziristan campaign in 1894–95 he was made K.C.S.I. In 1897 he was given the command against the Afridis and Mohmands, and conducted the difficult Tirah campaign (*q.v.*) with great skill. He was made G.C.B., and in 1898 became commander-in-chief in India. His career was cut short, however, by his death on 18th March 1900. Sir William Lockhart was not only a first-rate soldier, but also had a great gift for dealing with the native tribesmen. Among the latter he had the *sobriquet* of Amir Sahib, on account of their respect and affection for him.

Lock Haven, a city of Pennsylvania, U.S.A., capital of Clinton county, on the west branch of the Susquehanna river, on the Pennsylvania canal and the Pennsylvania and the Beechcreek (part of the New York Central system) railways, at an altitude of 579 feet. It is in a lumber region, has several saw-mills, and ships annually large quantities of lumber. Population (1880), 5845; (1890), 7358; (1900), 7210, of whom 618 were foreign-born and 122 negroes.

Lockport, a village of Will county, Illinois, U.S.A., on the Des Plaines river, five miles above Joliet, on the Chicago and Alton, and the Atchison, Topeka, and Santa Fé railways, at an altitude of 570 feet. Population (1880), 1679; (1890), 2449; (1900), 2659.

Lockport, a city of New York, U.S.A., capital of Niagara county, on the Erie canal, and on the Erie and the New York Central and Hudson River railways, at an altitude of 594 feet. The locks in the Erie canal, from which the city derives its name, are ten in number, five for ascending and five for descending the 60-foot rise in the canal at this point. The surplus water from Tonawanda creek, after supplying the canal, furnishes an excellent water-power, which has been put to use in a variety of manufactures. Among them are plants for the Holly heating system, by which steam is supplied through street mains to homes and other buildings from a central generator. Population (1890), 16,038; (1900), 16,581, of whom 2936 were foreign-born and 160 were negroes.

Lockroy, Edouard [ETIENNE-AUGUSTE-EDOUARD SIMON] (1838—), French politician, son of Joseph Philippe Simon (1803–1891) dramatist and actor (who took the name of Lockroy), was born in Paris, 18th July 1838. He began by studying as an artist, but in 1860 took part in Garibaldi's expedition to Sicily, and, after acting as secretary to Renan on his tour in Palestine (1864), took to journalism in Paris as a fierce opponent of the Empire. He commanded a battalion during the siege of Paris in 1870, and in 1872 was elected deputy for the Seine. During the stormy period that followed he was several times imprisoned for his violent articles in the press, but his name became known to the public, and he was elected deputy for Bouches-du-Rhone in 1873, and in 1876 for Aix. He continued afterwards to be returned to the Chamber, and took a prominent part in affairs as one of the Extreme Left. In 1877 he had married the widow of Victor Hugo's son. He was minister of commerce in the cabinets of M. Freycinet and M. Goblet (1886–87), minister of education under M. Floquet (1888–89), and minister of marine under M. Bourgeois (1895–96), under M. Brisson (1898), and M. Dupuy (1898–99). He devoted both his pen and his policy to the reorganization of the French navy on modern lines, and became the best-known advocate of naval reform in France; and the activity shown in French naval matters towards the end of the century was largely owing to his persistence.

Lockwood, Sir Frank (1846–1897), English lawyer, was born at Doncaster in 1846. His grandfather and great-grandfather were mayors of Doncaster, and the former for some years filled the office of judge on the race-course. He was educated at a private school, at Manchester Grammar School, and Caius College, Cambridge. Called to the bar at Lincoln's Inn in 1872, he joined the old Midland circuit, afterwards going to the north-eastern, and did well enough to make in his first year 120 guineas, and in the next 265 guineas. From that time he had a career of uninterrupted success. In 1882 he was made a Queen's Counsel, in 1884 he was made Recorder of Sheffield, and in 1894 he became Solicitor-General in Lord Rosebery's ministry, and was knighted, having first entered Parliament as member for York in 1885, after two unsuccessful attempts, the one at King's Lynn in 1880, the other at York in 1883. He was Solicitor-General for less than a year. In 1896 Lord Chief Justice Coleridge, Mr Montague Crackanthorpe, and Sir Frank Lockwood went to the United States to attend, as specially invited guests, the nineteenth meeting of the American Bar Association, and to represent the power, learning, and humour of the English bar thereat. On this trip Sir Frank Lockwood sustained the reputation which he enjoyed in England as a humorous after-dinner speaker, and helped to strengthen the bond of friendship which unites the bench and bar of the United States with the bench and bar of England. He died in London on 18th December 1897.

A brief epitome of Sir Frank Lockwood's legal achievements can give no idea of his unique personality, and of the manner in which it contributed to his success. He was a big, cheery, rubicund Yorkshireman, with a jovial manner, a sonorous voice, a ready tongue, and a sense of humour that never deserted him. No one can doubt that Frank Lockwood owed his success in a grave profession as much to this sense of humour and to his power to excite merriment as to any of his other qualities. His first brief was in the Rolls Court, a solemn tribunal now no more. "What brings *you* here?" asked Lord Romilly, as he rose to address the court. "Three and one, my Lord," replied young Lockwood, after an eloquent glance at the fee marked in guineas on his brief. The precise effect of the answer on the Master of the Rolls is not recorded, but the story clung to Lockwood as long as he remained at the bar, among hundreds of others, some possibly apocryphal, all enhancing his reputation for quick retort and imperturbable coolness. He had, moreover, considerable talent for drawing, inherited from his father, which he employed chiefly for the amusement of himself and his friends, in the making of admirable caricatures in pen and ink, and of sketches of humorous incidents, real or imaginary, relating to the topic nearest at hand, many of which, being made in court, found their way into the possession of his friends and others near him, sometimes of the judge who tried the case. An exhibition of them was held soon after his death. Many have been reproduced, some in Mr Augustine Birrell's excellent little biography, and more in *The Frank Lockwood Sketch-Book* (1898). Sir Frank Lockwood neither was nor pretended to be a profound lawyer, but he was an advocate who would influence juries, an incisive and ready cross-examiner, an eloquent and, as a rule, tactful speaker, with great power of bringing his adversary's case or witness into ridicule and contempt, where such a course seemed likely to prove effective. In these circumstances, although he was engaged in many heavy cases, such as the Parnell Commission, he won his reputation at the bar mainly in the class of trial popularly defined as *causes célèbres*, in the Divorce Court, in trials connected with the turf, in the exposure of fraud, in the prosecution, and still more in the defence, of prisoners. In private life he had a vast number of friends and no enemies. With inherited tastes for sport, he was fond of riding, of shooting, and of the race-course; in early life he was very fond of acting, and, although he perhaps never seriously contemplated adopting the theatrical profession, he went on tour with his friends, Mr and Mrs Kendal, and always took considerable interest in the stage. He was a great admirer of Dickens, and a lecture on "The Law and Lawyers of *Pickwick*," delivered by him at York, and afterwards at the Morley Hall, Hackney, to some of the constituents of his friend, Sir Charles Russell (afterwards Lord Chief Justice), was published by the Roxburgh Press, with a sketch of Sergeant Buzfuz by the author as a frontispiece. Sir Frank Lockwood married, in 1874, Julia, second daughter of Mr Salis Schwabe, by whom he had a family.

(E. A. AR.)

Lockyer, Sir Joseph Norman (1836—), English astronomer, was born at Rugby on the 17th May 1836. After completing his education on the Continent, he obtained a clerkship in the War Office in 1857. His leisure was devoted to the study of astronomy, and the proofs of scientific skill and of business capacity which he gave led to his appointment as secretary of the duke of Devonshire's commission on science in 1870. In 1875 he was transferred to the Science and Art Department at South Kensington, and on the foundation of the Royal College of Science he

became Director of the Solar Physical Observatory and Professor of Astronomical Physics. He was leader of the British Government expeditions for observation of the solar eclipses occurring from 1870 to 1897. In 1874 he received the Rumford medal of the Royal Society, of which he became a Fellow in 1869, for his spectroscopic researches on the sun and on the chemical elements. In 1868 he was able to communicate to the Royal Society and the Paris Academy a report of his successful observations of the solar prominences in broad daylight by the aid of the spectroscope. It happened that Dr Janssen, who had observed the spectra of the prominences during the total eclipse of August 1868, had applied his instrument to them on the following day, and his report reached the Paris Academy of Sciences a few days after that body had received Lockyer's communication. But, as Sir Joseph Hooker, the President of the Royal Society, said, when handing Lockyer the Rumford medal, "nothing interferes with the perfect independence with which the two physicists established the possibility of detecting the prominences at any time." The names of both astronomers appear on a medal which was struck by the French Government in 1872 to commemorate the discovery. In addition to numerous contributions to the *Proceedings* of the Royal and the Royal Astronomical societies, Sir Norman Lockyer is the author of several popular books on astronomy, and also of some ambitious treatises in which he passes from the explanatory to the theoretical. Eminent as a spectroscopist, although in this department some of his conclusions are not established, he has, in the *Dawn of Astronomy*, *The Meteoritic Hypothesis*, *The Sun's Place in Nature*, and other works, propounded various theories which have failed to commend themselves to the majority of astronomers; dissent has been especially expressed by competent spectroscopists and physicists from his theory of the origin of cosmical systems, namely, that all the varied orders of bodies which the heavens present to view are alike composed of meteorites, "the chief difference between the several orders being due either to the degree of aggregation of meteorites in the swarm, or, in the case of consolidated swarms, to the time which has elapsed since their complete evaporation." His later investigations into an assumed relation between sun-spots and rainfall on the globe remain in the speculative stage. He was created K.C.B. in 1897.

Locle, Le, a town in the Swiss canton of Neuchâtel, 23 $\frac{3}{4}$ miles by rail north-west of Neuchâtel. The watch-making industry dates from 1680. The subterranean mills of the Col des Roches (the railway now traverses this gorge by means of four tunnels) in the neighbourhood, as also the Lac des Brenets, and waterfall of the Doubs on the French frontier, are worth a visit. The population has risen from 10,215 in 1870 to 10,387 in 1880 and 12,624 in 1900, mainly Protestants and French-speaking. The church (built in 1521) is the only old building in the town.

Łódź (Łódź, and more correctly *Łódzia*), a manufacturing town of Russian Poland, government Piotrków, 87 miles by rail south-west of Warsaw. It is situated on the Łódź plateau, which at the beginning of the 19th century was covered with impenetrable forests. Now it is the centre of quite a group of industrial towns—Zgierz, Łęczyca, Pabianice, &c., and is connected by a branch railway with the main line from Warsaw to Vienna, and five macadamized main roads radiate from it. Chiefly owing to a considerable immigration of German capitalists and workers, Łódź has grown with American-like rapidity. It consists chiefly of one main street, 6 miles long, and is a sort of Polish Manchester, manufacturing cottons, woollens,

and mixed stuffs. One of the very few educational institutions is a professional school. The population, which was only 50,000 in 1872, reached 315,209 in 1897, the Poles numbering about 40 per cent., Germans 33 per cent., and Jews 27 per cent.

Lofoten and **VESTERAALEN**, two groups of islands on the west coast of Norway. The permanent population is 35,000 to 40,000, and about the same number are added in the fishing season (January-April). There are factories for fish guano at the fishing-stations of Henningvær, Kabelvaag, and Svolvær on Öst-Vaag Island, at Lödingen on Hind Island, and at Brettesnäs on South Molla. The total trade is valued at £20,000 to £70,000 annually. The violent tempests which sweep over the Vest Fjord are graphically described in Jonas Lie's *Den Fremsynte* (1870) and in H. Schultze's *Udvalgte Skrifter* (1883), as the Maelström, which is near the southern end of the group, is imaginatively by Edgar Allan Poe.

Log.—On leaving the land and before the position of a ship can be ascertained by astronomical observations, the intermediate positions are required for the safe navigation of the ship. For this purpose speed indicators were introduced, known as the common and patent logs; the number of revolutions made by the engines may also, in favourable circumstances, be utilized for this purpose.

Common Log.—With high speeds the reel held by men has been superseded by a fixed reel with winch for heaving in the log line, and fitted with a brake to check the line when running out. In a steamer running at high speed on an ocean route, engines working smoothly and uniformly, a careful officer, with correct log line and glass, will attain most accurate results from the common log (see *Log, Ency. Brit.* vol. xiv. p. 769).

Patent Log.—Under this heading may be placed the pressure and electric logs now discarded, and the present screw or fan log, known generally as the patent log. The crude germ of the latter invention, with the substitution of wheels in a closed box for a rotating screw, is probably due to Humphry Cole about 1570. Foxon of Deptford in 1772, Guerimand of Middlesex in 1776, and Gower in 1792 by mechanical means practically demonstrated the regis-

FIG. 1.—The A1 Harpoon Ship Log.

tration of a vessel's speed; the method in 1807 of Viscount de Vaux was with water pressure. In 1802 Edward Massey produced a patent log (*Log*, 9th edition), which came into general use in 1836 and continued until 1861; in the latter year Walker's harpoon or frictionless log was introduced. The wheelwork was enclosed in a cylindrical case of the same diameter as the body of the rotator or fan, and the latter brought close up to the register, thus forming a compact machine and avoiding the previous use of the 6-foot line. Two years later a heart-shaped float plate was attached to the case, and the log was called the A1 Harpoon ship log (Fig. 1), the one usually employed for towing. The log should be washed in fresh water when practicable, to prevent oxidization of

the wheels, and be lubricated with suitable oil through a hole in the case. Alexander Bain in 1846 suggested enclosing the wheelwork in the rotator. With quick passages and well-surveyed coasts, the problems in

FIG. 2.—The Cherub Log.

coastal navigation required a patent log that could be readily consulted from the deck, and one from which the distance run in thick weather under varying speeds could be quickly ascertained. To meet this requirement in 1878 Walker introduced the Cherub log (Fig. 2), a taffrail one, which, however, is not as a rule used for speeds over 18 knots. Owing to the increased friction produced by a rotator making approximately 900 revolutions per mile, towed at the end of a line varying from 40 fathoms for a 12-knot speed to 60 fathoms for 20 knots, the pull of the line and rotator is borne by cone rollers, having their outlines tapering to a common point in their rotation, thus giving a broad rolling surface. Strong worms and wheels are also substituted for the light clockwork. In Fig. 2 the shoe H is secured to the taffrail, the rotator in the water is hooked to the eye of the spindle M by the hook D. The case A contains the registering wheelwork and a sounding bell. The half gimbal B pivoting in the socket of the base C allows the register to receive the strain in the direct line. The bearings and rollers are lubricated with castor-oil every twelve hours through holes in the sliding case E, and can be examined by unscrewing the case E and the eye M. When not in use, the register is removed from the shoe by lifting a small screw button near C. The tow-line is usually plaited, and to

avoid a knot close to the rotator, the latter is secured to the former by a knot inside an egg-shaped shell (Fig. 3, Neptune pattern). Walker's Neptune log (Fig. 4)

is used for vessels of high speed. Case A contains the wheelwork, E the spindle and steel bearings; in each case are openings, closed by sliding tubes, for examination and lubrication. In Fig. 4 the cases A and E are shown open. Fig. 5 shows the dial-plate. In Fig. 6 the ball bearings are shown unscrewed from the body of the

Fig. 5.—Dial-plate of Neptune Log.

locked by a special washer and the two screws *a*, *a* (Figs. 6, 7). If the outer races become worn, the complete cage and bearings are reversed; the strain of the line is then transferred to what had previously been the inner with practically unworn balls and races. It is for this purpose that the skeleton cage is screwed internally at both ends, fitting a screwed ring inside the cap F (Fig. 4). Walker's Rocket log (Fig. 8) is a taffrail one, with bearings of hardened steel, and is intended to be slung or secured to the taffrail by a line; the gimbal pattern has a fitting for the deck. In taffrail logs the movement of the line owing to its length becomes spasmodic and jerky, increasing the vibration and friction; to obviate this a governor or fly-wheel is introduced, the hook of the tow-line K (Fig. 9) and the eye of the register M being secured to the governor. Fig. 9 represents the arrangement fitted to the Neptune log; with the Cherub log a

Fig. 6.—Ball Bearings of Neptune Log.

Fig. 7.—Ball Bearings of Neptune Log in Skeleton Case.

small piece of line is introduced between the governor and the eye of the register. The two principal American taffrail logs are the Negus and Bliss (Messrs Norie and Wilson). The former bears a general resemblance to the Cherub log, but the dial-plate is horizontal and the faces turn upwards. The main shaft bearings are in two sets and composed of steel balls running in steel cones and cups; the governor is an iron rod about 16

inches long, with 1-inch circular balls at the extremities. The Bliss resembles the Rocket log in shape, and is secured to the taffrail by a rope, or slung. A governor is not employed. The blades of the rotator are adjustable, being fitted into its tube or body by slits and holes

Fig. 8.—Rocket Log.

and then soldered. The outer ends of the blades are slit (Fig. 10) to form two tongues, and with the wrench (Fig. 10) the angle of the pitch is altered. All patent logs have errors, which should be ascertained by shore observations when passing a well-surveyed coast in tideless waters on a calm day. Constant use, increased friction (more especially at high speeds), and damage to the rotator will alter an ascertained log error; head or following seas, strong winds, currents, and tidal streams affect the correctness of a patent log.

Fig. 9.—Neptune Log fitted with Governor.

Log Book is a marine or sea journal, containing, in the Royal Navy, the speed, course, leeway, direction and force of the wind, state of the weather, and barometric and thermometric observations. Under the heading "Remarks" are noted (for vessels with sail power) making, shortening, and trimming sails; and (for all ships) employment of crew, times of passing prominent landmarks, altering of course, and any subject of interest or importance. The deck log-book, kept by the officers of the watch in pencil, is copied in ink into the ship's log-book by the navigating officer, and the latter is an official journal.

Fig. 10.—Bliss Log.

In steam vessels a rough and fair engine-room register are kept, giving information with regard to the engines and boilers. In the British mercantile marine all ships (except those employed exclusively in trading between ports on the coasts of Scotland) are compelled to keep an official log-book in a form approved by the Board of Trade. A mate's log and engine-room register are not compulsory, but are usually kept. (J. W. D.)

Logan, John Alexander (1826–1886), American soldier and politician, was born in Jackson county, Illinois, on the 9th of February 1826. As a boy he was disinclined for schooling, and in the Mexican war he became lieutenant in an Illinois regiment. Later he studied and practised law, but soon drifted into politics as a Democrat, and served several terms in the State Legislature. In 1858 and 1860 he was elected to Congress, but at the outbreak of the Civil War he resigned his seat and

entered the Union army as colonel of volunteers. As a fighting officer his career was distinguished. In Grant's campaigns, terminating at Vicksburg, he rose to the rank of major-general, and under Sherman he commanded an army corps, and eventually the army of the Tennessee. When the war closed Logan resumed his political career, but as a member of the Republican party, and served in Congress, with but slight intermission (1877-78-79), from 1866 till his death at Washington on the 26th of December 1886. He was always a violent partisan. In 1868 he was one of the managers in the impeachment of President Johnson, and in the Senate he was identified with the Radical wing of his party. This latter fact contributed to his nomination for Vice-President in 1884. His impetuous oratory, though popular on the platform, was less adapted to the halls of legislation.

Logan, a city of Utah, U.S.A., capital of Cache county, in Cache Valley, at the west base of Bear River Range, at an altitude of 4506 feet. It is regularly laid out on a level site, and is on a branch of the Oregon Short Line railway. Its inhabitants are almost entirely Latter Day Saints. The surrounding region is highly cultivated, being supplied with water for irrigation from the numerous streams coming out of the mountains. Population (1880), 3396; (1890), 4565; (1900), 5451, of whom 1440 were foreign-born.

Logansport, a city of Indiana, U.S.A., capital of Cass county, at the junction of the Wabash and the Eel rivers, at an altitude of 724 feet. It is on the Wabash and Erie canal, and on the Pittsburg, Cincinnati, Chicago and St Louis, the Vandalia, and the Wabash railways. It has extensive manufactures of varied description. Population (1890), 13,328; (1900), 16,204, of whom 1432 were foreign-born.

Logia (Λόγια Ἰησοῦ: "Sayings of our Lord").—Several early Christian writers speak of *λόγια τοῦ κυρίου*, or τὰ κυριακὰ λόγια, i.e., oracles of (or concerning) the Lord. For example, Polycarp speaks of those "who pervert the oracles of the Lord" (*Philipp.* 7), and Papias, according to Eusebius (*Hist. Eccl.* iii. 39), wrote a work with the title, "Expositions of the Oracles of (or concerning) the Lord." The expression has been variously interpreted. It need mean no more, as Lightfoot has shown (*Essays on Supernatural Religion*, 172 f.), than "narratives of (or concerning) the Lord"; this would be fully in accordance with the existing Jewish usage, and it is probable that Papias uses it in this sense. It is capable, however, of a more definite meaning. Resch has endeavoured to prove that there was a primitive gospel, written in Hebrew, containing a narration of the miracles and discourses of the Lord, and known as *λόγια Ἰησοῦ* (לשׁוֹן יֵשׁוּעַ), or the like (*Agrapha*); whilst others have surmised that the Logia consisted of a collection of sayings of our Lord, which formed the nucleus of the four canonical Gospels. In these circumstances, great interest was roused by the publication in 1897, by Messrs B. P. Grenfell and A. S. Hunt, of some eight "Sayings of the Lord" (or possibly seven: Dr Swete thinks that the fourth *λόγιον* is really part of the third). They were found amongst the great mass of papyri acquired by the Egyptian Exploration Fund from the ruins of Oxyrhynchus, one of the chief early Christian centres in Egypt, situated some 120 miles south of Cairo. This fragment, which the editors believe to have been written "not much later than A.D. 200," certainly before 300, is numbered 11, so that it was preceded by ten other leaves, which may probably have contained "Sayings" of the same kind. No others, however, have as yet been discovered. The Logia have been much

discussed, without, however, any very determinate result being reached. It is generally agreed that they do not take us behind the existing canonical Gospels, but that they are themselves based on them and on later writings, known and unknown. Harnack maintains that they are excerpts from the lost *Gospel of the Egyptians*. Anyhow, their chief interest on external grounds lies in the evidence that they supply that such collections were really made.

The eight "Sayings" have, however, no little intrinsic interest. They are given as follows, in their revised form, by the discoverers:—

1. . . . καὶ τότε διαβλέψεις ἐκβαλεῖν τὸ κάρφος τὸ ἐν τῷ ὀφθαλμῷ τοῦ ἀδελφοῦ σου.
2. Λέγει Ἰησοῦς ἐὰν μὴ νηστεύσητε τὸν κόσμον οὐ μὴ εὔρετε τὴν βασιλείαν τοῦ θεοῦ· καὶ ἐὰν μὴ σαββατίσητε τὸ σάββατον οὐκ ὄψασθε τὸν πατέρα.
3. Λέγει Ἰησοῦς ἔ[σ]την ἐν μεσῷ τοῦ κόσμου καὶ ἐν σαρκὶ ὠφθην αὐτοῖς, καὶ εὔρον πάντας μεθύνοντας καὶ οὐδένα εὔρον διψῶντα ἐν αὐτοῖς, καὶ ποιεῖ ἡ ψυχὴ μου ἐπὶ τοῖς υἱοῖς τῶν ἀνθρώπων, ὅτι τυφλοὶ εἰσιν τῇ καρδίᾳ αὐτῶ[ν] κ[αὶ] οὐ βλέ[ουσιν]. . . .
4. [Illegible: possibly joins on to 3] . . . [τ]ῆν πτωχείαν.
5. [Λέγ]ει Ἰησοῦς ὅπ[ου] ἐὰν ὦσιν [β, οὐκ] ε[λίσ]ιν ἄθεοι· καὶ [δ]που ε[λίσ]ιν ἔστιν μῆσος, [λέ]γω, ἐγὼ εἰμι μετ' αὐτ[οῦ]· ἔγει[ρον] τὸν λίθον καὶ ἐνρησείς με, σχίσον τὸ ξύλον καὶ ἐκεῖ εἰμι.
6. Λέγει Ἰησοῦς οὐκ ἔστιν δεκτὸς προφήτης ἐν τῇ πατρίδι αὐτ[οῦ], οὐδὲ ἰατρὸς ποιεῖ θεραπείας εἰς τοὺς γινώσκοντας αὐτόν.
7. Λέγει Ἰησοῦς οἰκοδομημένη ἐπ' ἄκρον βρους ὑψηλοῦ καὶ ἐστηρικμένη οὐτε πε[ρ]σ[εῖν] δύναται οὐτε κρυ[β]ήναι.
8. Λέγει Ἰησοῦς ἀκούεις [ε]ἰς τὸ ἐν ᾧ τῶν σου τὸ [δὲ ἔτερον συνέκλεισας].

Letters in brackets are missing in the original: letters which are dotted beneath are doubtful. No. 5 is Dr Blass's reconstruction, No. 8 that of Dr Swete.

1. ". . . and then shalt thou see clearly to cast out the mote that is in thy brother's eye."
2. "Jesus saith, Except ye fast to the world, ye shall in no wise find the kingdom of God; and except ye make the sabbath a real sabbath, ye shall not see the Father."
3. "Jesus saith, I stood in the midst of the world and in the flesh was I seen of them, and I found all men drunken, and none found I athirst among them, and my soul grieveth over the sons of men, because they are blind in their heart, and see not. . . ."
4. ". . . poverty . . ."
5. "Jesus saith, Wherever there are two, they are not without God, and wherever there is one alone, I say, I am with him. Raise the stone and there thou shalt find me, cleave the wood and there am I."
6. "Jesus saith, A prophet is not acceptable in his own country, neither doth a physician work cures upon them that know him."
7. "Jesus saith, A city built upon the top of a high hill and established can neither fall nor be hid."
8. "Jesus saith, Thou hearest with one ear [but the other ear hast thou closed]."

The greater number of these are clearly based upon, or parallel with, passages in the Gospels; but the second, third, and the latter part of the fifth have a special interest, because of their novelty. The second can only be our Lord's if it is to be understood metaphorically. Dr J. B. Mayor has adduced parallels from Clement of Alexandria which are so to be understood, but it may be doubted whether this does not rather come from some Ebionitic sect which unduly exalted fasting and the sabbath. The third may be taken from some unknown apocryphal work, and its language appears to be based upon Baruch iii. 38. The fifth is perhaps the most interesting of all. Various interpretations have been suggested: that the Lord is in all things, since in Him they are made; that the emphasis is to be laid on the difficulty of the acts, and their danger; or that the Stone and the Wood are types of Him. Some modification of the second view is strongly suggested by Eccl. x. 9: "Whoso removeth stones shall be hurt therewith, and he that cleaveth wood shall be endangered thereby"; on the other hand, the first is by no means impossible.

L O G I C.

§ 1. GENERAL TENDENCIES OF RECENT LOGIC.

THERE are several grounds for hope in the logic of our day. In the first place, it tends to take up an intermediate position between the extremes of Kant and Hegel. It does not, with the former, regard logic as purely formal in the sense of abstracting thought from being, nor does it follow the latter in amalgamating metaphysics with logic by identifying being with thought. Secondly, it does not content itself with the mere formulæ of thinking, but pushes forward to theories of method, knowledge, and science; and it is a hopeful sign to find this epistemological spirit, to which England was accustomed by Mill, animating German logicians such as Lotze, Dühring, Schuppe, Sigwart, and Wundt. Thirdly, there is a determination to reveal the psychological basis of logical processes; not merely to describe them as they are in adult reasoning, but to explain also how they arise from simpler mental operations and primarily from sense. This attempt is connected with the psychological turn given to recent philosophy by Wundt and others, and is dangerous only so far as psychology itself is hypothetical. Unfortunately, however, these merits are usually connected with a less admirable characteristic — contempt for tradition. Writing his preface to his second edition in 1888, Sigwart says: — “Important works have appeared by Lotze, Schuppe, Wundt, and Bradley, to name only the most eminent; and all start from the conception which has guided this attempt. That is, logic is grounded by them, not upon an effete tradition, but upon a new investigation of thought as it actually is in its psychological foundations, in its significance for knowledge, and its actual operation in scientific methods.” How strange! The spirit of every one of the three reforms above enumerated is an unconscious return to Aristotle’s *Organon*. Aristotle’s was a logic which steered, as Trendelenburg has shown, between formalism and metaphysics; it was a logic which in the *Analytics* investigated the syllogism as a means to understanding knowledge and science; it was a logic which, starting from the psychological foundations of sense, memory, and experience, built up the logical structure of induction and deduction on the profoundly Aristotelian principle that “there is no process from universals without induction, and none by induction without sense.” Wundt’s comprehensive view that logic looks backward to psychology and forward to epistemology was hundreds of years ago one of the many discoveries of Aristotle.

§ 2. JUDGMENT.

(1) *Judgment and Conception*.—The emphasis now laid on judgment, the recovery from Hume’s confusion of beliefs with ideas and the association of ideas, and the distinction of the mental act of judging from its verbal expression in a proposition, are all healthy signs in recent logic. The most fundamental question, before proceeding to the investigation of inference, is not what we say but what we think in making the judgments which, whether we express them in propositions or not, are both the premisses and the conclusion of inference; and, as this question has been diligently studied of late, but has been variously answered, it will be well to give a list of the more important theories of judgment as follows: —

(a) It expresses a relation between the content of two ideas, not a relation of these ideas (Lotze).

(b) It is consciousness concerning the objective validity

of a subjective combination of ideas, *i.e.*, whether between the corresponding objective elements an analogous combination exists (Ueberweg).

(c) It is the synthesis of ideas into unity and consciousness of their objective validity, not in the sense of agreement with external reality but in the sense of the logical necessity of their synthesis (Sigwart).

(d) It is the analysis of an aggregate idea (*Gesamtvorstellung*) into subject and predicate; based on a previous association of ideas, on relating and comparing, and on the apperceptive synthesis of an aggregate idea in consequence; but itself consisting in an apperceptive analysis of that aggregate idea; and requiring will in the form of apperception or attention (Wundt).

(e) It requires an idea, because every object is conceived as well as recognized or denied; but it is itself an assertion of actual fact, every perception counts for a judgment, and every categorical is changed into an existential judgment without change of sense (Brentano, who derives his theory from Mill except that he denies the necessity of a combination of ideas, and reduces a categorical to an existential judgment).

(f) It is a decision of the validity of an idea requiring will (Bergmann, following Brentano).

(g) Judgment (*Urtheil*) expresses that two ideas belong together: “by-judgment” (*Beurtheilung*) is the reaction of will expressing the validity or invalidity of the combination of ideas (Windelband, following Bergmann, but distinguishing the decision of validity from the judgment).

(h) Judgment is consciousness of the identity or difference and of the causal relations of the given; naming the actual combinations of the data, but also requiring *à priori* categories of the understanding, the notions of identity, difference, and causality, as principles of thought or laws, to combine the plurality of the given into a unity (Schuppe).

(i) Judgment is the act which refers an ideal content recognized as such to a reality beyond the act, predicating an idea of a reality, a what of a that; so that the subject is reality and the predicate the meaning of an idea, while the judgment refers the idea to reality by an identity of content (Bradley and Bosanquet).

(k) Judgment is an assertion of reality, requiring comparison and ideas which render it directly expressible in words (Hobhouse, mainly following Bradley).

These theories are of varying value in proportion to their proximity to Aristotle’s point that predication is about things, and to Mill’s point that judgments and propositions are about things, not about ideas. The essence of judgment is belief that something is (or is not) determined, either as existing (*e.g.*, “I am,” “A centaur is not”), or as something in particular (*e.g.*, “I am a man,” “I am not a monkey”). Neither Mill, however, nor any of the later logicians whose theories we have quoted, has been able quite to detach judgment from conception; they all suppose that an idea, or ideas, is a condition of all judgment. But judgment starts from sensation (*Empfindung*) and feeling (*Gefühl*), and not from idea (*Vorstellung*). When I feel pleased or pained, or when I use my senses to perceive a pressure, a temperature, a flavour, an odour, a colour, a sound, or when I am conscious of feeling and perceiving, I cannot resist the belief that something sensible is present; and this belief that something exists is already a judgment, a judgment of existence, and, so far as it is limited to sense without inference, a true judgment. It is a matter of words whether or not we should call this sensory belief a judgment; but it is no matter of choice to the logician,

who regards all the constituents of inference as judgments; for the fundamental constituents are sensory beliefs, which are therefore judgments in the logical sense. Sense is the evidence of inference; directly of analogical and inductive, directly or indirectly of deductive, inference; and therefore, if logic refuses to include sensory beliefs among judgments, it will omit the fundamental constituents of inference, inference will no longer consist of judgments but of sensory beliefs plus judgments, and the second part of logic, the logic of judgment, the purpose of which is to investigate the constituents of inference, will be like *Hamlet* without the Prince of Denmark. If, then, all the constituents of inference are judgments, there are judgments of sense (the *judicia sensus* of the Epicureans); and the evidence of the senses means that a judgment of sense is true, while a judgment of inference is true so far as it is directly or indirectly concluded from judgments of sense. Now a sensory judgment, *e.g.*, that a sensible pressure is existing, is explained by none of the foregoing theories, because it requires nothing but sensation and belief. It requires no will, but is usually involuntary, for the stimulus forces one's attention, which is not always voluntary: not all judgment then requires will, as Wundt supposes. It requires no reference to reality beyond the sensible pressure, so long as it is merely a belief that this exists without inference of the external stimulus or any inference at all: not all judgment then requires the reference of subjective to objective supposed by Ueberweg, or the consciousness of logical necessity supposed by Sigwart. It requires, in addition to the belief that something exists, no consideration as to whether the belief itself be true, because a man who feels pressure believes in the thing without further question about the belief: not all judgment then requires a decision of validity, as Bergmann supposes. It requires nothing beyond the sensation and belief in the given existence of the given pressure: not all judgment then requires categories of understanding, or notions of identity, difference, and causality, or even of existence, such as Schuppe supposes. It requires no comparison in order to express it in words, for a judgment need not be expressed, and a sensory judgment of pressure is an irresistible belief that a real pressure exists, without waiting for words, or for a comparison which is wanted not to make a sensation a judgment, but to turn a judgment into language: not all judgment then requires comparison with a view to its expression, as supposed by Hobhouse. Lastly, all the authors of the above-quoted theories err in supposing that all judgment requires conception; for even Mill thinks a combination of ideas necessary, and Brentano, who comes still nearer to the nature of sensory judgment when he says, "Every perception counts for a judgment," yet thinks that an idea is necessary at the same time in order to understand the thing judged. In reality, the sensation and the belief are sufficient; when I feel a sensible pressure, I cannot help believing in its reality, and therefore judging that it is real, without any *tertium quid*—an idea of pressure, or of existence, or of pressure existing—intervening between the sensation and the belief. Only after sensation has ceased does an idea, or representation of what is not presented, become necessary as a substitute for a sensation and as a condition not of the first judgment that there is, but of a second judgment that there was, something sensible. Otherwise there would be no judgment of sensible fact, for the first sensation would not give it, and the idea following the sensation would be still farther off. The sensory judgment then, which is nothing but a belief that something sensible exists at the moment of sense, is a proof that not all judgment requires conception, or synthesis or analysis of ideas, or decision about the content, or about the validity, of ideas, or reference

of an ideal content to reality, as commonly, though variously, supposed in the logic of our day. Curiously enough, the origin of the fallacy that conception is necessary to judgment lurks in the very tradition which recent logicians despise. By piecing together different statements of Aristotle, not he, but his interpreters, arrived at the imagination that we have first sensations, then ideas, then judgments, finally inferences. But had our logicians probed the foundation on which they unconsciously rest, they would have found that they are accepting without proof a fancied order of thought, not certified by consciousness, but arising from interpretation. Aristotle himself did not separate sensation from judgment. He defines sensation as a congenital critical power. He says, indeed, in the *De Interpretatione* that a name is the sign of a conception without the alternative of true or false which requires composition and division, and the addition of being or not-being. He says also in the *De Anima* that conception does not admit falsity, and that the alternative of false or true requires composition of conceptions. But he never identified combinations of conceptions with all judgment. On the contrary, he rightly recognized that there is a judgment in sense; that a sensation of its special object is always true; that sense is a kind of knowledge—knowledge of a particular, not of a universal; that sensations are the data of all inference; and that sense is the origin of science, though not science itself. Judgment of and from sense is the true tradition of Greek logic: to insert ideas between sense and judgment is the work of scholastic interpretation surviving, largely through Cartesian influences, in modern logic, because "the evil that men do lives after them."

Not, however, that all judgment is sensory: after the first judgments of sense follow judgments of memory, and memory requires ideas. Yet memory is not mere conception, as Aristotle, and Mill after him, have perceived. To remember, we must have a present idea; but we must also have a belief that the thing, of which the idea is a representation, was (or was not) determined; and this belief is the memorial judgment, *e.g.*, "Cæsar was murdered." Originally such judgments arise from sensory judgments followed by ideas, and are judgments of memory after sense that something sensible existed: afterwards come judgments of memory after inference. Finally, most judgments are inferential. These are conclusions which primarily are inferred from sensory and memorial judgments; and so far as inference starts from sense of something sensible in the present, and from memory after sense of something sensible in the past, and concludes similar things, inferential judgments are indirect beliefs in being and in existence beyond ideas. When from the sensible pressures between the parts of my mouth, which I feel and remember and judge that they exist and have existed, I infer another similar pressure (*e.g.*, of the food which presses and is pressed by my mouth in eating), the inferential judgment with which I conclude is a belief that the latter exists as well as the former (*e.g.*, the pressure of food without as well as the sensible pressures within). Inference, no doubt, is closely involved with conception. So far as it depends on memory, an inferential judgment presupposes memorial ideas in its data; and so far as it infers universal classes and laws, it produces general ideas. But even so the part played by conception is quite subordinate to that of belief. In the first place, the remembered datum, from which an inference of pressure starts, is not the conceived idea, but the belief that the sensible pressure existed. Secondly, the conclusion in which it ends is not the general idea of a class, but the belief that a class, represented by a general idea, exists, and is (or is not) otherwise determined (*e.g.*, that things pressing and pressed exist and move). Thirdly, there are questions which have never

been answered about inference. How far do we infer without memory and ideas, by combining sensory judgments present together (*e.g.*, from different pressures felt at once)? How far can we form ideas of the things which we judge inferentially to exist? We infer the existence of molecules, of æther, of God, and the inferential judgment produces some idea, but how far does it produce an adequate idea of the thing as we infer it? The answers to these questions are *desiderata* of modern logic. But whatever may be the answers, two things are certain about inferential judgment: one, that when inference is based on sense and memory, inferential judgment starts from a combination of sensory and memorial judgments, both of which are beliefs that things exist; the other, that in consequence inferential judgment is a belief that similar things exist. There are thus three primary judgments: judgments of sense, of memory after sense, and of inference from sense. All these are beliefs in being and existence, and this belief is first in sense, and afterwards transferred to memory and inference. Moreover, it is transferred in the same irresistible way: frequently we cannot help either feeling pressure, or remembering it, or inferring it; and as there are involuntary sensation and attention, so there are involuntary memory and inference. Again, in a primary judgment existence need not be expressed; but if expressed, it may be expressed either by the predicate, *e.g.*, "I exist," or by the subject, *e.g.*, "I who exist think." There are indeed differences between primary judgments, in that the sensory is a belief in present, the memorial in past, and the inferential in present, past, and future existence. But these differences in detail do not alter the main point that all these are beliefs in the existing, in the real as opposed to the ideal, in actual things which are not ideas. A primary judgment does not always even require an idea, because sensation produces judgments prior to any ideas, and inference produces judgments about things prior to ideas of those things. Memory, it is true, requires ideas, yet it is a belief in things; and inference from sense and memory concludes, not from ideas, but from sensory and memorial judgments which are beliefs in things, and with an inferential judgment which is a belief in things. In short, a primary judgment is a belief in something existing apart from our idea of it; and not because we have an idea of it, or by comparing an idea with, or referring an idea to, reality; but because we have a sensation of it, or a memory of it, or an inference of it. Sensation, not conception, is the origin of judgment.

(2) *Different Significations of Being in different Kinds of Judgment.*—As Aristotle remarked both in the *De Interpretatione* and in the *Sophistici Elenchi*, "not-being is thinkable" does not mean "not-being exists." In the latter treatise he added that it is a *fallacia a dicto secundum quid ad dictum simpliciter* to argue from the former to the latter; "for," as he says, "it is not the same thing to be something and to exist absolutely." Without realizing their debt to tradition, Herbart, Mill, and recently Sigwart, have repeated Aristotle's separation of the copula from the verb of existence, as if it were a modern discovery that "is" is not the same as "exists." It may be added that they do not quite realize what the copula exactly signifies: it does not signify existence, but it does signify a fact, namely, that something is (or is not) determined, either absolutely in a categorical judgment, or conditionally in a conditional judgment. Now we have seen that all primary judgments signify more than this fact; they are also beliefs in the existence of the thing signified by the subject. But, in the first place, primary judgments signify this existence never by the copula, but sometimes by the predicate, and sometimes by the subject; and, secondly, it does not follow that all

judgments whatever signify existence. Besides inference of existence there is inference of non-existence, of things inconsistent with the objects of primary judgments. Hence secondary judgments, which no longer contain a belief that the thing exists, *e.g.*, the judgment, "not-being is thinkable," cited by Aristotle; the judgment, "A square circle is impossible," cited by Herbart; the judgment, "A centaur is a fiction of the poets," cited by Mill. These secondary judgments of non-existence are partly like and partly unlike primary judgments of existence. They resemble them in that they are beliefs in being signified by the copula. They are beliefs in things of a sort; for, after all, ideas and names are things; their objects, even though non-existent, are at all events things conceivable or nameable; and therefore we are able to make judgments that things, non-existent but conceivable or nameable, are (or are not) determined in a particular manner. Thus the judgment about a centaur is the belief, "A conceivable centaur is a fiction of the poets," and the judgment about a square circle is the belief, "A so-called square circle is an impossibility." But though beliefs that things of some sort are (or are not) determined, these secondary judgments fall short of primary judgments of existence. Whereas in a primary judgment there is a further belief, signified by subject or predicate, that the thing is an existing thing in the sense of being a real thing (*e.g.*, a man), different from the idea of it as well as from the name for it; in a secondary judgment there is no further belief that the thing has any existence beyond the idea (*e.g.*, a centaur), or even beyond the name (*e.g.*, a square circle): though the idea or name exists, there is no belief that the thing conceived or named exists. Starting, then, from this fundamental distinction between judgments of existence and judgments of non-existence, we may hope to steer our way between two extreme views which emanate from two important thinkers, each of whom has produced a flourishing school of psychological logic.

On the one hand, early in the 19th century Herbart started the view that a categorical judgment is never a judgment of existence, but always hypothetical; on the other hand, in the latter part of the century Brentano started the view that all categorical judgments are existential. The truth lies between these contraries. The view of Herbart and his school is contradicted by our primary judgments of and from sense, in which we cannot help believing existence; and it gives an inadequate account even of our secondary judgments in which we no longer indeed believe existence, but do frequently believe that a non-existent thing is (or is not) somehow determined unconditionally. It is true, as Herbart says, that the judgment, "A square circle is an impossibility," does not contain the belief, "A square circle is existent"; but when he goes on to argue that it means, "If a square circle is thought, the conception of impossibility must be added in thought," he falls into a *non-sequitur*. To be categorical, a judgment does not require a belief in existence, but only that something, existent or not, is (or is not) determined; and there are two quite different attitudes of mind even to a non-existent thing, such as a square circle, namely, unconditional and conditional belief. The judgment, "A non-existent but so-called square circle is an impossibility," is an unconditional, or categorical judgment of non-existence, quite different from any hypothetical judgment, which depends on the conditions "if it is thought," or "if it exists," or any other "if." On the other hand, the view of Brentano and his school is contradicted by these very categorical judgments of non-existence; and while it applies only to categorical judgments of existence, it does so inadequately. To begin with the latter objection, Brentano proposed to change the four

Aristotelian forms of judgment, A, E, I, O, into the following existential forms:—

- A. "There is not an immortal man."
- E. "There is not a live stone."
- I. "There is a sick man."
- O. "There is an unlearned man."

This reconstruction, which merges subject and predicate in one expression, in order to combine it with the verb of existence, is repeated in similar proposals of recent English logicians. Venn, in his *Symbolic Logic*, proposes the four forms, $x\bar{y}=0, xy=0, xy>0, x\bar{y}>0$ (where \bar{y} means "not- y "), but only as alternative to the ordinary forms. Bradley says that "'S-P is real' attributes S-P, directly or indirectly, to the ultimate reality," and agrees with Brentano that "'is' never stands for anything but 'exists'"; while Bosanquet, who follows Bradley, goes so far as to define a categorical judgment as "that which affirms the existence of its subject, or, in other words, asserts a fact." Now, it is true that our primary judgments do contain a belief in existence; but they do not all contain it in the same way, but are beliefs sometimes that something is determined as existing, and sometimes that something existing is particularly determined. Brentano's forms do not express such a judgment of existence, as "All existing men are mortal." Nor does Bradley's form, "Reality includes S-P." Metaphysically, all realities are parts of one ultimate reality; but logically, even philosophers think more often only of finite realities, existing men, dogs, horses, &c.; so that the normal form of a judgment of existence is either "S is a real P," or "A real S is P." Hence the reconstruction of all categorical judgments by merging subject and predicate, either on Brentano's or on Bradley's plan, is a misrepresentation even of normal categorical judgments of existence. Secondly, it is much more a misrepresentation of categorical judgments of non-existence. No existential form suits a judgment such as "A centaur is a fiction," when we do not believe that there is a centaur, or that reality includes a centaur. As Mill pointed out, it cannot be implied that a centaur exists, since the very thing asserted is that the thing has no real existence. In a correspondence with Mill, Brentano rejoined that the centaur exists in imagination; Bradley says, "inside our heads." According to one, then, the judgment becomes "There is an imaginary centaur"; according to the other "Reality includes an imaginary centaur." The rejoinder, however, though partly true, is not to the point. The idea of the centaur does exist in our imagination, and inside our heads, and the name of it in our mouths. But the point is that the centaur conceived and named does not exist beyond the idea of it and the name for it; it is not, like a man, a real thing which is neither the idea of it nor the name for it; it is not an existing thing in the ordinary sense. Accordingly, no amount of subtlety will remove the difference between a categorical judgment of existence, e.g., "An existing man is mortal," and a categorical judgment of non-existence, e.g., "A conceivable centaur is a fiction," because in the former we believe and mean that the thing exists beyond the idea, and in the latter we do not. If, contrary to usage, we choose to call the latter a judgment of existence, there is no use in quarrelling about words; but we must insist that new terms must in that case be invented to express so fundamental a difference as that between judgments about real men and judgments about ideal centaurs. So long, however, as we use words in the natural sense, and call the former judgments of existence, and the latter judgments of non-existence, then "is" will not be, as Bradley supposes, the same as "exists," for we use "is" in both judgments, but "exists" only in the first kind. Bosanquet's definition of a categorical judgment contains

a similar confusion. To assert a fact and to affirm the existence of a subject are not, as he makes out, the same thing: a judgment often asserts a fact and denies existence in the same breath, e.g., "Jupiter is non-existent." Here, as usual in logic, tradition is better than innovation. All categorical judgment is an unconditional belief in the fact, signified by the copula, that a thing of some sort is (or is not) determined; but some categorical judgments are also beliefs that the thing is an existing thing, signified by the subject or by the predicate, while others are not beliefs that the thing exists at all, but are only beliefs in something conceivable, or nameable, or in something or other, without particularizing what. Judgment then always signifies being, but not always existence.

(3) *Particular and Universal Judgments.*—Aristotle, by distinguishing affirmative and negative, particular and universal, made the fourfold classification of judgments, A, E, I, and O, the foundation both of opposition and of inference. With regard to inference, he remarked that a universal judgment means by "all," not every individual we know, but every individual absolutely; so that, when it becomes a major premiss, we know in it every individual universally, not individually, and often do not know a given individual individually until we add a minor premiss in a syllogism. Whereas, then, a particular judgment is a belief that some, a universal judgment is a belief that all the individuals of a kind, or total of similar individuals, are similarly determined, whether they are known or unknown individuals. Now, as we have already seen, what is signified by the subject may be existing or not, and in either case a judgment remains categorical so long as it is a belief without conditions. Thus, "Some existing men are poets," "All existing men are mortal," "Some conceivable centaurs are human in their forequarters," "All conceivable centaurs are equine in their hindquarters," are all categorical judgments. Nevertheless these obvious applications of Aristotelian traditions have been recently challenged, especially by Sigwart, who holds in his *Logic* (secs. 27, 36) that while a particular is a categorical judgment of existence, a universal is hypothetical, on the ground that it does not refer to a definite number of individuals, or to individuals at all, but rather to general ideas, and that the appropriate form of "all M is P" is "if anything is M it is P." This view, which has influenced not only German but also English logicians, such as Venn, Bradley, and Bosanquet, destroys the fabric of inference, and reduces scientific laws to mere hypotheses. In reality, however, particular and universal judgments are too closely connected to have such different imports. In opposition, a categorical particular is the contradictory of a universal, which is also categorical, not hypothetical, e.g., "not all M is P" is the contradictory of "all M is P," not of "if anything is M it is P." In inference, a particular is an example of a universal, which in its turn may become a particular example of a higher universal. For instance, in the history of mechanics it was first inferred from some that all terrestrial bodies gravitate, and then from these as some that all ponderable bodies, terrestrial and celestial, gravitate. How absurd to suppose that here we pass from a particular categorical to a universal hypothetical, and then treat this very conclusion as a particular categorical to pass to a higher universal hypothetical! Sigwart, indeed, is deceived both about particulars and universals. On the one hand, some particulars are not judgments of existence, e.g., "some imaginary deities are goddesses"; on the other hand, some universals are not judgments of non-existence, e.g., "every existing man is mortal." Neither kind is always a judgment of existence, but each is sometimes the one and sometimes the other. In no

case is a universal hypothetical, unless we think it under a condition; for in a universal judgment about the non-existing, *e.g.*, about all conceivable centaurs, we do not think, "If anything is a centaur," because we do not believe that there are any; and in a universal judgment about the existent, *e.g.*, about all existing men, we do not think, "If anything is a man," because we believe that there is a whole class of men existing at different times and places. The cause of Sigwart's error is his misconception of "all." So far as he follows Aristotle in saying that "all" does not mean a definite number of individuals he is right; but when he says that we mean no individuals at all he leaves Aristotle and goes wrong. By "all" we mean every individual whatever of a kind; and when from the experience of sense and memory we start with particular judgments of existence, and infer universal judgments of existence and scientific laws, we further mean those existing individuals which we have experienced, and every individual whatever of the kind which exists. We mean neither a definite number of individuals, nor yet an infinite number, but an incalculable number, whether experienced or inferred to exist. We do not mean existing here and now, nor yet out of time and place, but at any time and place (*semper et ubique*)—past, present, and future being treated as simply existing, by what logicians used to call *suppositio naturalis*. We mean then by "all existing" every similar individual whatever, whenever, and wherever existing. Hence Sigwart is right in saying that "All bodies are extended" means "Whatever is a body is extended," but wrong in identifying this form with "If anything is a body it is extended." "Whatever" is not "if anything." For the same reason it is erroneous to confuse "all existing" with a general idea. Nor does the use of abstract ideas and terms make any difference. When Bosanquet says that in "Heat is a mode of motion" there is no reference to individual objects, but "a pure hypothetical form which absolutely neglects the existence of objects," he falls far short of expressing the nature of this scientific judgment, for in his *Theory of Heat* Clerk Maxwell describes it as "believing heat as it exists in a hot body to be in the form of kinetic energy." As Bacon would say, it is a belief that all individual bodies *qua* hot are individually but similarly moving in their particles. When, again, Bradley and Bosanquet speak of the universal as if it always meant one ideal content referred to reality, they forget that in universal judgments of existence, such as "All men existing are mortal," we believe that every individually existing man dies his own death individually, though similarly to other men; and that we are thinking neither of ideas nor of reality, but of all existent individual men being individually but similarly determined. A universal is indeed one whole; but it is one whole of many similars, which are not the same with one another. This is indeed the very essence of distribution, that a universal is predicable, not singly or collectively, but severally and similarly of each and every individual of a kind, or total of similar individuals. So also the essence of a universal judgment is that every individual of the kind is severally but similarly determined. Finally, such a judgment is often a judgment of existence; but whether it is so or not it remains categorical, so long as it introduces no hypothetical antecedent about the existence of the thing signified by the subject. It is true that even in universal judgments of existence there is often a hypothetical element; for example, "All men are mortal" contains a doubt whether every man whatever, whenever, and wherever existing, must die. But this is only a doubt whether all the things signified by the subject are similarly determined as signified by the predicate, and not a doubt whether there are such things at all.

Hence the hypothetical element is not a hypothetical antecedent "If anything is a man," but an uncertain conclusion that "All existing men are mortal." In other words, a categorical universal is often problematic, but a problematic is not the same as a hypothetical judgment.

(4) *The Judgment and the Proposition.*—Judgment in general is the mental act of believing that something is (or is not) determined. A proposition is the consequent verbal expression of such a belief, and consists in asserting that the thing as signified by the subject is (or is not) determined as signified by the predicate. But the expression is not necessary. Sensation irresistibly produces a judgment of existence without needing language. Children think long before they speak; and indeed, as mere vocal sounds are not speech, and as the apprehension that a word signifies a thing is a judgment, judgment is originally not an effect, but a cause of significant language. At any rate, even when we have learnt to speak, we do not express all we think, as we may see not only from the fewness of words known to a child, but also from our own adult consciousness. The principle of language is to speak only so far as to understand and be understood. Hence speech is only a curtailed expression of thought. Sometimes we express a whole judgment by one word, *e.g.*, "Fire!" or by a phrase, *e.g.*, "What a fire!" and only usually by a proposition. But even the normal proposition in the full logical form *tertiū adjacentis*, with subject, predicate, and copula, is seldom a complete expression of the judgment. The consequence is that the proposition, being different from a judgment, arising after judgment, and remaining an imperfect copy of judgment, is only a superficial evidence of its real nature. Fortunately, we have more profound evidences, and at least three evidences in all: the linguistic expression of belief in the proposition; the consciousness of what we mentally believe; and the analysis of reasoning, which shows what we must believe, and have believed, as data for inference. In these ways we find that a judgment is both different from, and more than, a proposition. But recent logicians, although they perceive the difference, nevertheless tend to make the proposition the measure of the judgment. This makes them omit sensory judgments, and count only those which require ideas, and even general ideas expressed in general terms. Sigwart, for example, gives as instances of our most elementary judgments, "This is Socrates," "This is snow,"—beliefs in things existing beyond ourselves which require considerable inferences from many previous judgments of sense and memory. Worse still, logicians seem unable to keep the judgment apart from the proposition. Herbart says that the judgment "A is B" does not contain the usually added thought that A is, because there is no statement of A's existence; as if that mattered. So Sigwart, in order to reduce universals to hypotheticals, while admitting that existence is usually thought, argues that it is not stated in the universal judgment; so also Bosanquet. But in the judgment the point is not what we state, but what we think; and so long as the existence of A is added in thought, the judgment in question must contain the thought that A exists as well as that A is B, and therefore is a judgment that something is determined both as existing and in a particular manner. The statement only affects the proposition; and whenever we believe the existence of the thing, the belief in existence is part of the judgment thought, whether it is part of the proposition stated or not.

Here Sir William Hamilton did a real service to logic in pointing out that "Logic postulates to be allowed to state explicitly in language all that is implicitly contained in the thought." Not that men should or can carry this logical postulate out in ordinary life; but it is necessary in

the logical analysis of judgments, and yet logicians neglect it. This is why they confuse the categorical and the universal with the hypothetical. Taking the carelessly expressed propositions of ordinary life, they do not perceive that similar judgments are often differently expressed, e.g., "I, being a man, am mortal," and "If I am a man, I am mortal"; and conversely, that different judgments are often similarly expressed. In ordinary life we may say, "All men are mortal," "All centaurs are figments," "All square circles are impossibilities," "All candidates arriving five minutes late are fined" (the last proposition being an example of the identification of categorical with hypothetical in Keynes's *Formal Logic*). But of these universal propositions the first imperfectly expresses a categorical belief in existing things, the second in thinkable things, and the third in nameable things, while the fourth is a slipshod categorical expression of the hypothetical belief, "If any candidates arrive late they are fined." The four judgments are different, and therefore logically the propositions fully expressing them are also different. The judgment, then, is the measure of the proposition, not the proposition the measure of the judgment. On the other hand, we may go too far in the opposite direction, as Hamilton did in proposing the universal quantification of the predicate. If the quantity of the predicate were always thought, it ought logically to be always stated. But we only sometimes think it. Usually we leave the predicate indefinite, because, as long as the thing in question is (or is not) determined, it does not matter about other things, and it is vain for us to try to think all things at once. It is remarkable that in *Barbara*, and therefore in deducing lower from higher laws in science, to think the quantity of the predicate is not to the point either in the premisses or in the conclusion; so that to quantify the propositions, as Hamilton proposes, would be to express more than a rational man thinks and judges. In judgments, and therefore in propositions, indefinite predicates are the rule, quantified predicates the exception. It follows also that a normal judgment is not an equation. The symbol of equality (=) is not the same as the copula (is); it means "is equal to," where "equal to" is part of the predicate, leaving "is" as the copula. Now, in all judgment we think "is," but in few judgments predicate "equal to." In quantitative judgments we may think $x = y$, or, as Boole proposes, $x = vy = \frac{0}{0}y$, or, as Jevons proposes, $x = xy$, or, as Venn proposes, x which is not $y = 0$; and equational symbolic logic is useful whenever we think in this quantitative way. But it is a byway of thought. In most judgments all we believe is that x is (or is not) y , that a thing is (or is not) determined, and that the thing signified by the subject is a thing signified by the predicate, but not that it is the only thing, or equal to everything signified by the predicate. The symbolic logic, which confuses "is" with "is equal to," having introduced a particular kind of predicate into the copula, falls into the mistake of reducing all predication to the one category of the quantitative; whereas it is more often in the substantial, e.g., "I am a man," not "I am equal to a man," or in the qualitative, e.g., "I am white," not "I am equal to white," or in the relative, e.g., "I am born in sin," not "I am equal to born in sin." Predication, as Aristotle saw, is as various as the categories of being. Finally, the great difficulty of the logic of judgment is to find the mental act behind the linguistic expression, to ascribe to it exactly what is thought, neither more nor less and to apply the judgment thought to the logical proposition, without expecting to find it in ordinary propositions. Beneath Hamilton's postulate there is a deeper principle of logic—*A rational being*

thinks only to the point, and speaks only to understand and be understood.

§ 3. INFERENCE.

(1) *False Views of Syllogism arising from False Views of Judgment.*—The false views of judgment, which we have been examining, have led to false views of inference. On the one hand, having reduced categorical judgments to an existential form, Brentano proposes to reform the syllogism, with the results that it must contain four terms, of which two are opposed and two appear twice; that, when it is negative, both premisses are negative; and that, when it is affirmative, one premiss, at least, is negative. In order to infer the universal affirmative that every professor is mortal because he is a man, Brentano's existential syllogism would run as follows:—

There is not a not-mortal man.
There is not a not-human professor.
∴ There is not a not-mortal professor.

On the other hand, if on the plan of Sigwart categorical universals were reducible to hypotheticals, the same inference would be a pure hypothetical syllogism, thus:—

If anything is a man it is mortal.
If anything is a professor it is a man.
∴ If anything is a professor it is mortal.

But both these unnatural forms, which are certainly not analyses of any conscious process of categorical reasoning, break down at once, because they cannot explain those moods in the third figure, e.g., *Darapti*, which reason from universal premisses to a particular conclusion. Thus, in order to infer that some wise men are good from the example of professors, Brentano's syllogism would be the following *non-sequitur*:—

There is not a not-good professor.
There is not a not-wise professor.
There is a wise good (*non-sequitur*).

So Sigwart's syllogism would be the following *non-sequitur*:—

If anything is a professor, it is good.
If anything is a professor, it is wise.
Something wise is good (*non-sequitur*).

But, as by the admission of both logicians these reconstructions of *Darapti* are illogical, it follows that their respective reductions of categorical universals to existentials and hypotheticals are false, because they do not explain an actual inference. Sigwart does not indeed shrink from this and greater absurdities; he reduces the first figure to the *modus ponens* and the second to the *modus tollens* of the hypothetical syllogism, and then, finding no place for the third figure, denies that it can infer necessity; whereas it really infers the necessary consequence of particular conclusions. But the greatest absurdity is that, if all universals were hypothetical, *Barbara* in the first figure would become a purely hypothetical syllogism—a consequence which seems innocent enough until we remember that all universal affirmative conclusions in all sciences would with their premisses dissolve into mere hypothesis. No logic can be sound which leads to the following analysis:—

If anything is a body it is extended.
If anything is a planet it is a body.
∴ If anything is a planet it is extended.

Sigwart, indeed, has missed the essential difference between the categorical and the hypothetical construction of syllogisms. In a categorical syllogism of the first figure, the major premiss, "Every M whatever is P," is a universal, which we believe on account of previous evidence without any condition about the thing signified by the subject M, which we simply believe sometimes to be existent (e.g., "Every man existent"), and sometimes

not (e.g., "Every centaur conceivable"); and the minor premiss, "S is M," establishes no part of the major, but adds the evidence of a particular not thought of in the major at all. But in a hypothetical syllogism of the ordinary mixed type, the first or hypothetical premiss is a conditional belief, e.g., "If anything is M it is P," containing a hypothetical antecedent, "If anything is M," which is sometimes a hypothesis of existence (e.g., "If anything is an angel"), and sometimes a hypothesis of fact (e.g., "If an existing man is wise"); and the second premiss or assumption, "Something is M," establishes part of the first, namely, the hypothetical antecedent, whether as regards existence (e.g., "Something is an angel"), or as regards fact (e.g., "This existing man is wise"). These very different relations of premisses are obliterated by Sigwart's false reduction of categorical universals to hypotheticals. But even Sigwart's errors are outdone by Lotze, who not only reduces "Every M is P" to "If S is M, S is P," but proceeds to reduce this hypothetical to the disjunctive, "If S is M, S is P¹ or P² or P³," and finds fault with the Aristotelian syllogism because it contents itself with inferring "S is P" without showing what P. Now there are occasions when we want to reason in this disjunctive manner, to consider whether S is P¹ or P² or P³, and to conclude that "S is a particular P"; but ordinarily all we want to know is that "S is P"; e.g., in arithmetic, that 2+2 are 4, not any particular 4, and in life that all our contemporaries must die, without enumerating all their particular sorts of deaths. Lotze's mistake is the same as that of Hamilton about the quantification of the predicate, and that of those symbolists who held that reasoning ought always to exhaust all alternatives by equations. It is the mistake of exaggerating exceptional into normal forms of thought, and ignoring the principle that a rational being thinks only to the point.

(2) *Quasi-syllogisms*.—Besides reconstructions of the syllogistic fabric, we find in recent logic attempts to extend the figures of the syllogism beyond the syllogistic rules. An old error that we may have a valid syllogism from merely negative premisses (*ex omnibus negativis*), long ago answered by Alexander and Boethius, is now revived by Lotze, Jevons, and Bradley, who do not perceive that the supposed second negative is really an affirmative containing a "not" which can only be carried through the syllogism by separating it from the copula and attaching it to one of the extremes, thus:—

The just are not unhappy (*negative*).
 The just are not-recognized (*affirmative*).
 ∴ Some not-recognized are not unhappy (*negative*).

Here the minor being the infinite term "not-recognized" in the conclusion, must be the same term also in the minor premiss. Schuppe, however, who is a fertile creator of quasi-syllogisms, has managed to invent some examples from two negative premisses of a different kind:—

$\begin{array}{l} (1) \\ \text{No N is P.} \\ \text{S is not M.} \\ \therefore \text{Neither S nor M} \\ \text{is P.} \end{array}$	$\begin{array}{l} (2) \\ \text{No M is P.} \\ \text{S is not M.} \\ \therefore \text{S may be P.} \end{array}$	$\begin{array}{l} (3) \\ \text{No P is M.} \\ \text{S is not M.} \\ \therefore \text{S may be P.} \end{array}$
--	--	--

But (1) concludes with a mere repetition, (2) and (3) with a contingent "may be," which, as Aristotle says, also "may not be," and therefore *nihil certo colligitur*. The same answer applies to Schuppe's supposed syllogisms from two particular premisses:—

$\begin{array}{l} (1) \\ \text{Some M is P.} \\ \text{Some S is M.} \\ \therefore \text{Some S may be P.} \end{array}$	$\begin{array}{l} (2) \\ \text{Some M is P.} \\ \text{Some M is S.} \\ \therefore \text{Some S may be P.} \end{array}$
--	--

The only difference between these and the previous examples (2) and (3) is that, while those break the rule against two negative premisses, these break that against

undistributed middle. Equally fallacious are two other attempts of Schuppe to produce syllogisms from invalid moods:—

$\begin{array}{l} (1) \text{ 1st Fig.} \\ \text{All M is P.} \\ \text{No S is M.} \\ \therefore \text{S may be P.} \end{array}$	$\begin{array}{l} (2) \text{ 2nd Fig.} \\ \text{P is M.} \\ \text{S is M.} \\ \therefore \text{S is partially identical with P.} \end{array}$
---	---

In the first the fallacy is the indifferent contingency of the conclusion caused by the *non-sequitur* from a negative premiss to an affirmative conclusion; while the second is either a mere repetition of the premisses if the conclusion means "S is like P in being M," or, if it means "S is P," a *non-sequitur* on account of the undistributed middle. It must not be thought that this trifling with logical rules has no effect. The last supposed syllogism, namely, that having two affirmative premisses, and entailing an undistributed middle in the second figure, is accepted by Wundt under the title "Inference by Comparison" (*Vergleichungsschluss*), and is supposed by him to be useful for abstraction and subsidiary to induction, and by Bosanquet to be useful for analogy. Wundt, for example, proposes the following premisses:—

Gold is a shining, fusible, ductile, simple body.
 Metals are shining, fusible, ductile, simple bodies.

But to say from these premisses, "Gold and metal are similar in what is signified by the middle term," is a mere repetition of the premisses; to say, further, that "Gold may be a metal" is a *non-sequitur*, because, the middle being undistributed, the logical conclusion is the contingent "Gold may or may not be a metal," which leaves the question quite open, and therefore there is no syllogism. Wundt, who is again followed by Bosanquet, also supposes another syllogism in the third figure, under the title of "Inference by Connexion" (*Verbindungsschluss*), to be useful for induction. He proposes, for example, the following premisses:—

Gold, silver, copper, lead, are fusible.
 Gold, silver, copper, lead, are metals.

Here there is no syllogistic fallacy in the premisses; but the question is what syllogistic conclusion can be drawn, and there is only one which follows without an illicit process of the minor, namely, "Some metals are fusible." The moment we stir a step farther with Wundt in the direction of a more general conclusion (*ein allgemeinerer Satz*), we cannot infer from the premisses the conclusion desired by Wundt, "Metals and fusible are connected"; nor can we infer "All metals are fusible," nor "Metals are fusible," nor "Metals may be fusible," nor "All metals may be fusible," nor any assertory conclusion, determinate or indeterminate, but the indifferent contingent, "All metals may or may not be fusible," which leaves the question undecided, so that there is no syllogism. We do not mean that in Wundt's supposed "inferences of relation by comparison and connexion" the premisses are of no further use; but those of the first kind are of no syllogistic use in the second figure, and those of the second kind of no syllogistic use beyond particular conclusions in the third figure. What they really are in the inferences proposed by Wundt is not premisses for syllogism, but data for induction parading as syllogism. We must pass the same sentence on Lotze's attempt to extend the second figure of the syllogism for inductive purposes, thus:—

S is M.
 Q is M.
 R is M.
 ∴ Every Σ, which is common to S, Q, R, is M.

We could not have a more flagrant abuse of the rule *Ne esto plus minusque in conclusione quam in premissis*. As we see from Lotze's own defence, the conclusion cannot be

drawn without another premiss or premisses to the effect that "S, Q, R, are Σ, and Σ is the one real subject of M." But how is all this to be got into the second figure? Again, Wundt and B. Erdmann propose new moods of syllogism with convertible premisses, containing definitions and equations. Wundt's *Logic* has the following forms:—

(1) 1st Fig. Only M is P. No S is M. ∴ No S is P.	(2) 2nd Fig. $x=y.$ $z=y.$ ∴ $x=z.$	(3) 3rd Fig. $y=x.$ $y=z.$ ∴ $x=z.$
--	--	--

Now, there is no doubt that, especially in mathematical equations, universal conclusions are obtainable from convertible premisses expressed in these ways. But the question is how the premisses must be thought, and they must be thought in the converse way to produce a logical conclusion. Thus, we must think in (1) "All P is M" to avoid illicit process of the major, in (2) "All y is z" to avoid undistributed middle, in (3) "All x is y" to avoid illicit process of the minor. Indeed, it is the very essence of a convertible judgment to think it in both orders, and especially to think it in the order necessary to an inference from it. Accordingly, however expressed, the syllogisms quoted above are, as thought, ordinary syllogisms, (1) being *Camestres* in the second figure, (2) and (3) *Barbara* in the first figure. Aristotle, indeed, was as well aware as German logicians of the force of convertible premisses; but he was also aware that they require no special syllogisms, and made it a point that, in a syllogism from a definition, the definition is the middle, and the *definitum* the major in a convertible major premiss of *Barbara* in the first figure, e.g. :—

The interposition of an opaque body is (essentially) deprivation of light.
 The moon suffers the interposition of the opaque earth.
 ∴ The moon suffers deprivation of light.

It is the same with all the recent attempts to extend the syllogism beyond its rules, which are not liable to exceptions, because they follow from the nature of syllogistic inference from universal to particular. To give the name of syllogism to inferences which infringe the general rules against undistributed middle, illicit process, two negative premisses, *non-sequitur* from negative to affirmative, and the introduction of what is not in the premisses into the conclusion, and which consequently infringe the special rules against affirmative conclusions in the second figure, and against universal conclusions in the third figure, is to open the door to fallacy, and at best to confuse the syllogism with other kinds of inference, without enabling us to understand any one kind.

(3) *Analytic and Synthetic Deduction.*—Alexander the Commentator defined synthesis as a progress from principles to consequences, analysis as a regress from consequences to principles; and Latin logicians preserved the same distinction between the *progressus a principiis ad principia*, and the *regressus a principiatis ad principia*. No distinction is more vital in the logic of inference in general and of scientific inference in particular; and yet none has been so little understood, because, though analysis is the more usual order of discovery, synthesis is that of instruction, and therefore, by becoming more familiar, tends to replace and obscure the previous analysis. The distinction, however, did not escape Aristotle, who saw that a progressive syllogism can be reversed thus:—

1. <i>Progression.</i> All M is P. All S is M. ∴ All S is P.	(1) All P is M. All S is P. ∴ All S is M.	2. <i>Regression.</i> (2) All S is P. All M is S. ∴ All M is P.
---	--	---

Proceeding from one order to the other, by converting one of the premisses, and substituting the conclusion as pre-

miss for the other premiss, so as to deduce the latter as conclusion, is what he calls circular inference; and he remarked that the process is fallacious unless it contains propositions which are convertible, as in mathematical equations. Further, he perceived that the difference between the progressive and regressive orders extends from mathematics to physics, and that there are two kinds of syllogism: one progressing *à priori* from real ground to consequent fact (*ὁ τοῦ διότι συλλογισμὸς*), and the other regressing *à posteriori* from consequent fact to real ground (*ὁ τοῦ ὅτι συλλογισμὸς*). For example, as he says, the sphericity of the moon is the real ground of the fact of its light waxing; but we can deduce either from the other, as follows:—

1. <i>Progression.</i> What is spherical waxes. The moon is spherical. ∴ The moon waxes.	2. <i>Regression.</i> What waxes is spherical. The moon waxes. ∴ The moon is spherical.
---	--

These two kinds of syllogism are synthesis and analysis in the ancient sense. Deduction is analysis when it is regressive from consequence to real ground, as when we start from the proposition that the angles of a triangle are equal to two right angles, and deduce analytically that therefore (1) they are equal to equal angles made by a straight line standing on another straight line, and (2) such equal angles are two right angles. Deduction is synthesis when it is progressive from real ground to consequence, as when we start from these two results of analysis as principles and deduce synthetically the proposition that therefore the angles of a triangle are equal to two right angles, in the order familiar to the student of Euclid. But the full value of the ancient theory of these processes cannot be appreciated until we recognize that as Aristotle planned them Newton used them. Much of the *Principia* consists of synthetical deductions from definitions and axioms. But the discovery of the centripetal force of the planets to the sun is an analytic deduction from the facts of their motion discovered by Kepler to their real ground, and is so stated by Newton in the first regressive order of Aristotle—P-M, S-P, S-M. Newton did indeed first show synthetically what kind of motions by mechanical laws have their ground in a centripetal force varying inversely as the square of the distance (all P is M); but his next step was, not to deduce synthetically the planetary motions, but to make a new start from the planetary motions as facts established by Kepler's laws and as examples of the kind of motions in question (all S is P); and then, by combining these two premisses, one mechanical and the other astronomical, he analytically deduced that these facts of planetary motion have their ground in a centripetal force varying inversely as the squares of the distances of the planets from the sun (all S is M). (See *Principia* I. prop. 2; 4 coroll. 6; III. Phænomena, 4-5; prop. 2.) What Newton did, in short, was to prove by analysis that the planets, revolving by Kepler's astronomical laws round the sun, have motions such as by mechanical laws are consequences of a centripetal force to the sun. This done, as the major is convertible, the analytic order—P-M, S-P, S-M—was easily inverted into the synthetic order—M-P, S-M, S-P; and in this progressive order the deduction as now taught begins with the centripetal force of the sun as real ground, and deduces the facts of planetary motion as consequences. Thereupon the Newtonian analysis, which preceded this synthesis, became forgotten; until at last Mill in his *Logic*, neglecting the *Principia*, had the temerity to distort Newton's discovery, which was really a pure example of analytic deduction, into a mere hypothetical deduction; as if the author of the saying "*Hypotheses non fingo*" started from the hypothesis of a centripetal force to the sun, and thence deductively explained the facts of planetary motion,

which reciprocally verified the hypothesis. This gross misrepresentation has made hypothesis a kind of logical fashion. Worse still, Jevons proceeded to confuse analytical deduction from consequence to ground with hypothetical deduction from ground to consequence under the common term "inverse deduction." Wundt attempts, but in vain, to make a compromise between the old and the new. He re-defines analysis in the very opposite way to the ancients; whereas they defined it as a regressive process from consequence to ground, according to Wundt it is a progressive process of taking for granted a proposition and deducing a consequence, which being true verifies the proposition. He then divides it into two species: one categorical, the other hypothetical. By the categorical he means the ancient analysis from a given proposition to more general propositions. By the hypothetical he means the new-fangled analysis from a given proposition to more particular propositions, *i.e.*, from a hypothesis to consequent facts. But his account of the first is imperfect, because in ancient analysis the more general propositions, with which it concludes, are not mere consequences, but the real grounds of the given proposition; while his addition of the second reduces the nature of analysis to the utmost confusion, because hypothetical deduction is progressive from hypothesis to consequent facts, whereas analysis is regressive from consequent facts to real ground. There is indeed a sense in which all inference is from ground to consequence, because it is from logical ground (*principium cognoscendi*) to logical consequence. But in the sense in which deductive analysis is opposed to deductive synthesis, analysis is deduction from real consequence as logical ground (*principiatum* as *principium cognoscendi*) to real ground (*principium essendi*), *e.g.*, from the consequential facts of planetary motion to their real ground in centripetal force to the sun. Hence Sigwart is undoubtedly right in distinguishing analysis from hypothetical deduction, for which he proposes the name "reduction." We have only further to add that many scientific discoveries about sound, heat, light, colour, and so forth, which it is the fashion to represent as hypotheses to explain facts, are really analytical deductions from the facts to their real grounds in accordance with mechanical laws. Recent logic does scant justice to scientific analysis.

(4) *Induction*.—As induction is the process from particulars to universals, it might have been thought that it would always have been opposed to syllogism, in which one of the rules is against using particular premisses to draw universal conclusions. Yet such is the passion for one type that from Aristotle's time till now constant attempts have been made to reduce induction to syllogism. Aristotle himself invented an inductive syllogism in which the major (P) is to be referred to the middle (M) by means of the minor (S), thus:—

A, B, C magnets (S) attract iron (P).
 A, B, C magnets (S) are all magnets whatever (M).
 ∴ All magnets whatever (M) attract iron (P).

As the second premiss is supposed to be convertible, he reduced the inductive to a deductive syllogism as follows:—

Every S is P. Every S is M (convertibly). ∴ Every M is P.	Every S is P. Every M is S. ∴ Every M is P.
---	---

In the reduced form the inductive syllogism was described by Aldrich as "*Syllogismus in Barbara cujus minor (i.e., every M is S) reticetur.*" Whately, on the other hand, proposed an inductive syllogism with the major suppressed, that is, instead of the minor premiss above, he supposed a major premiss, "Whatever belongs to A, B, C magnets belongs to all." Mill thereupon supposed a still more general premiss, an assumption of the uniformity of

nature. Since Mill's time, however, the logic of induction tends to revert towards syllogisms more like that of Aristotle. Jevons supposed induction to be inverse deduction, distinguished from direct deduction as analysis from synthesis, *e.g.*, as division from multiplication; but he really meant that it is a deduction from a hypothesis of the law of a cause to particular effects which, being true, verify the hypothesis. Sigwart declares himself in agreement with Jevons; except that, being aware of the difference between hypothetical deduction and mathematical analysis, and seeing that, whereas analysis (*e.g.*, in division) leads to certain conclusions, hypothetical deduction is not certain of the hypothesis, he arrives at the more definite view that induction is not analysis proper but hypothetical deduction, or "reduction," as he proposes to call it. Reduction he defines as "the framing of possible premisses for given propositions, or the construction of a syllogism when the conclusion and one premiss is given." On this view induction becomes a reduction in the form: all M is P (hypothesis), S is M (given), ∴ S is P (given). The views of Jevons and Sigwart are in agreement in two main points. According to both, induction, instead of inferring from A, B, C magnets the conclusion "Therefore all magnets attract iron," infers from the hypothesis, "Let every magnet attract iron," to A, B, C magnets, whose given attraction verifies the hypothesis. According to both, again, the hypothesis of a law with which the process starts contains more than is present in the particular data: according to Jevons, it is the hypothesis of a law of a cause from which induction deduces particular effects; and according to Sigwart, it is a hypothesis of the ground from which the particular data necessarily follow according to universal laws. Lastly, Wundt's view is an interesting piece of eclecticism, for he supposes that induction begins in the form of Aristotle's inductive syllogism, S-P, S-M, M-P, and becomes an inductive method in the form of Jevons's inverse deduction, or hypothetical deduction, or analysis, M-P, S-M, S-P. In detail, he supposes that, while an "inference by comparison," which he erroneously calls an affirmative syllogism in the second figure, is preliminary to induction, a second "inference by combination," which he erroneously calls a syllogism in the third figure with an indeterminate conclusion, is the inductive syllogism itself. This is like Aristotle's inductive syllogism in the arrangement of terms; but, while on the one hand Aristotle did not, like Wundt, confuse it with the third figure, on the other hand Wundt does not, like Aristotle, suppose it to be practicable to get inductive data so wide as the convertible premiss, "All S is M, and all M is S," which would at once establish the conclusion, "All M is P." Wundt's point is that the conclusion of the inductive syllogism is neither so much as all, nor so little as some, but rather the indeterminate "M and P are connected." The question therefore arises, how we are to discover "All M is P," and this question Wundt answers by adding an inductive method, which involves inverting the inductive syllogism in the style of Aristotle into a deductive syllogism from a hypothesis in the style of Jevons, thus:—

S is P. (1) S is M. ∴ M and P are connected.	Every M is P. (2) S is M. ∴ S is P.
--	---

He agrees with Jevons in calling this second syllogism analytical deduction, and with Jevons and Sigwart in calling it hypothetical deduction. It is, in fact, a common point of Jevons, Sigwart, and Wundt that the universal is not really a conclusion inferred from given particulars, but a hypothetical major premiss from which given particulars are inferred, and that this major contains pre-suppositions of causation not contained in the particulars.

It is noticeable that Wundt quotes Newton's discovery of the centripetal force of the planets to the sun as an instance of this supposed hypothetical, analytic, inductive method; as if Newton's analysis were a hypothesis of the centripetal force to the sun, a deduction of the given facts of planetary motion, and a verification of the hypothesis by the given facts, and as if such a process of hypothetical deduction could be identical with either analysis or induction. The abuse of this instance of Newtonian analysis betrays the whole origin of the current confusion of induction with deduction. One confusion has led to another. Mill confused Newton's analytical deduction with hypothetical deduction; and thereupon Jevons confused induction with both. The result is that both Sigwart and Wundt transform the inductive process of adducing particular examples to induce a universal law into a deductive process of presupposing a universal law as a ground to deduce particular consequences. But we can easily extricate ourselves from these confusions by comparing induction with different kinds of deduction. The point about induction is that it starts from experience, and that, though in most classes we can experience only some particulars individually, yet we infer all. Hence induction cannot be reduced to Aristotle's inductive syllogism, because experience cannot give the convertible premiss, "Every S is M, and every M is S"; that "All A, B, C are magnets" is, but that "All magnets are A, B, C" is not, a fact of experience. For the same reason induction cannot be reduced to analytical deduction of the second kind in the form, S-P, M-S, ∴ M-P; because, though both end in a universal conclusion, the limits of experience prevent induction from such inference as—

Every experienced magnet attracts iron.
 Every magnet whatever is every experienced magnet.
 ∴ Every magnet whatever attracts iron.

Still less can induction be reduced to analytical deduction of the first kind in the form—P-M, S-P, ∴ S-M, of which Newton has left so conspicuous an example in his *Principia*. As the example shows, that analytic process starts from the scientific knowledge of a universal and convertible law (every M is P, and every P is M), e.g., a mechanical law of all centripetal force, and ends in a particular application, e.g., this centripetal force of planets to the sun. But induction cannot start from a known law. Hence it is that Jevons, followed by Sigwart and Wundt, reduces it to deduction from a hypothesis in the form "Let every M be P, S is M, ∴ S is P." There is a superficial resemblance between induction and this hypothetical deduction. Both in a way use given particulars as evidence. But in induction the given particulars are the evidence by which we discover the universal, e.g., particular magnets attracting iron are the origin of an inference that all do; in hypothetical deduction, the universal is the evidence by which we explain the given particulars, as when we suppose undulating æther to explain the facts of heat and light. In the former process, the given particulars are the data from which we infer the universal; in the latter, they are only the consequent facts by which we verify it. Or rather, there are two uses of induction: inductive discovery before deduction, and inductive verification after deduction. But neither use of induction is the same as the deduction itself: the former precedes, the latter follows it. Lastly, the theory of Mill, though frequently adopted, e.g., by B. Erdmann, need not detain us long. Most inductions are made without any assumption of the uniformity of nature; for, whether it is itself induced, or *à priori*, or postulated, this like every assumption is a judgment, and most men are incapable of judgment on so universal a scale, when they are quite capable of induction. The fact is that the uniformity of nature stands to

induction as the axioms of syllogism do to syllogism; they are not premisses, but conditions of inference, which ordinary men use spontaneously, as was pointed out in *Physical Realism*, and afterwards in Venn's *Empirical Logic*. The axiom of contradiction is not a major premiss of a judgment: the *dictum de omni et nullo* is not a major premiss of a syllogism: the principle of uniformity is not a major premiss of an induction. Induction, in fact, is no species of deduction; they are opposite processes, as Aristotle regarded them except in the one passage where he was reducing the former to the latter, and as Bacon always regarded them. But it is easy to confuse them by mistaking examples of deduction for inductions. Thus Whewell mistook Kepler's inference that Mars moves in an ellipse for an induction, though it required the combination of Tycho's and Kepler's observations, as a minor, with the laws of conic sections discovered by the Greeks, as a major, premiss. Jevons, in his *Principles of Science*, constantly makes the same sort of mistake. For example, the inference from the similarity between solar spectra and the spectra of various gases on the earth to the existence of similar gases in the sun, is called by him an induction; but it really is an analytical deduction from effect to cause, thus:—

Such and such spectra are effects of various gases.
 Solar spectra are such spectra.
 ∴ Solar spectra are effects of those gases.

In the same way, to infer a machine from hearing the regular tick of a clock, to infer a player from finding a pack of cards arranged in suits, to infer a human origin of stone implements, and all such inferences from patent effects to latent causes, though they appear to Jevons to be typical inductions, are really deductions which, besides the minor premiss stating the particular effects, require a major premiss inducing the general kind of effects of a general kind of cause. B. Erdmann, again, has invented an induction from particular predicates to a totality of predicates which he calls "*ergänzende Induction*," giving as an example, "This body has the colour, extensibility, and specific gravity of magnesium; therefore it is magnesium." But this inference contains the tacit major, "What has a given colour, &c., is magnesium," and is a syllogism of recognition. A deduction is often like an induction, in inferring from particulars; the difference is that deduction combines a law in the major with the particulars in the minor premiss, and infers syllogistically that the particulars of the minor have the predicate of the major premiss, whereas induction uses the particulars simply as instances to generalize a law. An infallible sign of an induction is that the subject and predicate of the universal conclusion are merely those of the particular instances generalized; e.g., "These magnets attract iron, ∴ all do."

This brings us to another source of error. As we have seen, Jevons, Sigwart, and Wundt all think that induction contains a belief in causation, in a cause, or ground, which is not present in the particular facts of experience, but is contributed by a hypothesis added as a major premiss to the particulars in order to explain them by the cause or ground. Not so; when an induction is causal, the particular instances are already beliefs in particular causes, e.g., "My right hand is exerting pressure reciprocally with my left," "A, B, C magnets attract iron"; and the problem is to generalize these causes, not to introduce them. Induction is not introduction. It would make no difference to the form of induction, if, as Kant thought, the notion of causality is *à priori*; for even Kant thought that it is contained in experience. But whether Kant be right or wrong, Wundt and his school are decidedly wrong in supposing "supplementary notions which are not contained in experience itself, but are

gained by a process of logical treatment of this experience"; as if our belief in causality could be neither *à posteriori* nor *à priori*, and beyond experience wake up in a hypothetical major premiss of induction. Really, we first experience that particular causes have particular effects; then induce that causes similar to those have effects similar to these; finally, deduce that when a particular cause of the kind occurs it has a particular effect of the kind by synthetic deduction, and that when a particular effect of the kind occurs it has a particular cause of the kind by analytic deduction with a convertible premiss, as when Newton from planetary motions, like terrestrial motions, analytically deduced a centripetal force to the sun like centripetal forces to the earth. Moreover, causal induction is itself both synthetic and analytic: according as experiment combines elements into a compound, or resolves a compound into elements, it is the origin of a synthetic or an analytic generalization. Not, however, that all induction is causal; but where it is not, there is still less reason for making it a deduction from hypothesis. When from the fact that the many crows in our experience are black, we induce the probability that all crows whatever are black, the belief in the particulars is quite independent of this universal. How then can this universal be called, as Sigwart, for example, calls it, the ground from which these particulars follow? I do not believe that the crows I have seen are black because all crows are black, but *vice versa*. Sigwart simply inverts the order of our knowledge. In all induction, as Aristotle said, the particulars are the evidence, or ground of our knowledge (*principium cognoscendi*), of the universal. In causal induction, the particulars contain the cause, or ground of the being (*principium essendi*), of the effect, as well as the ground of our inducing the law. In all induction the universal is the conclusion, in none a major premiss, and in none the ground of either the being or the knowing of the particulars. Induction is simply generalization. It is not syllogism in the form of Aristotle's or Wundt's inductive syllogism, because, though starting only from some particulars, it concludes with a universal; it is not syllogism in the form called inverse deduction by Jevons, reduction by Sigwart, inductive method by Wundt, because it often uses particular facts of causation to infer universal laws of causation; it is not syllogism in the form of Mill's syllogism from a belief in uniformity of nature, because few men have believed in uniformity, but all have induced from particulars to universals. Bacon alone was right in altogether opposing induction to syllogism, and in finding inductive rules for the inductive process from particular instances of presence, absence in similar circumstances, and comparison. But how from some particulars of experience do we infer all universally? The answer to this question is still a *desideratum* of logic.

(5) *Inference in General.*—There are three types:—

(1) Syllogism.	(2) Induction.	(3) Analogy.
Every M is P.	S is P.	S ¹ is P.
S is M.	Every M is similar to S.	S ² is similar to S ¹ .
∴ S is P.	∴ Every M is P.	∴ S ² is P.

Different as they are, the three kinds have something in common: they are all processes from similar to similar; they are all processes from judgment to judgment, whether expressed in propositions or not; and, as a judgment is a belief in being, they are all processes from one belief in being to another. Inference, in short, is any process from a given judgment, or belief that something is (or is not) determined, to a concluding judgment, or belief that something else which is similar in one or more respects is (or is not) similarly determined. Nevertheless, simple as this account appears, it is opposed in every point to recent logic. In the first place, the point of Brad-

ley's logic is that "similarity is not a principle which works. What operates is identity, and that identity is a universal." This view makes inference easy: induction is all over before it begins; for, according to Bradley, "every one of the instances is already a universal proposition; and it is not a particular fact or phenomenon at all," so that the moment you observe that this magnet attracts iron, you *ipso facto* know that every magnet does so, and all that remains for deduction is to identify a second magnet as the same with the first, and conclude that it attracts iron. In dealing with Bradley's works we feel inclined to repeat what Aristotle says of the discourses of Socrates: they all exhibit excellence, cleverness, novelty, and inquiry, but their truth is a difficult matter; and the Socratic paradox that virtue is knowledge is not more difficult than the Bradleian paradox that as two different things are the same inference is identification. The basis of Bradley's logic is the fallacious dialectic of Hegel's metaphysics, founded on the supposition that two things, which are different, but have something in common, are the same. For example, according to Hegel, being and not-being are both indeterminate, and therefore the same. "If," says Bradley, "A and B, for instance, both have lungs or gills, they are so far the same." The answer to Hegel is that being and not-being are at most similarly indeterminate, and to Bradley that each animal has its own different lungs, whereby they are only similar. If they were the same, then in descending, two things, one of which has healthy and the other diseased lungs, would be the same; and in ascending, two things, one of which has lungs and the other has not, but both of which have life, *e.g.*, plants and animals, would be so far the same. There would be no limit to identity either downwards or upwards; so that a man would be the same as a man-of-war, and all things would be the same thing, and not different parts of one universe. But a thing which has healthy lungs and a thing which has diseased lungs are only similar individuals numerically different. Each individual thing is the same only with itself, although related to other things; and each individual of a class has its own individual, though similar, attributes. The consequence of this true metaphysics to logic is twofold: on the one hand, one singular or particular judgment, *e.g.*, "this magnet attracts iron," is not another, *e.g.*, "that magnet attracts iron, and neither is universal; on the other hand, a universal judgment, *e.g.*, "every magnet attracts iron," means, distributively, that each individual magnet exerts its individual attraction, though it is similar to other magnets exerting similar attractions. A universal is not "one identical point," but one distributive whole. Hence in a syllogism, a middle term, *e.g.*, magnets, is "absolutely the same," not in the sense of "one identical point" making each individual the same as any other, as Bradley supposes, but only in the sense of one whole class, or total of many similar individuals, *e.g.*, magnets, each of which is a magnet, not magnet in general. Hence also induction is a real process, because, when we know that this individual magnet attracts iron, we are very far from knowing that all alike do so similarly; and the question of inductive logic, how we get from some similars to all similars, remains, as before, a difficulty, but not to be solved by the fallacy that inference is identification.

Secondly, a subordinate point in Bradley's logic is that there are inferences which are not syllogisms; and this is true. But when he goes on to propose, as a complete independent inference, "A is to the right of B, B is to the right of C, therefore A is to the right of C," he confuses two different operations. When A, B, and C are objects of sense, their relative positions are matters, not of inference, but of observation; when they are not, there is

an inference, but a syllogistic inference with a major premiss, induced from previous observations, "whenever of three things the first is to the right of the second, and the second to the right of the third, the first is to the right of the third." To reply that this universal judgment is not expressed, or that its expression is cumbrous, is no answer, because, whether expressed or not, it is required for the thought. As Aristotle puts it, the syllogism is directed "not to the outer, but to the inner discourse," or as we should say, not to the expression but to the thought, not to the proposition but to the judgment, and to the inference not verbally but mentally. Bradley seems to suppose that the major premiss of a syllogism must be explicit, or else is nothing at all. But it is often thought without being expressed, and to judge the syllogism by its mere explicit expression is to commit an *ignoratio elenchi*; for it has been known all along that we express less than we think, and the very purpose of syllogistic logic is to analyse the whole thought necessary to the conclusion. In this syllogistic analysis two points must always be considered: one, that we usually use premisses in thought which we do not express; and the other, that we sometimes use them unconsciously, and therefore infer and reason unconsciously, in the manner excellently described by Zeller in his *Vorträge*, iii. pp. 249-55. Inference is a deeper thinking process from judgment to judgment, which only occasionally and partially emerges in the linguistic process from proposition to proposition. We may now then reassert two points about inference against Bradley's logic: the first, that it is a process from similar to similar, and not a process of identification, because two different things are not at all the same thing; the second, that it is the mental process from judgment to judgment rather than the linguistic process from proposition to proposition, because, besides the judgments expressed in propositions, it requires judgments which are not always expressed, and are sometimes even unconscious.

Our third point is, that as a process of judgments inference is a process from one belief in being to another, and not an ideal construction, because a judgment does not always require ideas, but is always a belief about things, existing or not. This point is challenged by all the many ideal theories of judgment already quoted. If, for example, judgment were an analysis of an aggregate idea as Wundt supposes, it would certainly be true with him to conclude that "as judgment is an *immediate*, inference is a *mediate*, reference of the members of an aggregate of ideas to one another." But really a judgment is a belief that something, existing, or thinkable, or nameable, or what not, is (or is not) determined; and inference is a process from one to another of such beliefs in being. Hence the fallacy of those who, like Bosanquet, or like Paulsen in his *Einleitung in die Philosophie*, represent the realistic theory of inference as if it meant that knowledge starts from ideas and then infers that ideas are copies of things, and who then object, rightly enough, that we could not in that case compare the copy with the original, but only be able to infer from idea to idea. But there is another realism which holds that inference is a process neither from ideas to ideas, nor from ideas to things, but from beliefs to beliefs, from judgments about things in the premisses to judgments about similar things in the conclusion. Logical inference never goes through the impossible process of premising nothing but ideas, and concluding that ideas are copies of things. Moreover, as we have shown, our primary judgments of sense are beliefs founded on sensations without requiring ideas, and are beliefs, not merely that something is determined, but that it is determined as existing; and, accordingly, our primary inferences from these sensory judgments of

existence are inferences that other things beyond sense are similarly determined as existing. First press your lips together and then press a pen between them: you will not be conscious of perceiving any ideas: you will be conscious first of perceiving one existing lip exerting pressure reciprocally with the other existing lip; then, on putting the pen between your lips, of perceiving each lip similarly exerting pressure, but not with the other; and consequently of inferring that each existing lip is exerting pressure reciprocally with another existing body, the pen. Inference then, though it is accompanied by ideas, is not an ideal construction, nor a process from idea to idea, nor a process from idea to thing, but a process from direct to indirect beliefs in things, and sometimes in existing things. Logic cannot, it is true, decide what these things are, nor what the senses know about them, without appealing to metaphysics and psychology. But, as the science of inference, it can make sure that inference, on the one hand, starts from sensory judgments about sensible things and logically proceeds to inferential judgments about similar things beyond sense, and, on the other hand, cannot logically go beyond the similar. These are the limits within which logical inference works, because its nature essentially consists in proceeding from one judgment to another about similar things, existing or not.

Finally, though sensory judgment is always true of its sensible object, inferential judgments are not always true, but are true so far as they are logically inferred, however indirectly, from sense; and knowledge consists of sense, memory after sense, and logical inference from sense, which, we must remember, is not merely the outer sense of our five senses, but also the inner sense of ourselves as conscious thinking persons. We come then, finally, to the old question—What is truth? It will be said that Kant has proved that real truth, in the sense of the "agreement of knowledge with the object," is unattainable, because we could compare knowledge with the object only by knowing both. Sigwart, indeed, adopting Kant's argument, concludes that we must be satisfied with consistency among the thoughts which presuppose an existent; this, too, is the reason why he thinks that induction is reduction, on the theory that we can show the necessary consequence of the given particular, but that truth of fact is unattainable. But Kant's criticism and Sigwart's corollary only derive plausibility from a false definition of truth. Truth is not the agreement of knowledge with an object beyond itself, and therefore *ex hypothesi* unknowable, but the agreement of our judgments with the objects of our knowledge. A judgment is true, whenever it is a belief that a thing is determined as it is known to be by sense, or by memory after sense, or by inference from sense, however indirect the inference may be, and even when in the form of inference of non-existence it extends consequentially from primary to secondary judgments. Thus the judgments "this sensible pressure exists," "that sensible pressure existed," "other similar pressures exist," "a conceivable centaur does not exist but is a figment," are all equally true, because they are in accordance with one or other of these kinds of knowledge. Consequently, as knowledge is attainable by sense, memory, and reason, truth is also attainable, because, though we cannot test what we know by something else, we can test what we judge by what we know. Not that all inference is knowledge, but it is sometimes. The aim of logic in general is to find the laws of all inference, which, so far as it obeys those laws, is always consistent, but is true or false according to its data as well as its consistency; and the aim of the special logic of knowledge is to find the laws of direct and indirect inferences from sense, because, as sense produces sensory

judgments which are always true of the sensible things actually perceived, inference from sense produces inferential judgments which, so far as they are consequent on sensory judgments, are always true of things similar to sensible things, by the very consistency of inference, or, as we say, by parity of reasoning. We return then to the old view of Aristotle's *Analytics* that logic analyses inference as a means to knowledge, and to the old definition of logic, *Logica est ars ratiocinandi, ut discernatur verum a falso*.

In conclusion, the logic of the last quarter of the 19th century may be said to be animated by a spirit of inquiry, marred by a love of paradox and a corresponding hatred of tradition. But we have found, on the whole, that logical tradition rises superior to logical innovation. There are two old logics which still remain indispensable, Aristotle's *Organon* and Bacon's *Novum Organum*. If, and only if, the study of deductive logic begins with Aristotle, and the study of inductive logic with Aristotle and Bacon, it will be profitable to add the works of the following recent German and English authors:—

Logroño, an inland province of northern Spain. With an area of 1945 square miles, it is divided into nine administrative districts and 184 parishes. The population was 181,465 in 1887, and 186,223 in 1897, when the birth-rate was 4·10 per cent., the death-rate 3·78 per cent., and illegitimacy 2·49 per cent. A railway line along the right bank of the Ebro connects the province with Saragossa, and from Miranda there is railway communication with Madrid, Bilbao, and France. Public educa-

tion is in a somewhat unsatisfactory condition, except in the larger towns. The industries and commerce grew considerably in importance during the last twenty years of the 19th century. Wine is the principal export, much as it has been reduced in consequence of the French imports of Spanish wine falling off, since 1892, by about 75 per cent. Great efforts have been made to keep a hold upon French and English markets with light red and white Rioja wines. No less than 128,000 acres are covered with vines, and 21,000 with olive groves. About 72,000 acres are devoted to wheat, 88,877 acres to barley, rye, oats, maize, and 4000 to pod fruit. The mines, almost without exception, are unproductive, but many of them (chiefly iron) could be worked profitably if the means of communication were improved.

Logroño, the capital of the above province, stands on the right bank of the Ebro, and had a population in 1897 of 19,475. The squares and public promenades have fine trees and are fringed with handsome modern houses and new buildings, contrasting with the older and narrow streets. The bull-ring holds 11,000 spectators. The see of Calahorra was transferred to Logroño in 1890.

Lohardaga, or RANCHI, a district of British India, in the Chota Nagpur division of Bengal. Area, 7140 square miles; population (1881), 1,058,169; (1891), 1,128,885, showing an increase of 7 per cent.; average density, 155 persons per square mile. In 1901 the population was 1,188,562, showing a further increase of 5 per cent. The land revenue and rates are Rs.1,02,442; number of police, 419; number of boys at school (1896-97), 18,132, being 21·9 per cent. of the male population of school-going age; registered death-rate (1897), 46·48 per thousand, this high mortality being due to drought and high prices of grain, which also seriously affected the attendance at school. In addition to relief works, the Government sanctioned a bounty on the importation of grain. The administrative headquarters are at Rauchi (20,306), where there is a lac factory, employing 60 hands, with an out-turn valued at Rs.25,000. There is a small military cantonment at Doranda. The German Evangelical Lutheran mission maintains several schools and a printing-press. The S.P.G. mission is also active. Tea cultivation has been introduced, but does not flourish. In 1897 there were 21 gardens, with 2438 acres under tea, employing 1132 persons, and producing an out-turn of nearly one million pounds. There is no railway in the district, though surveys have been made to connect with the Bengal-Nagpur line. In January 1900 some of the aboriginal tribe of Mundas rose and committed several murders, chiefly of native Christians and policemen; but the rising was promptly suppressed by military force.

Loharu, a native state of India, within the Punjab, situated in the south-east corner of the province, between Hissar district and Rajputana. Area, 226 square miles; population (1881), 13,754; (1891), 20,139; (1901), 15,233; average density, 67 persons per square mile; estimated gross revenue, Rs.66,077; military force, 94 men. The chief, whose title is nawab, is a Mahommedan, of Afghan descent. The nawab Amir-ud-din Ahmad Khan, K.C.I.E., who is a member of the Viceroy's Legislative Council, is also administrator of the state of Maler Kotla. The town of LOHARU is situated in 28° 24' N. and 75° 52' E.; population, 2038.

Loire, a river of France, rising in the department of Ardèche, and flowing north, north-west, and west to the Bay of Biscay, which it enters below Nantes. The total area drained is 207,060 square miles. The river is navigable only in a very limited sense, and, except in the two last sections of its course, by small boats only.

Below the confluence of the Maine facilities for navigation are increased, and the channel is capable of improvement. The disabilities do not apply to the Loire Maritime, as the section below Nantes is called. Great improvements have been effected by dredging and dyking operations, extending over several series of years between 1859 and 1892, resulting in the deepening of the channel, 82 yards wide, to about 15 feet. The most important work, however, was the construction of the MARITIME CANAL OF THE LOIRE. This work, decided on in 1879, was begun in 1881, and on 1st September 1892 the canal was opened for traffic, the undertaking having been successfully completed at a cost of about £1,000,000. The canal begins at Martinière, 1·2 mile below Nantes, and extends to Paimbœuf. At each end is a lock, 180 yards long by 19·6 yards wide. The canal has a total length of 9½ miles, width at surface 24½ yards, depth 19½ feet, capable of being increased to 24 feet. Since the opening of the canal, large ships can ascend to Nantes. Navigation is interrupted by ice on the average ten days in the year. The Loire is classed as flottable from Vorey (Haute Loire) to Noirie (Loire), 35 miles, and as navigable from Noirie to the sea, 513 miles; but in the upper course, for about 96 miles, there is neither flottage nor navigation.

Loire, a department in Central France, traversed by the mountains of Forez and of Lyonnais, and watered by the Loire, running through the middle of the department from south to north, and on its south-eastern boundary by the Rhône.

Area, 1853 square miles, divided among 30 cantons and 332 communes. The population, 603,384 in 1886, had increased to 644,532 in 1901. Births in 1899, 14,592, of which 771 were illegitimate; deaths, 12,955. The chief towns are St Étienne, with 146,671 inhabitants in 1901, Montbrison (7520), Roanne (34,568), Rive-de-Gier (16,087), and St Chamond (15,469). In 1896 there were 1130 primary schools, with 95,000 pupils, and 3 per cent. of the population were illiterate. The land under cultivation in 1896 amounted to over 1,028,000 acres; but the plough-land occupied only 573,000 acres, and the vineyards 44,480 acres. The wheat crop in 1899 produced the value of £582,000; rye, £400,000. Loire is one of the departments distinguished for the production of potatoes, yielding in 1899 a value of £520,000, and for natural pastures and grass lands, in which in 1899 the department returned the value of £880,000. Its vineyards produced the value of £216,000 in 1899. The live stock in 1899 included 14,800 horses, 158,810 cattle, 86,510 sheep, 63,360 pigs, and 47,890 goats. The coal basin of the Loire covers over 54,000 acres, divided among 28 companies. Its production in 1898 exceeded 3,850,000 metric tons, of the value of £2,200,000. During that year the industry in metals yielded 23,000 metric tons of cast-iron, 314,000 tons of iron, and 74,000 tons of steel, of a total value altogether of £2,200,000. St Étienne, St Chamond, and Rive-de-Gier are the centres of the mining and metallurgy. The manufacture of ribbons at St Étienne and its environs is carried on on a large scale, giving a yearly return of not less than 6 millions sterling. The weaving of muslins employs many hands in the zone of the Loire. According to the amount of horse-power it engages, Loire ranks as the third department in France. Its annual revenue is estimated at £14,000,000.

Loire, Haute, a department of Central France, traversed by the mountains of Velay (Mont Mézenc), and containing the upper waters of the Loire.

Area, 1931 square miles. From 320,063 in 1886 the population decreased to 306,671 in 1901. Births in 1899, 7561, of which 244 were illegitimate; deaths, 6672; marriages, 2317. In 1896 there were 987 schools, with 50,000 pupils, and not more than 3 per cent. of the population were illiterate. The land under cultivation was in 1896 estimated at 1,027,900 acres, but of this about 494,000 acres were covered with grass and forest, the plough-land occupying only 526,000 acres and the vineyards 17,300 acres. Wheat yielded in 1899 only £184,000; but the rye crop of the same year exceeded £693,000, while barley returned more than £159,000. Potatoes in 1899 produced the value of £357,000, and the natural pastures £1,180,000. The live stock is also relatively considerable, including (1899) 14,810 horses, 186,740 cattle, 306,750 sheep, 81,140 pigs, and 10,860 goats. The milk of the department yields a revenue of over £700,000 per annum. Haute-Loire possesses coal-pits, from which in 1898 it extracted 224,000 metric tons. It has also various metalliferous deposits, such as copper and lead,

but the industry in metals is not correspondingly extensive. The manufacture of lace occupies a number of hands. Le Puy, the capital, had 20,570 inhabitants in 1901.

Loire-Inférieure, a department of the west of France, at the mouth of the Loire.

Area, 2695 square miles. The population increased from 643,884 in 1886 to 656,998 in 1901. Births in 1899, 13,771, of which 649 were illegitimate; deaths, 11,638; marriages, 4848. The schools numbered in 1896, 789, with 89,000 pupils, and the illiterate formed 5 per cent. of the population. The land under cultivation amounted to 1,575,272 acres, of which 961,274 acres are plough-land, 308,890 acres natural pastures and grass lands, and 69,291 acres vineyards. Wheat, oats, and buckwheat are the only cereals largely cultivated. Their total produce in 1899 reached the value of £1,910,000. The vines reached the value of £1,582,000; mangold-wurzel, £224,000; natural pastures, £1,080,000. Hemp, yielding in 1899 a value of £24,000, and linen £15,500, supply the raw material to considerable industries. Apples, besides, gave a revenue of £240,000. The live stock includes 47,850 horses, 319,240 cattle, 91,700 sheep, and 113,500 pigs. The value of milk products in 1899 was £1,040,000. Loire-Inférieure in 1898 produced 20,000 metric tons of coal, 15,000 tons of peat, 10,530 tons of iron, and 48,000 tons of sea-salt, of a value altogether of £40,000. Metallurgy is in an advanced state around Nantes and St Nazaire, in the making of machines and ship engineering. In 1898 it produced 55,000 metric tons of cast-iron, 9500 tons of iron, and 49,000 tons of steel, to the value altogether, inclusive of industries in other metals, of £760,000. Industries connected with alimentation are in a thriving state along the course of the Loire, as is spinning in the interior. Distillation produces little more than 33,000 gallons a year. Nantes, the capital, had 128,349 inhabitants in 1901.

Loiret, a department of Central France, watered by the Loire, the Loing, and the Loiret.

Area, 2630 square miles. The population, 374,875 in 1886, only numbered 363,812 in 1901. Births in 1899, 7204, of which 606 were illegitimate; deaths, 6943; marriages, 2557. With 724 schools in 1896, attended by 53,000 pupils, 3 per cent. of the population were illiterate. The area under cultivation in 1896 amounted to 1,571,646 acres; 1,116,956 acres arable, 252,050 acres under wood, and only 49,422 acres under vines. The wheat crop was in 1899 estimated at £1,204,000; oats, £780,000; rye, £180,000; meslin, £112,000; barley, £128,000. The vintage of 1899 was valued at £212,000; mangold-wurzel at £144,000; natural pastures at £104,000. In 1899 the yield of beetroot was valued at £88,000, the department thus standing in 1899 the eleventh in France in this respect. In 1899 the live stock included 44,340 horses, 142,590 cattle, 320,790 sheep, and 37,750 pigs. Poor in minerals, Loiret has no extensive industry in metals. Much more important are its distilleries, sugar-refineries, and textile industries, more particularly hosiery. Orleans, the capital, in 1901 had 67,539 inhabitants.

Loir-et-Cher, a department of Central France, watered by the Loire, the Loir, and the Cher.

Area, 2479 square miles. The population decreased from 279,214 in 1886 to 274,836 in 1901. Births in 1899, 5334, of which 358 were illegitimate; deaths, 5229; marriages, 2121. There were in 1896, 658 primary schools, with 41,000 pupils, and 5 per cent. of the population were illiterate. The area under cultivation in 1896 comprised 1,462,916 acres, of which 916,790 were plough-land and 93,903 acres vineyards. In 1899 the produce of wheat was valued at £970,000; rye, £112,000; barley, £72,000; oats, £580,000; vines, £680,000. The green crop and grass lands give but a moderate return, as do also colza, rape, oil-poppy, hemp, flax, &c. The live stock included (1899) 37,770 horses, 91,050 cattle, 234,190 sheep, 47,580 pigs, and 20,900 goats. Mining and metallurgy are not advanced. Distillation hardly produces more than a thousand hectolitres. Blois, the capital (23,793), has important hosiery manufactures.

Lolos, the name given by the Chinese to a large tribe of aborigines who inhabit the greater part of southern Szechuen. Under this heading we give a short account of the various non-Chinese races scattered over south-western China.

Exclusive of Tibetans, there are three principal ethnological varieties: the Miaotze of Kweichow, the Lolos of Szechuen, the Shans of Yunnan. The Miaotze or Miautze were described in the earlier volumes (xv. 223) of this Encyclopædia (ninth edition), and need not further be referred to, save to say that they still maintain a semi-independence in their mountain homes, but appear to be a decaying race, gradually giving way before the more vigorous Chinese. The Lolos are a more

numerous and more important race. Their home is in the mountainous country called Taliang shan, which lies between the Yangtse river on the east and the Kien ch'ang valley on the west, in south Szechuen, but they are to be found in scattered communities as far south as the Burmese frontier, and west to the Mekong. The origin of the Lolos is not known, but there seems no reason to doubt that they were, like the Miaotze, one of the aboriginal tribes of China, driven southwards by the advancing flood of Chinese. The name is said to be a Chinese corruption of Lulu, the name of a former chieftain of a tribe who called themselves Nersu. They possess a written language which, like the Chinese, is monosyllabic and probably ideographic, and the characters employed bear a certain resemblance to Chinese. No literature, however, worthy of the name is known to exist, and the art of reading and writing is confined to a few. Politically they are divided into tribes, each under the government of a hereditary chieftain. The community consists of three classes, the "black-bones" or nobles, the "whitebones" or plebeians, and the *watze* or slaves. The last are mostly Chinese who have been captured in forays, or the descendants of such captives. Within the confines of Lolo-land proper, which extends to some 11,000 square miles, the Chinese Government exercises no jurisdiction. The people are independent and even aggressive, making frequent raids on their unarmed Chinese neighbours. They cultivate wheat, barley, and millet, but little rice. They have some knowledge of metals, making their own tools and weapons. Women are said to be held in respect, and may become chief of the tribe. They do not intermarry with Chinese. The Shans, the third race mentioned, are to be found all over the province of Yunnan and in the borderland between China and Burma. Shan is the Burmese name by which these tribes are known, and it has been generally adopted by Europeans, but they call themselves Tai, Punong, &c. The Chinese designate them usually Pai or Pa-yi. They are the descendants of a once powerful nation known in Chinese history as Yueh chang. They were masters at one time of a large part of what are now the provinces of Kwangsi and Yunnan, and were expelled only during the Yuan dynasty (1260-1368). The Examination Hall at Kweilin is said to be built on the ruins of an old Shan palace. Politically the Shan tribes, where not under the direct control of Chinese magistrates, are organized under their own chiefs, who are recognized by the Chinese Government and endowed with official rank and title. In Burmese such native chiefs are termed "Tsaubwa." Besides the three races just described, there are to be found in western Szechuen other native tribes who are variously termed by the Chinese Mantze, Sifan, and Kutsung. All these are in language, dress, and physique akin to the Tibetans, and may be regarded as offshoots of that race. They do not, as a rule, mix with the Chinese, but form semi-independent communities under tribal chiefs of their own choosing, whose authority is recognized by the Chinese officials.

See E. C. BABER. *Royal Geog. Society Sup. Papers*, vol. i. London, 1882.—F. S. A. BOURNE. *Blue Book, China*, No. 1. 1888.—A. HOSIE. *Three Years in Western China*. London, 1897. (G. J.)

Lombardy, a territorial division of northern Italy, embracing the middle portion of the valley of the Po, viz., the region contained between that river and the Swiss frontier, the lakes, and the Alps. It includes the provinces of Bergamo, Brescia, Como, Cremona, Mantua, Milan, Pavia, and Sondrio, and has an area of 9386 square miles, and a population of 3,680,615 (1881), and 4,278,188 (1901). Its principal crops are maize, wheat, rice, flax, hemp, wine, chestnuts, and potatoes. The only metals mined are zinc and iron. Lombardy is one of the busiest industrial regions in Italy. In parts of the region the peasantry suffer much from pellagra. The principal towns are Milan, Brescia, Bergamo, Pavia, Cremona, Como, Mantua, Lodi, and Monza. Pavia is the seat of a university. On the shores of the Alpine lakes and in the Alpine valleys there are a number of summer resorts, such as Tresco Balneario, Sondrio, Bormio, Varese, Gardone, Salò, and San Pellegrino. For the history see MILAN, MANTUA, and ITALY.

Lombok, by the natives called Sassak, one of the Lesser Sunda islands, in the East Indian Archipelago, east of Java, between 8° 12' and 9° 1' S. and 115° 46' and 116° 40' E., with an area of 3136 square miles. Since the war of 1894 the island has been placed under the direct government of the Dutch, the people being, how-

ever, left in undisturbed exercise of their own laws, religions, customs, and institutions. Lombok is now a division of the residency of Bali and Lombok, and since 1898 has been divided into West, Middle, and East Lombok. Its chief towns are Mataram, Praya, and Sisi. On the west coast the harbour of Ampanam is the most frequented, though, on account of heavy breakers, it is often difficult of approach. The island is traversed by two mountain chains. The northern chain is of volcanic formation, and contains the peak of Lombok, 11,810 feet high, one of the highest volcanoes in the Archipelago. It is surrounded by a plateau (with lower summits, and a magnificent lake, Segara Anak) 8200 feet high. The southern chain is only a little over 3000 feet high. Between the two chains is a broad valley or terrace with a range of low volcanic hills. The small rivers serve only for irrigation and the growing of rice. The mountains are covered with forest. The plains grow rice of superior quality; also, for export, coffee, indigo, maize, and sugar, katyang (native beans), cotton, and tobacco. The Balinese and Sassaks profess respectively Hinduism and Islamism, and their conflicts resulted in the war referred to below. The Sassaks are estimated at 320,000; the Balinese at 50,000; the Europeans (1897) at 39; the Chinese at 305; the Arabs at 172. The residency of Bali and Lombok has an area of 4063 square miles, and population (1896) of 1,044,757.

For geography and statistics see VAN ECK, "Schets van het Eiland Lombok," in *Tijdschrift Bat. Gen.* xxii.—JACOBS, *Eenigen Tijd onder de Baliërs*, 1883.—BIJVANCK, in *De Gids*, 1894-95.—NEEB and ASBECK BRUSSE. *Naar Lombok*, 1898. (C. M. K.)

History.—In July 1894 a Dutch expedition landed at Ampanam, and advanced towards Mataram, the capital of the Balinese sultan, who had defied Dutch authority and refused to send the usual delegation to Batavia. The objects of that expedition were twofold, to punish Mataram and to redress the grievances of the Sassaks, the aborigines of Lombok, whom the Balinese held in cruel subjection. The first Dutch expedition met with various reverses, and ultimately the invaders were forced back upon Ampanam, with the loss of several guns, and 9 officers and 90 men killed, 17 officers and 255 men wounded. The Dutch at once despatched a much stronger expedition, which landed at Ampanam in September. Mataram was bombarded by the fleet which had transported the troops, and these stormed the Sultan's stronghold, and Tjakra Negara, another chieftain's citadel, both after a desperate resistance. The old sultan of Mataram was captured, and he and other Balinese chiefs were exiled to different parts of the Malay Archipelago, whilst the sultan's heir fell at the hands of his warriors. Thus ended the Balinese domination of Lombok, and the island was placed under direct Dutch-Indian control, an assistant resident being appointed, who resides with a staff and a small garrison at Ampanam. Lombok is now administered from Bali by the Dutch resident on that island. The Sassaks, who are Mahomedans and distinct in many other respects from the Balinese Hindus, who vanquished but could not convert them, had their native rulers restored to them. They are far more numerous than the Balinese invaders, and disturbances between them and the Lombok Balinese frequently occur.

For recent history consult Wallace's *Malay Archipelago*, in whose famous "Dividing Line" Lombok plays an important part; Zollinger's *Travels* (in Dutch), published by the Dutch-Indian Government; Guillemard's *Cruise of the Marchesa* (2nd volume), and Captain W. Cool's *Lombok Expedition*, a narrative of the events sketched above, and published in 1896, in Dutch and English (Amsterdam and London). Wallace stayed some time at Ampanam, and gives many curious details, also a description of Mataram. Cool's book also contains many particulars about the folklore and dual religions of Lombok, which, with the adjacent Bali, forms the last stronghold of Hinduism east of Java. (H. T.)

Lombroso, Cesare (1836—), Italian criminologist, was born in November 1836 at Venice. After making himself known by his medical and anthropological studies, he was in 1862 appointed professor at Pavia, then director of the lunatic asylum at Pesaro, and finally professor at Turin. His works include *L'Uomo delinquente* (1876), *La Pella-gra in Italia* (1880), *Lezioni di medicina legale* (1886), *L'Uomo di genio* (1888), translated into English, and, in collaboration with G. Ferrero, *La Donna delinquente* (1893), also translated. Lombroso, like Bovio, Ferri, and Colajanni, well-known Italian criminologists, has been strongly influenced by Auguste Comte, and owes to him an exaggerated tendency to refer all mental facts to biological causes. In spite of this, however, and a serious want of accuracy and discrimination in handling evidence, his work has made an epoch in criminology; for he has surpassed all his predecessors by the wide scope and systematic character of his researches, and by the practical conclusions he draws from them. Their net theoretical result is that the criminal population exhibits a higher percentage of physical, nervous, and mental anomalies than non-criminals; and that these anomalies are due partly to degeneration, partly to atavism. The criminal is a special type of the human race, standing midway between the lunatic and the savage. This doctrine of a "criminal type" has been gravely criticized, but is admitted by all to contain a substratum of truth. The practical reform to which it points is a classification of offenders, so that the born criminal may receive a different kind of punishment from the offender who is tempted into crime by circumstances. Lombroso's biological principles are much less successful in his work on Genius, which he explains as a morbid, degenerative con-

dition, presenting analogies to insanity, and not altogether alien to crime.

Lomond, Loch, the largest of Scottish lakes, is situated in the counties of Stirling and Dumbarton. It is 20½ miles long in a straight line, and its greatest width is a mile, the area about 27 square miles, and the greatest depth 105 fathoms. It contains 30 islands, the largest of which is Inchmurrin, a deer park belonging to the duke of Montrose. The level of the loch is 23 feet above sea; it forms part of the route of one of two projected Forth and Clyde ship canals. The fish are sea-trout, lake-trout, pike, and perch. Part of the shore is skirted by the West Highland railway, opened in 1894, which has stations at Tarbet and Ardlui on the loch. There is a graceful waterfall at Inversnaid, which is also the point of arrival and departure for the Trossachs coaches. The country surrounding Inversnaid teems with Rob Roy memories. The ascent of Ben Lomond is made from Rowardennan. (See also TROSSACHS.)

Łomża (*Łomża* in Polish), a government of Russian Poland, to the north-east of Warsaw. Its population in 1897 was 585,781, of whom 279,279 were women, and 69,834 lived in towns. Out of a population of 626,582 on 1st January 1895 (including 15,940 military and 30,978 temporary inhabitants), there were 505,016 Catholics, 111,526 Jews, 6270 Protestants, and 3770 Orthodox Greeks. The industries are limited to a few breweries and potteries. The province is divided into seven districts, of which the chief towns are: Łomża, capital of the province (26,075), Kolno (4941), Maków (7232), Mazowiec (4931), Ostrolenka (8679), Ostrów (11,264), and Szczuczyn (5725).

L O N D O N.

LONDON, the capital of England and of the British Empire, is situated on both banks of the river Thames, about 50 miles from its mouth, St Paul's Cathedral being 51° 30' 48" N. and 0° 5' 48" W. The name "London," strictly speaking, belongs only to the City and liberties, and up to the end of the 18th century the distinction was always made between London and Westminster and Southwark, although a larger London included in the "Bills of Mortality" was also officially acknowledged. By Act of Parliament in 1888 the administrative county of London was formed, so that since that date it is legally correct to describe all places included in the county as parts of London. The

Area. area of the administrative county (including the City—673 acres) consists of 74,839 acres. This area includes 31,652 acres taken from the geographical county of Middlesex, 23,123 acres from Surrey, and 20,064 acres from Kent. No portion of Essex is included in the county. As the City of London is of greater antiquity than the county of Middlesex, it really never formed a part of Middlesex. The boundary divisions of the administrative county of London are: on the north—Hampstead, St Pancras (including portion of Highgate), Islington, Stoke Newington, and Hackney; on the east—Bow, Bromley, and Poplar; on the south-east—Greenwich, Charlton, Woolwich, and Plumstead; on the south—Eltham, Lee, Lewisham, Camberwell, Lambeth, Streatham, Tooting, Wandsworth, and Putney; on the west—Fulham, Hammersmith, Kensington, and Paddington. The registration county, the area of the School Board, and the metropolitan poor-law area are the same as the administrative county. The Central Criminal Court district contains 269,148 acres. Greater London (con-

sisting of the Metropolitan Police and City Police districts) contains 443,420 acres. The Metropolitan Police district contains the county of London, the whole of the county of Middlesex, and parts of the counties of Surrey, Kent, Essex, and Hertfordshire. The limits of the postal district are regulated by the Postmaster-General.

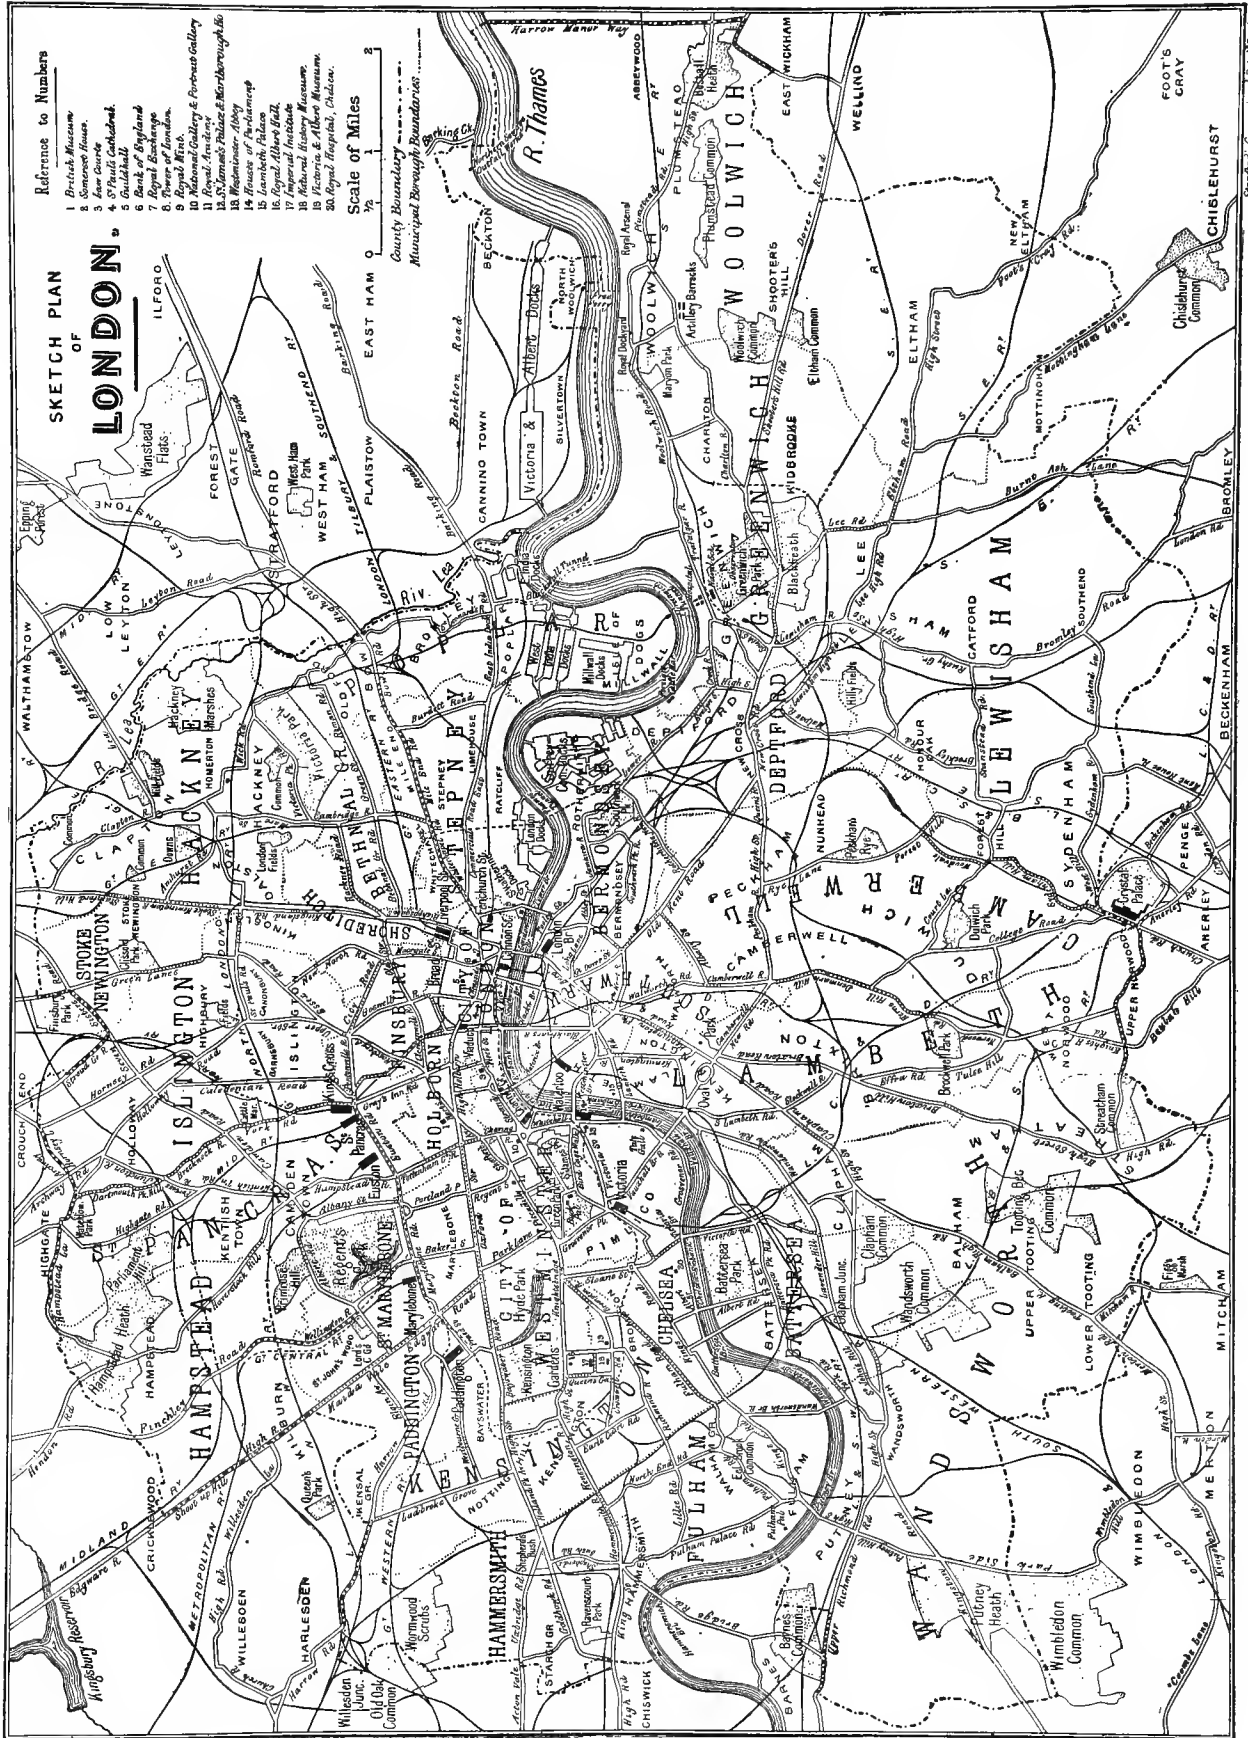

London is divided for parliamentary purposes into thirty parliamentary boroughs. Those on the north of the Thames are—Bethnal Green, Chelsea, City, Finsbury, Fulham, Hackney, Hammersmith, Hampstead, Islington, Kensington, part of Hornsey division of Middlesex, Paddington, St George's Hanover Square, St Marylebone, St Pancras, Shoreditch, Strand, Tower Hamlets, Westminster. Those on the south of the Thames are Battersea and Clapham, Camberwell, Deptford, Greenwich, Lambeth, Lewisham, Newington, Southwark part of north-eastern division of Wimbledon district of Surrey, Wandsworth, Woolwich.

Parliamentary boroughs.

The table on the following page gives the population of the parliamentary boroughs for the decennial periods 1881, 1891, and 1901, and the number of houses in 1901, divided between inhabited, uninhabited, and in course of building.

In accordance with the provisions of the London Government Act of 1899, vestries disappeared, and were replaced by borough councils. The first election of borough councils took place on 9th November 1900.

There are twenty-eight metropolitan boroughs in the administrative county of London, including the City of Westminster, but excluding the City of London. The new boroughs, although to a great extent the same as the parliamentary boroughs, are somewhat differently bounded.

SKETCH PLAN OF THE ADMINISTRATIVE COUNTY OF LONDON, SHOWING THE METROPOLITAN BOROUGH.

Year.	Letters Delivered.	Letters Registered.	Telegrams.	Persons Employed.		Total.
				Males.	Females.	
1896-1897	555,200,000	4,999,428	26,645,407	29,688	5018	34,701
1897-1898	590,900,000	4,789,067	27,419,241	30,842	5293	36,135
1898-1899	617,700,000	5,174,092	28,468,242	31,891	5652	37,543
1899-1900	632,600,000	5,555,544	29,971,884	32,185	5956	38,141
1900-1901	664,300,000	5,921,288	29,355,784	33,875	6299	40,174

Up to the year 1901 the National Telephone Company was practically the sole owner of telephone exchange communication in London, although the Post Office owned all the trunk lines connecting the various telephone areas of the company, and also worked a few exchanges outside London. The Select Committee on Telephones, appointed in 1898, reported the same year that "general immediate and effective" competition by either the Government or local authority was necessary. The result of this was that the Post Office was entrusted with the work, and most of the Post Office exchanges are now in working order. The area of the competitive telephone service is about 630 square miles, extending to Romford, Enfield, Harrow, &c. on the north, and to Epsom, Reigate, and Dartford on the south. The service is divided under three headings: A, exclusive lines; B, party lines; C, public call office. The charge under A is for (1) unlimited user and (2) limited user. In the first class £17 per annum for one line and £14 extra for each additional line; in the second class the charge is £4 or £5 per annum, with a charge of 1d. or 2d. a message. Under B the charge is £2 or £3 per subscriber, with the same charge per message as in A. In C the charge is 2d. per message to subscribers on any exchange.

The total area in London under crops and grass in 1899 was 12,548 acres, and in 1900, 12,054 acres. It was divided as follows:—

Year.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Small Fruit.	Fallow.
1899	629	2456	148	8922	350	43
1900	481	2201	142	8775	351	104

The following figures show the live stock for the same years:—

Year.	Horses. ¹	Cattle.	Cows and Heifers.	Sheep.	Pigs.
1899	805	5866	5467	5846	2607
1900	806	5409	...	2462	2518

In 1870 the value of the land not used for buildings was set down at £118,836, while in 1894 it was estimated at £67,560.

The population of the area now included in the administrative county of London in 1831 was 1,655,099, but in 1901 the number had risen to 4,536,541. This increase has taken place chiefly in the outer districts, as the central districts have decreased in population. The population of the City in 1801 was 128,129; in 1831 it was 122,491; in 1851, 127,819. Since 1851 the number has uniformly decreased, and in 1901 it stood at 26,923. The decrease in the other central districts between 1851 and 1896 was as follows:—

Holborn	47,000 to 31,000
St Giles's	54,000 ,, 38,000
St James's	36,000 ,, 23,000
St Martin's	25,000 ,, 13,000
St Marylebone	153,000 ,, 141,000
Strand	44,000 ,, 24,000
Westminster	65,000 ,, 53,000

¹ By horses is meant horses used solely for agricultural purposes, and unbroken horses.

The increase of population in the outer districts between 1851 and 1896 was as follows:—

Battersea	11,000 to 165,000
Camberwell	55,000 ,, 253,000
Fulham	12,000 ,, 114,000
Greenwich	67,000 ,, 176,000
Hackney	54,000 ,, 213,000
Hammersmith	18,000 ,, 104,000
Hampstead	12,000 ,, 75,000
Islington	95,000 ,, 337,000
Kensington	44,000 ,, 170,000
Lambeth	139,000 ,, 295,000
Lewisham	16,000 ,, 270,000

These figures are those given by Sir John Wolfe Barry in November 1898, before the creation of the metropolitan boroughs (*Journal Society of Arts*, vol. xlvii. p. 10).

Births, Deaths, and Marriages.

The registration of births, deaths, and marriages is under the direction of the Registrar-General, but is directly carried out by the several boards of guardians, and the figures relating to this subject are to be found in the annual report of the Registrar-General.

The following table shows the marriage-, birth-, and death-rate per thousand of the population, with the percentage of illegitimate births, for a series of years:—

	1870-79.	1880.	1880-89.	1890.	1889-98.	1899.
Marriage-rate	19·2	18·1	17·6	17·6	17·6	18·4
Birth-rate	35·4	35·3	33·7	30·7	30·7	29·3
Death-rate	22·8	21·7	20·5	21·0	19·3	19·4
Percentage of illegitimacy	3·9	3·9	3·9	3·8	3·7	3·6

The following table gives the number of marriages, births, and deaths, with the number of illegitimate births, in 1880, 1890, 1899:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	34,144	133,310	81,832	2627	2546
1890	36,752	128,161	87,689	2492	2410
1899	41,876	133,134	88,063	2495	2254

Emigration and Immigration.

	1891.	1899.	1900.	1901.
Emigrants embarking at the Port of London	29,140	23,329	26,236	25,010
Alien immigrants arriving at the Port of London	17,476	26,840	33,039	29,729

"Emigrants" comprise passengers leaving London for places outside Europe.

Nationality of Aliens arriving at the Port of London.

	1900.	1901.
Russians and Poles	17,939	15,958
Norwegians, Swedes, and Danes	1,226	1,143
Germans	2,818	3,593
Dutch	1,617	1,685
French	468	549
Austrians and Hungarians	2,174	1,724
Italians	241	143
Other nationalities	4,110	2,275
	30,593	27,070
Add seamen	2,441	2,655
	33,034	29,725

The number of foreigners in London in 1891 was 95,063, and in 1901, 135,377.

The total expenditure in London for the relief of the poor, exclusive of the operation of the poor fund, was, according to the return of the Local Government Board, in 1899-1900, £3,446,132. There are thirty-one boards of guardians, five boards of managers of school districts, and two boards of managers of sick asylum districts. The parishes and unions which favour outdoor relief, and which have a majority of paupers in receipt of

outdoor relief on their books, are Poplar, Lewisham, Woolwich, Camberwell, Wandsworth and Clapham, St Olave's, Hackney, and Islington. The following have more indoor than outdoor paupers: Whitechapel, St George's-in-the-East, Stepney, Strand, Kensington, Chelsea, and St George's, Hanover Square.

The following table gives the number of paupers:—

	1897-98.	1898-99.	1899-1900.
Indoor paupers	53,089	59,259	59,359
Outdoor paupers	39,039	38,907	38,987
Vagrants	1,322	1,302	1,297
Pauper lunatics	13,784	14,387	14,887
Paupers of all classes	118,647	120,265	120,912
Admission to casual wards	181,728	183,138	174,362
Average number on Friday nights—			
Men	815	825	789
Women	210	216	199
Children	20	23	21
Total	1045	1064	1009

The amount spent in London in 1899-1900 on in-maintenance was £920,936; outdoor relief, £223,624; maintenance of lunatics in asylums and licensed houses, £414,963; salaries and superannuation allowances, £767,262; loans repaid and interest, £524,099. The remainder is described as "other expenses of, or immediately connected with, relief." The Metropolitan Asylums Board is a central authority created by the Metropolitan Poor Act of 1867, to provide accommodation for the infectious sick and the harmless insane. There are seventy-three managers, fifty-five of whom are elected by the boards of guardians, and eighteen are nominated by the Local Government Board.

The County Council, as the central health authority of London, is entrusted by the Legislature with important powers of action in default of local sanitary authorities. The death-rate per thousand living *Health.* in 1900 was 18·6, as against 19·3 in 1899. Of the sanitary districts showing a rate below this there were:—Battersea (17·8), Camberwell (17·0), Chelsea (18·5), Fulham (17·7), Greenwich (18·1), Hackney (16·7), Hammersmith (17·1), Hampstead (11·4), Islington (17·1), Kensington (15·8), Lambeth (18·2), Lee (13·4), Lewisham (14·1), Paddington (16·3), Plumstead (16·0), St George's, Hanover Square (14·5), St James's (15·8), St Martin's-in-the-Fields (17·7), Stoke Newington (13·2), and Wandsworth (14·2). The sanitary districts having the highest death-rates were:—Bermondsey (23·6), Bethnal Green (21·8), Clerkenwell (22·0), Holborn (25·7), Limehouse (26·4), City of London (21·6), Newington (22·4), Poplar (22·6), Rotherhithe (22·9), St George's-in-the-East (24·4), St George's, Southwark (27·3), St Luke's (28·6), St Olave's (21·6), St Saviour's, Southwark (25·6), Shoreditch (22·0), Strand (22·4), and Woolwich (22·1).

The death-rate per thousand living from 1881 to 1900 was as follows:—

1881	21·3	1886	20·6	1891	21·0	1896	18·1
1882	21·5	1887	20·3	1892	20·3	1897	17·7
1883	20·8	1888	19·3	1893	21·0	1898	18·2
1884	20·9	1889	18·4	1894	17·4	1899	19·3
1885	20·4	1890	21·4	1895	19·5	1900	18·6

The following table gives the total births and deaths, and the deaths from zymotic diseases, 1881 to 1900:—

Deaths from Zymotic Diseases and from all Causes, 1881-1900.

Year.	Total Births.	Total Deaths.	Deaths of Infants under One Year.	Deaths from Principal Zymotic Diseases.								Percentage of Deaths from Principal Zymotic Diseases.

Various attempts to improve the thoroughfares of London have been made since the formation of Regent Street in 1813-20, but they have proved to be quite inadequate to relieve the constantly increasing congestion. The greatest improvement was the construction of the Thames Embankment, which at once restored the river to its proper position as the prominent feature of the town that originally grew up by its shores. The Victoria Embankment, on the north bank, from Blackfriars to Westminster, and the Albert Embankment on the south bank, from Westminster Bridge to Vauxhall, were both opened in 1870. The Chelsea Embankment, on the north bank, from Battersea Bridge to Chelsea Bridge, was finished in 1874. The dates of the chief improvements in the thoroughfares of London during the latter half of the 19th century are as follows:—1854, Cannon Street; 1864, Southwark Street; 1870, Holborn Viaduct; 1871, Hamilton Place, Queen Victoria Street; 1876, Northumberland Avenue; 1882, Tooley Street; 1883, Hyde Park Corner; 1884, Eastcheap; 1886, Shaftesbury Avenue; 1887, Charing Cross Road; 1890-92, Rosebery Avenue. The great improvement of a new road running north to south from Holborn to the Strand is under construction. The chief streets are all too narrow, especially the Strand and Fleet Street. These are being widened, but there seems to be little hope of any adequate relief of the congestion until a drastic system of readjustment is carried out. One of the

chief causes of obstruction is due to the crossing of main thoroughfares. Sir John Wolfe Barry, when chairman of the Council of the Society of Arts, proposed in his opening address to the Society in 1899 a series of crossings of east and west, and north and south traffic, by means of bridges over and tunnels under the streets at six of the important places of intersection:—1, Hyde Park Corner; 2, Piccadilly Circus; 3, Ludgate Circus; 4, Oxford Street and Tottenham Court Road; 5, Wellington Street and Strand; 6, Southwark Bridge and Upper Thames Street.

BRIDGES ACROSS THE THAMES.

Property of the Corporation of the City of London.

- Tower Bridge (opened 1894).
- London Bridge (opened 1831).
- Southwark Bridge (opened 1819).
- Blackfriars Bridge (opened 1869).

Property of the London County Council.

- Waterloo Bridge (opened 1817).
- Charing Cross footbridge (opened 1878); the railway bridge is the property of the South-Eastern Railway Company.
- Westminster Bridge (opened 1860-62).
- Lambeth Bridge (completed 1862).
- Vauxhall Bridge (opened 1816; new bridge in course of erection).
- Victoria or Chelsea Bridge (opened 1858).
- Albert Bridge (completed 1873).
- Battersea Bridge (opened 1890).
- Wandsworth Bridge (opened 1880).
- Putney Bridge (opened 1886).
- Hammersmith Bridge (opened 1887).

The bridges referred to as the property of the Metropolitan Board of Works became so under the terms of the Metropolis Toll Bridge Act, 1877 (40 and 41 Vict. c. 99), and on the passing of the Local Government Act, 1888, they were transferred to the London County Council, which expends a sum of £10,000 per annum on their maintenance. Besides bridges, there are several tunnels under the Thames.

Thames Tunnel (2 miles below London Bridge) was commenced in 1825, and opened for public traffic in 1843. It was sold in 1865 to the East London Railway for £200,000. The original cost was over £600,000.

Tower Subway, a tunnel from Tower Hill to Tooley Street, was constructed in 1869-70 at a cost of £16,000. The tunnel is reached at each end by a shaft about 60 feet deep.

Blackwall Tunnel, connecting Poplar with Greenwich, was constructed by the London County Council, in accordance with an Act passed in 1887, at a total cost of £869,476. The tunnel was opened by the prince of Wales, 22nd May 1897. In addition to the cost of making the tunnel, the Council has spent a sum of £350,000 in the acquisition of property, £70,000 in erecting dwellings for persons of the working classes who have been displaced in the carrying out of the scheme, and £64,000 in making the approach roads from Lower Woolwich road to the tunnel. With other minor works and incidental expenses the Blackwall Tunnel Scheme necessitated an expenditure approximating to £1,383,502. The annual cost of maintenance is about £6300.

Greenwich Tunnel (from Greenwich to Millwall). An Act was passed in 1897 authorizing the County Council to construct a subway for the use of pedestrians only, to connect the Isle of Dogs and Greenwich. It was opened in 1902.

Rotherhithe Tunnel (between Rotherhithe and Ratcliff), authorized under local act 1900, was in 1902 under construction.

Woolwich free ferry was constructed under the powers of the Metropolitan Board of Works (Various Powers) Act, 1885, and was opened by the earl of Rosebery on 23rd March 1889. The total cost incurred by the Council in forming and improving the ferry (including the formation of approach roads, river walls, piers, acquisition of land, &c.) and building the ferry-boats was £182,775, and the annual working expenses are £18,405. The number of passengers using the ferry in 1900 was 5,319,070, and the number of vehicles 437,961.

The chief means of communication from place to place in London are supplied by omnibuses, tramways, railways, and steamboats, the statistics of which are given in the following tables. The average number of omnibuses running during the first half of 1900 belonging to the London General Omnibus Company was 1372, and 480 to the Road Car Company. The number of passengers carried by the London General

Omnibus Company in 1900 was 199,575,529; by the Road Car Company in the same year, 64,948,339.

Omnibuses.

	Receipts.	Expenditure.	Gross Profits.
London General Omnibus Company, 1899	£1,205,644	£1,116,357	£89,287
London General Omnibus Company, 1900	1,245,174	1,157,918	87,256
London Road Car Company, 1899	381,784	337,053	44,731
London Road Car Company, 1900	383,575	351,364	32,211

Tramways.—When the County Council was formed, there were thirteen tramway companies in existence. The Council set to work to secure possession of these undertakings in virtue of its powers under the Tramways Act of 1870, and will ultimately be in possession of all the tramways of London. There are twelve companies having running powers in the county, with a total length of line—115 miles within, and 33 miles outside the county. The County Council owns 48 miles of line, at present worked by the North Metropolitan Tramways Company, the standard gauge being 4 feet 8½ inches.

The gross receipts and expenditure for the year 1898-99 were as follows:—

Gross receipts	£1,376,148
Total working expenditure	1,086,386
Gross profits	£289,762
Number of passengers in the same year	294,002,749
Number of miles run by cars	28,699,059
Number of horses	14,114
Number of cars	1,489
Number of omnibuses	111

Electrical tramways and light railways (1901) operated or authorized:—

Steamboats.—From various causes, pier dues being the chief, the steamboat service on the Thames has greatly declined. It has been proposed that the service should be undertaken by the London County Council. The London, Westminster, and Vauxhall Steamboat Company established in 1840 a service of seven steamboats between London Bridge and Vauxhall. This company was bought up by the Citizen and Iron Steamboat Companies in 1865. The City Steamboat Company, established in 1848, began with eight boats, and by 1865 had increased their fleet to seventeen, running from London Bridge to Chelsea. This company was taken over by the London Steamboat Company in 1875. The sinking of the *Princess Alice* in 1878 was a serious blow to the London Steamboat

Company, which collapsed, and was succeeded by the River Thames Steamboat Navigation Company, which went into liquidation in 1887. The fleet of thirty-three vessels was bought by a syndicate and sold to the Victoria Steamboat Association. In recent years the service has been run by the Thames Steamboat Company with a fleet of 36 boats, but early in 1902 the Company announced that their service of boats would be discontinued. The County Council in 1902 promoted a Bill in Parliament to empower them to run a service of boats on the Thames, but the Bill was thrown out.

The inadequacy of the dock accommodation for modern ships has long been realized, and London is losing its share of the carrying trade of the country largely from this cause. In 1901 a Royal Commission was appointed "to inquire into the present administration of the Port of London and the water approaches thereto; the inadequacy of the accommodation provided for vessels, and the loading and unloading thereof; the system of charge for such accommodation, and the arrangements for warehousing dutiable goods; and to report whether any change or improvement in regard to any of these matters is necessary for the promotion of trade in the public interest."

The chief authorities concerned in the government of the Port of London are:—

1. *Thames Conservancy*.—For conservancy purposes, regulation of navigation, removal of obstruction, dredging, &c. The area of its jurisdiction differs in limits for various purposes.
2. *City Corporation*.—Port sanitary purposes from Teddington Lock seawards.
3. *Trinity House*.—Pilotage, lighting, and buoying from London Bridge seawards.
4. *The Watermen's and Lightermen's Company*.—The licensing authority for watermen and lightermen.

Besides these authorities, the London County Council, the Board of Trade, the Admiralty, the Metropolitan and City Police, police of riparian boroughs, Kent and Essex Fisheries Commissioners, all the dock companies, and others, play some part in the government and public services of the port.

The Thames Conservancy receipts and expenditure for the year 1900 were as follows:—

Receipts, Lower Navigation	£104,388
" Upper Navigation	33,640
Expenditure, Lower Navigation	88,806
" Upper Navigation	38,535

The dock companies are partly consolidated, and the revenues and expenditure for 1899 were:—

Total revenue	£2,311,302
" expenditure	1,644,999
Balance carried forward towards interest and dividends	£666,303

The Rivers Committee of the London County Council reported in January 1901 on the need of improvement

in the Port of London, and recommended (a) the deepening and improvement of the Thames on the lines indicated in the report of the Lower Thames Navigation Commission and in the evidence given before the Royal Commission by Sir Alexander Binnie (then the Council's engineer, who estimated the cost at less than £2,000,000 spread over several years); (b) the improvement of the docks, their equipment and approaches. The committee further recommended that all administrative control should be absolutely left to a statutory authority to be called "The Port of London Committee," of not more than thirty members, of whom ten should be from the Council, two from the City Corporation, ten should be representatives of the shipowners and merchants, and the other members to be appointed by Government departments.

The wholesale supply of food to London is chiefly carried on through the authorized markets. There are a few retail markets, but these are little more than the informal markets established by costermongers in the public streets. These were formerly more common than at present.

The principal markets are under the administration of the Corporation of the City of London. They are—

- London Central Markets at Smithfield (meat, poultry, provisions, fruit, vegetables, flowers, and fish).
- Leadenhall Market (meat and poultry).
- Billingsgate Market (fish).
- Smithfield Hay Market (hay).
- Metropolitan Cattle Market at Islington (cattle).
- Deptford Cattle Market (foreign cattle).
- Coal Market (coal).

The total debt on the City markets on 31st December 1898 was as follows:—

London Central Markets	£1,758,500
Leadenhall Market	247,800
Billingsgate Market	274,500
Metropolitan Cattle Market	396,600
Deptford Cattle Market	21,000
	£2,698,400

There are also three markets either directly or indirectly controlled by local authorities. They are—

Whitechapel Hay Market, under control of trustees; Borough Market, under control of trustees, including the overseers of St. Saviour's, Southwark; Woolwich Market, under control of Woolwich Local Board, now the metropolitan borough of Woolwich.

There are also a few markets in the hands of private owners, namely, Covent Garden and Spitalfields Markets (fruit, vegetables, and flowers); Cumberland Market (hay); and Shadwell Market (fish).

There are also informal and street markets held in various parts of London.

London has always been famous for its squares and open spaces, but with the immense increase in the area it has been difficult to keep pace with the needs of the enormous population, and large districts are deficient in open spaces. In the county of London the area of commons consists of 2162 acres, of parks and gardens 1654 acres, and of royal parks 1249 acres. The royal parks are St James's Park and Green Park; Hyde Park and Kensington Gardens; and Regent's Park. Among the chief open spaces under the control of the London County Council may be mentioned Battersea Park (opened 1858); Blackheath (transferred 1871); Bostal Heath, &c. (purchased 1877-94); Brockwell Park (purchased 1890); Clapham Common (rights purchased 1877); Clissold Park (purchased 1889); Dulwich Park (presented to the Metropolitan Board of Works by Dulwich College); Finsbury Park (1857); Hampstead Heath, Golder's Hill, and Parliament Hill (1871-99); Lee, open space (1902); Peckham Rye Park, Plumstead Common (1878); Southwark Park (1864); Streatham Common, Tooting Bec, and Tooting Graveney Common (1873-75); Victoria Park (1842); Wandsworth Common (1871); Waterlow Park, Highgate (1892); Wormwood Scrubs (1879).

Besides these parks, commons, &c., there are the gardens of the Thames embankments, playgrounds, disused churchyards, &c. The London County Council are anxious to preserve wild birds in London, and in January 1900 they obtained from the then Home Secretary (Sir M. W. Ridley, afterwards Viscount Ridley) an order for wild birds' protection (county of London), which was given in pursuance of powers conferred upon the Home Secretary by the Wild Birds' Protection Acts, 1880-96. The order protects birds and their eggs in the various London pastures under penalties.

The total acreage of London cemeteries is 608¾.

The most important change made in the heart of London has been caused by the destruction of a large district in order to form the new road north of the Strand to Holborn. The destruction of Holywell Street has made the widening of the Strand a possibility, and the north side of that thoroughfare from the courts of law to Wellington Street has been entirely altered. The chief of the newly-constructed buildings have been hotels and theatres. No feature of London life has undergone so radical change of late years as that connected with

the improvement of hotels and the supply of palatial buildings such as the Cecil, the Carlton, and the Hotel Russell in Russell Square. The rebuilding of Her Majesty's Theatre and the construction of the Carlton Hotel to form one architectural whole has made a great change in the Haymarket and Pall Mall. In these alterations the well-known opera colonnade has disappeared. The increase of comfort in the newest London theatres has been very marked, and Her Majesty's Theatre stands at the head of the theatres of London on account of the improved arrangements for the accommodation of the public. Another marked change in the appearance of the streets has been caused by the building of flats in all parts of London.

Twenty-five boroughs have adopted the Baths and Wash-houses Acts. In seventeen of these boroughs the Acts are in force throughout the whole borough, and in eight the Acts are only in **Public baths.** force in parts of the borough.

The number of bathers and washers at the public baths and wash-houses during 1897-98 reached a total of 5,090,990; of these, 4,463,109 were bathers, and the remaining 627,881 were women who used the wash-houses. The number of bathers was made up as follows:—

Bathers in private baths—		
1st class	650,338	
2nd class	1,697,620	
		2,347,958
Bathers in swimming baths—		
1st class	705,456	
2nd class	1,409,695	
		2,115,151
		4,463,109

The expenditure on water forms a considerable item in the accounts of baths and wash-houses authorities. The total cost of water supplied at twenty-six establishments which were open during the year 1897-98, and which were supplied wholly by one or other of the eight companies, was £12,522. In no case in London is an establishment carried on so as to produce a surplus, though there are many instances where the actual deficit is less than the charge in respect of the repayment and interest on debt. Prior to the rebuilding of the Marylebone Baths in 1895, there was a surplus for several years, which was paid over to the relief of the rates. There was no actual charge on the rates for the year 1897-98 in respect of either St James's, Westminster, or St George's-in-the-East establishments, but there were deficits to the extent of £660 and £184 respectively, which were met by corresponding decreases in balances.

The following is a summary of the receipts and expenditure for 1897-98 of the thirty-four authorities administering the Baths and Wash-houses Acts in London:—

<i>Expenditure.</i>	
Interest and repayment of loans	£62,563
Buildings—Repairs, rents, rates, and taxes, &c.	16,881
Working Expenses—Coals, gas, water, salaries, &c.	78,927
Total expenditure	£158,371

<i>Receipts in Aid.</i>	
Tickets sold—Baths, £55,991; Laundries, £14,027	£70,018
Various—Soap, soda, towels, &c.	5,298
Total receipts in aid of expenditure	£75,316
Resulting charge falling on rates	£83,060

The public and domestic lighting of London has been

long in the hands of the Gas Companies, but since 1886 a large number of electric light companies have come into existence. At the end of 1901, 15 local authorities and 16 companies possessed statutory powers to supply electricity. The following table gives

some statistics of the electricity supplies of the various local authorities and companies which were in working order in 1900-01; that is to say, in the case of the borough councils up to 31st March 1901 and the companies till 31st December 1900:—

	Number of Customers.	Supply commenced.	Number of Units sold.			Amount of Loans outstanding.

Electric lighting is also carried out by companies and local authorities in districts immediately around the county of London, as Acton, Barking, Ealing, Harrow, West Ham, Wimbledon, &c.

Mr A. H. Preece's paper on "The Electricity Supply of London" read before the Institution of Civil Engineers in 1898 (*Proceedings*, vol. cxxxiv. pp. 121-205) contains a large amount of information up to the date of its publication, but the years 1900 and 1901 are

specially memorable for the large increase in the supply of electrical power.

Gas.—Gas is supplied mainly by three companies—the Gas Light and Coke Company, the South Metropolitan Company, and the Commercial Company. Some other companies supply the outer districts of the county. Gas has to be supplied at sixteen-candle illuminating power, and is officially tested by the Chemists' department of the County Council.

Gas Companies, 1899.

(c) South of Thames.

The chief courts for the trial of criminal cases are, in London, the Central Criminal Court (which takes the place of the Assizes in the provinces) and the Court of Quarter Sessions. There are twelve sessions of the central criminal court in the year, while the sittings of the court of quarter sessions are

held thirty-six times in the year. The inferior criminal courts are the courts of summary jurisdiction or police courts.

The following table shows the number of crimes known to the police, 1893-99, and the number of persons apprehended for indictable and non-indictable offences:—

Year.	Average Daily Strength of Police.	Crime known to Police.	Indictable Offences.			Non-indictable Offences.			Persons apprehended.						Total Number apprehended.

The total number of *elementary* day schools on the 31st August 1900 was 975, of which 484 were board and 491

Education. voluntary, made up of 342 National Church of England, 16 Wesleyan, 101 Roman Catholic, 32 British and others. The average number of attendances was 616,918.

The expenditure of the School Board for London, for the year ended 25th March 1900, was £3,387,666 (an increase on the previous year of £182,554), leaving a balance for the year of £312,182. The rate levied was 13-37d. for the entire year.

The Board of Education was formed under the provisions of the Board of Education Act, 1899. On the 6th of April 1900 the Board issued a minute, which was approved by Parliament, enabling the Board to recognize a new class of public elementary schools termed "higher elementary schools."

The report of the Board of Education, 1900-01, deals with *secondary* education, which is divided under technical instruction and science and art instruction. The Board is authorized to inspect any school supplying secondary education and desiring to be so inspected.

Considerable changes have been made in the foundation schools of London. St Paul's School has been removed to Hammersmith, Charterhouse School to Godalming (Merchant Taylors' School taking its place at Charterhouse), King's College School to Wimbledon, Christ's Hospital to Horsham, and the City of London School to Victoria Embankment.

Examinations in technology have been conducted by the City and Guilds of London Institute for the Advancement of Technical Education for several years. In 1880 the number of subjects was 24; the number of centres of examination, 89; and the number of candidates, 816.

¹ Including Government contribution under the Agricultural Rates Act.

In 1899 the number of subjects had increased to 63; the number of centres to 397; and number of candidates to 14,004. The number of registered classes in 1899 was 1764, and of students in attendance, 34,176. The gross expenditure in 1899 was £33,720, of which £12,229 was expended on the Central Technical College; £9835 on the Technical College, Finsbury; £7272 on the Leather Trades School; and £1204 on administration. The net cost, after deducting students' fees, was £22,373.

The University of London was first incorporated by Royal Letters Patent, dated 28th November 1836. It had hitherto been an examining body for conferring degrees, but was reorganized in 1900 in accordance with statutes and regulations drawn up by the Royal Commission appointed under the University of London Act, 1898. It now undertakes teaching as well as examination, and is divided into the faculties of theology, arts, law, music, medicine, engineering, and economics and political science. The governing body consists of the senate (including chancellor, vice-chancellor, and chairman of convocation), and 54 appointed members. The University has been removed from Burlington Gardens to the Imperial Institute, South Kensington, the eastern wing and central portion of which have been transferred to the University. Accommodation for examinations in physics and chemistry will be found in the new buildings of the Royal College of Science.

Museums, &c.—The Victoria and Albert (late South Kensington) Museum, and Bethnal Green Branch Museum; the Museum of Practical Geology, Jermyn Street; the Geological Survey of the United Kingdom; and the committee of Solar Physics, are dealt with in the Report of the Board of Education, 1899-1900, in connexion with secondary education.

British Museum and Natural History Museum, South Kensington. The Parliamentary vote for 1901-02 was for the Bloomsbury establishment, £151,686; and for Natural History Museum, £62,121.

The Royal United Service Institution has been removed from Whitehall Yard to the Banqueting House, Whitehall.

Art.—National Gallery and Tate Gallery, Parliamentary vote, 1901-02, £24,808. The Tate Gallery or National Gallery of British Art, Millbank, was opened in 1897, and extended in 1899. Wallace Gallery, Hertford House, Manchester Square, was opened 1900; the Parliamentary vote, 1901-02, was £32,313. The National Portrait Gallery in St Martin's Place was opened in 1896; the Parliamentary vote, 1901-02, was £7760. Leighton House, 2 Holland Park Road, Melbury Road, Kensington, presented to the nation by Lord Leighton's sisters, contains 370 original drawings, paintings, and studies by Lord Leighton; open daily. Exhibitions of pictures are held at the Royal Academy, Burlington House, Piccadilly; the New Gallery, 121 Regent Street (established 1888); the Grafton Gallery, Grafton Street, built 1893; the Fine Art Society, 148 New Bond Street; the Art Gallery of the Corporation of London, Guildhall, established in 1885, &c., &c. There are also a large number of Art Societies which hold exhibitions.

Statues erected in London since 1832.

Anne (Queen), St Paul's Churchyard, after Bird by Boehm.
Boadicea, Victoria Embankment, Westminster.
Burns (Robert), Victoria Embankment Gardens.
Carlyle (Thomas), Chelsea Embankment Gardens.
Cromwell (Oliver), Old Palace Yard.

Forster (Rt. Hon. W. E.), M.P., Victoria Embankment Gardens.
Frere (Sir Bartle), Victoria Embankment Gardens.
Gordon (General), Trafalgar Square.
Strathnairn (Field-Marshal Lord), Knightsbridge.
Raikes (Robert), Victoria Embankment Gardens.
Tyndale (William), Victoria Embankment Gardens.
Victoria (Queen), Blackfriars Bridge.
Wellington (Duke of), Hyde Park Corner.
Wesley (John), graveyard of the City Road Chapel.

(For *London Fire Brigade*, see FIRE.)

GOVERNMENT AND ADMINISTRATION.

The revolution effected in London administration by the legislation of 1888 and 1899 is intelligible only in the light of the history of the local government of the district now known as the county of London before the year 1888. Until 1855 there can hardly be said to have been a system of local government for London outside the City (as to the City, see the earlier volumes of the *Encyclopædia Britannica*, 9th ed., xiv. 818). For a distance of many miles outside the City there was a belt of very thickly populated country, governed, as in the most rural and most sparsely populated districts, by the inhabitants of the parish in vestry assembled, except where the parishes had availed themselves of the provisions of Hobhouse's Act (1 and 2 Will. IV. c. 60), and had elected a select vestry. The vestry (whether open or select) had, however, no powers of what is known as town management. To meet the needs of particular localities, commissioners or trustees having powers of town management were from time to time created by local Acts. The chaos resulting from this piecemeal legislation is summarized in Sir B. Hall's speech on introducing the Metropolis Management Bill in 1855 (*Hansard*, vol. cxxxvii. pp. 705, 899). From his speech it appears that in 1855 the number of local Acts in force in the metropolis was 250, administered by not less than 300 different bodies; the number of persons serving on these bodies was computed at 10,448. These persons were either self-elected, or elected for life, or both, and therefore in no degree responsible to the ratepayers. In addition there were two bodies having jurisdiction over the whole metropolis except the City,—the one being the officers appointed under the Metropolitan Building Act of 1844, and the other the Metropolitan Commissioners of Sewers, appointed under the Commissioners of Sewers Act, 1848. Neither body was responsible to the ratepayers. To remedy this chaotic state of affairs, the Metropolis Management Act, 1855, was passed. Under that Act a vestry elected by the ratepayers of the parish was established for each parish in the metropolis outside the City. The vestries so elected for the twenty-two larger parishes were constituted the local authorities. The fifty-six smaller parishes were grouped together in fifteen districts, each under a district board, the members of which were elected by the vestries of the constituent parishes. Woolwich, which had previously become a local government district under a local board, was left untouched, and therefore not subject to the law applicable to the rest of the metropolis. A central body, styled the Metropolitan Board of Works, having jurisdiction over the whole metropolis (including the City) was also established, the members of which were elected by the Common Council of the City, the vestries and district boards, and the local

board of Woolwich. Further, the area of the metropolis for local government purposes was for the first time defined, the area adopted being the same as that included in the Commissioners of Sewers Act, 1848, which in its turn had been taken from the area of the weekly bills of mortality. To the Metropolitan Board of Works was assigned the duty of constructing and maintaining the main drainage of London, in which work they superseded the old Commissioners of Sewers; the Board was also given certain powers of supervision over the vestries and district boards, and by an Act of the same session was constituted the central authority for the administration of the Building Acts. The vestries and district boards became the authorities for sewerage (except so far as related to main drainage), and for paving, lighting, repairing, and maintaining streets and highways, and for the removal of nuisances, superseding the commissioners and trustees created by local Acts, the surveyors of highways, and (by an amending Act 19 and 20 Vict. c. 112) all existing vestries, whether open or select. The City of London remained as before a county of a city governed by an unreformed Corporation. Between 1855 and 1888 many additional powers and duties were conferred on the Metropolitan Board of Works and on the vestries and district boards. The constitution of the Board of Works, however, was open to objection on the ground that the system of election was indirect in the case of all its members and doubly indirect in the case of those elected by the district boards, and the sense of responsibility was proportionately weakened. Some of its acts were open to such suspicion that a Royal Commission was appointed to inquire into certain matters connected with the working of the Board.

An attempt was made in 1884 by Sir William Harcourt to constitute the metropolis a municipal borough under the government of a single council, to which it was proposed to transfer the existing powers of the Metropolitan Board of Works and of the vestries and district boards, and the administrative powers of justices. But it was not until 1888 that the next step in advance towards the solution of the problem of London local government was definitely taken. The Local Government Act of that year dealt with the area of the metropolis as if it were a separate county, both for administrative and for non-administrative purposes. For non-administrative purposes—quarter sessions, justices, militia, coroners, sheriffs, &c.—so much of the counties of Middlesex, Surrey, and Kent as lay within the metropolis (or in other words, the whole of London exclusive of the City) was constituted a county at large, with an organization corresponding to that of other counties in England, except so far as that organization is modified by the existence of the central criminal court, the metropolitan police, the metropolitan police courts and their magistrates, and a paid chairman of quarter sessions. The position of the City as a county of a city was left almost untouched, except that the right of appointing a sheriff for Middlesex was taken away. For administrative purposes the whole of the metropolis, including the City, was constituted an administrative county, having, as in other counties, a county council as the central administrative body, differing only from other county councils in that the number of councillors and the electoral divisions were fixed by the Act, and that the aldermen number not less than one-sixth, instead of one-third, of the councillors. The total number of councillors is 118, four members being elected for the City, and two for each of the other parliamentary boroughs and divisions in London. The City for administrative purposes was treated as quarter sessions boroughs with a population exceeding 10,000 were treated elsewhere in England, the powers of the council of a borough

Act of
1888.

of that class being either transferred or reserved to the Common Council. To the County Council, in addition to the administrative powers conferred on it as on the councils of other counties, there were transferred the extensive powers of town government previously vested in the Metropolitan Board of Works, including not only direct administrative functions, but also various powers of control over the action of the subordinate local authorities. Most of the powers so transferred were exercisable only outside the City, but some (for example, main drainage) extended to the area of the City. How great these powers were may be appreciated from the following summary of what the defunct Board had effected. It had "constructed a main drainage system at a cost of more than six millions and a half; embanked the Thames; freed most of the bridges from toll; constructed vast arteries of street communication; established and maintained a metropolitan fire brigade; provided and maintained 2603 acres of parks and open spaces free to the public for ever; exercised a controlling jurisdiction over the half-million buildings of London; cleared vast insanitary areas; and in many other ways discharged under more than 120 Acts of Parliament important municipal functions in London." The County Council thus not only obtained large powers of town government over the whole area of the administrative county with the exception of the City, but also powers and functions within the City which no other county council exercises in a borough lying within its administrative area. On the other hand, the Corporation of the City retained rights and powers which by ancient privilege or special legislation extended beyond the area of the City and applied to or affected the whole of London, such, for instance, as market rights and powers as to foreign cattle and as port sanitary authority. The area within which these powers were exercisable was not curtailed, and their exercise connects the City with the administrative county of London in a way in which no ordinary borough is connected with the administrative county in which it lies. In spite of these anomalies, the broad fact remains that under the Act of 1888 the inhabitants of the metropolis acquired for the first time a direct control over the most important matters of municipal work. But in another direction the Act was confessedly incomplete in dealing both with the county of London and with the other counties of England. It contemplated the establishment by some future Act of subsidiary district councils in London and elsewhere. This intention was carried into effect as respects all places outside London by the Local Government Act, 1894. But the framers of that Act were content, in respect of London, with abolishing the property qualification of vestrymen, extending the franchise to all parochial electors, and removing the right of the incumbents of parishes to be *ex officio* chairmen of vestries.

The larger and more wealthy parishes became discontented with the form of local government to which they remained subject. The evil associations which still cling to the terms "vestry" and "vestryman" perhaps deterred the persons best qualified from seeking seats on the governing body. Accordingly in 1897 Kensington and Westminster petitioned to be created boroughs by the grant of charters under the Municipal Corporations Acts. But these Acts are inapplicable to London, and to make them applicable special legislation would have been required. It was then decided that, in constituting new

Act of 1899.

local authorities in London, it would be advisable to follow the lines indicated by the report of the Commissioners appointed in 1893 to inquire into the conditions under which the amalgamation of the county and City could be effected, and that the

form of local government should be homogeneous throughout London outside the City, and that it would be inexpedient to have boroughs dotted about here and there in London, as would have been the result of the grant of charters under the Municipal Corporations Acts. The result of this decision is embodied in the London Government Act, 1899. This Act divided London into twenty-eight districts of very various sizes, ranging, at the date of the passing of the Act, in population between 336,764 and 50,377, in area between 9106 acres and 409 acres, in rateable value between £4,977,802 and £320,089. Each of these districts is called a metropolitan borough—a terminology which may cause difficulties and misconceptions in the future, the term "borough" having hitherto been (in reference to local government) a term of art, meaning a borough under the Municipal Corporations Acts. One of the most notable features of the Act is the revival of the old city and liberties of Westminster, embracing the parishes of St Margaret and St John, St George Hanover Square, St James's, St Martin-in-the-Fields, the district of the Strand Board of Works, and the close of the Collegiate Church of Westminster. This large area, with a rateable value exceeding that of the City, is formed into a single metropolitan borough. Each borough is governed by a council consisting of a mayor, aldermen, and councillors, the number of aldermen being one-sixth of that of the councillors. The qualifications and mode of election of the mayor and aldermen are assimilated to those of the chairman and aldermen of county councils. The franchise is left unaltered, and in other respects the law relating to the vestries is applied to the new councils (except that women are disqualified for holding office either as mayors, aldermen, or councillors). Woolwich is brought into line with the other districts in London. The accounts of the new councils are made subject to Government audit. To the new councils are transferred all the powers of the old vestries and district boards, of the commissioners of public libraries and baths and wash-houses, and of burial boards, and certain minor powers of the London County Council. A few additional powers and duties, including a power to promote and oppose Bills in Parliament, are given to and imposed on the new councils. Power is also given to the Local Government Board to transfer in the future, by provisional orders, powers and duties from the County Council to the borough councils and from the borough councils to the County Council, but the consent of the County Council and of a majority of borough councils is necessary in every case. A similar power of transfer similarly exercisable is given with respect to the powers and duties of the County Council and the Common Council of the City.

The Act leaves the City practically untouched, but a local Act passed in 1897 abolished the old Commissioners of Sewers for the City and vested their powers and duties in the Corporation of the City, acting through the Common Council. The Common Council thus became the sanitary authority for the City. The coal duties leviable by the Corporation were abolished in 1889 by 52 and 53 Vict. c. 17.

Much has been done to simplify and systematize the local government of London, but it remains anomalous, and perhaps from the nature of the case it must be anomalous. As the supreme authority there is a County Council which exercises, in addition to the powers of an ordinary county council, various powers of town government exercisable elsewhere by the councils of boroughs; in the centre is the City, an area governed by an unreformed Corporation exercising the powers exercisable elsewhere by the councils of quarter sessions boroughs of over 10,000 inhabitants, but also having some powers which extend far beyond the City area; the rest of the county is divided into boroughs, which are not boroughs in the ordinary acceptation of the word, and whose constitution resembles in some respects municipal boroughs, in others county councils, and in others urban district councils.

Powers.—In distributing powers between the central and local authorities the principle observed has been to give all powers and duties which require uniformity of action throughout the whole of London to the County Council, and powers and duties that can be locally administered to the local authorities, uniformity in some cases being secured by giving the County Council power to regulate the administration by by-laws. Of late the tendency has perhaps been to give to the County Council powers which might with advantage have been given to the local authorities. However, the conference of representatives of the local authorities which was held in 1895-96 to discuss what powers might be transferred from the County Council to the local authorities, found but few, and these comparatively unimportant, which could be so transferred. The Act of 1899 carried into effect such of the recommendations of this conference as were approved by the County Council. The result is that the County Council is the authority to deal with the following matters:—main sewers, tramways, embankments and the prevention of floods, fire brigade, metropolitan commons, parks and open spaces (with a few exceptions), the naming and numbering of streets, the formation and width of new streets, the line of frontage in streets, the pollution of rivers (except the Thames and the Lea), the licensing of theatres (except those within the jurisdiction of the Lord Chamberlain), music halls and racecourses, technical instruction, the making of by-laws as to the rule and good government of London as to overhead wires, &c., *bridges, *locomotive traffic, *street improvements, *constant water supply, *infant life protection, *storage &c. of petroleum and explosives, *contagious diseases of animals, *coroners, *gas testing, *asylums, *reformatory and industrial schools, *shop hours, *weights and measures testing, *dangerous and neglected structures, *the housing of the working classes, *common lodging houses, *licensing of offensive trades and slaughter-houses. This list does not pretend to be complete. A useful summary of the powers of the County Council will be found in Appendices VII. and IX. of the report of the Unification Commission in 1894 (C. 7493 II.), and in the report of the conference of local authorities referred to above. The matters marked with an asterisk are in the City under the control of the Common Council. The Common Council of the City and the new metropolitan borough councils are the authorities for paving, lighting, cleansing, and watering streets, for making and maintaining the local sewers, for removing nuisances, for providing and maintaining public libraries, baths and wash-houses, and burial grounds, and for acting generally as the sanitary authorities; they can also exercise concurrently with the County Council some of the powers of that Council.

Expenditure.—The performance of such numerous and important functions involves heavy expenditure. The following table shows the sums expended by the various authorities on the municipal administration of London in 1898-99, and the manner in which such expenditure was met:—

Authority.	Expenditure.	Receipts in Aid from			Amounts Raised by Rates.
		Imperial Taxation.	Indirect Local Taxation.	Other Sources.	
County Council	£ 2,511,315	£ 130,895	£ 520,505	£ 341,648	£ 1,519,308
Metropolitan Asylums Board	603,686	<i>nil</i>	<i>nil</i>	1,810	635,450
Metropolitan Police (London proportion)	1,588,714	653,223	31,769	281,633	671,630
City Corporation	732,421	<i>nil</i>	153,365	503,054	125,914
Sanitary Authorities (including the Common Council of the City)	3,533,188	<i>nil</i>	7,451	554,386	2,881,191
Commissioners of Baths and Wash-houses and Public Libraries and Burial Authorities	206,463	<i>nil</i>	36,667	69,629	100,175
Total	9,175,787	748,118	749,757	1,752,160	5,833,663

(a) Of this sum £947,075 was defrayed out of the county rate.

Besides the annual expenditure, large sums have been borrowed to defray the cost of works of a permanent nature. The debt of London, like that of other municipalities, has considerably increased, and shows a tendency to go on increasing. Of the tables in the next column, the first shows the total amounts raised for various purposes by the Metropolitan Board of Works and the London County Council, and the second, the state of indebtedness of those authorities at the time when the powers of the former were transferred to the latter and at the close of the financial year 1898-99.

The net liabilities of the County Council, after deducting assets, on 31st March 1899 were £21,562,018; of this amount the sum of £2,131,576 represented remunerative expenditure. In 1899 the indebtedness of the Corporation of the City was £5,750,983; of the vestries and district boards, and of the local board of

Woolwich, and of burial boards and commissioners of baths and wash-houses and public libraries, £4,802,519.

Amounts Raised.

	Main Drainage.	Street Improvements and Embankments.	Bridges, Subways, &c.	Housing of Working Classes.	Parks and Open Spaces.	Fire Brigade.
Metropolitan Board of Works, 1856-88	£ 6,779,525	£ 15,363,374	£ 2,351,305	£ 1,549,176	£ 650,646	£ 487,606
London County Council, 1889-98	1,188,755	1,292,423	1,640,406	1,029,600	765,476	471,368
Total	7,968,280	16,655,797	3,991,711	2,578,776	1,416,122	958,974

State of Indebtedness.

Date	Total Amount raised.	Loans to Other Authorities outstanding.	Amount Applied to repay Debt.	Net Liability after deducting Assets.
31st Dec. 1888	£ 37,440,728	£ 8,723,986	£ 9,659,806	£ 16,972,469
31st Mar. 1899	51,617,488	16,760,480	10,784,750	21,562,018

In addition to the provisions already noticed, the London Government Act, 1899, simplifies administration in two respects. The duties of overseers in London have been performed by most diverse bodies. In some parishes overseers were appointed in the ordinary manner; in others the vestry was, by local Acts and by orders under the Local Government Act, 1894, appointed to act as, or empowered to appoint, overseers; in others local Acts constituted various statutory bodies to perform the functions of overseers, whilst in Chelsea the guardians acted as overseers. The Act of 1899 swept away all these distinctions, and constituted the new borough councils in every case the overseers for every parish within their respective boroughs, except that the town clerk of each borough performs the duties of overseers with respect to the registration of electors.¹ Again, with regard to rates, there were in all cases three different rates leviable

in each parish—the poor rate, the general rate, and the sewers rate—whilst in many parishes in addition there was a separate lighting rate. From the sewers rate and lighting rate, land, as opposed to buildings, was entitled to certain exemptions. Under the Act of 1899 all these rates are consolidated into a single rate, called the general rate, which is assessed, made, collected, and levied as the poor rate, but the interests of persons previously entitled to exemptions are safeguarded. Further, every precept sent by an authority in London for the purpose of obtaining money which has ultimately to be raised out of a rate within a borough is sent direct to the council of the borough instead of filtering through other authorities before reaching the overseers. The only exceptions to this rule are (1) precepts issued by the Local Government Board for raising the sums

to be contributed to the metropolitan common poor fund; and (2) precepts issued by poor-law authorities representing two or more poor-law unions: in both these cases the precept has of necessity to be first sent to the guardians. With the object of equalizing rates in different parts of London, the richer parts are required under various enactments to contribute towards the expenses of the administration of the poorer parts. By the Metropolitan Poor Act, 1867, the metropolitan common poor fund, to which each union in London contributes in proportion to

¹ Over 200 local Acts have been repealed by schemes made under the Act of 1899.

its rateable value, was established. Out of this fund certain expenses of guardians in connexion with the maintenance of indoor paupers and lunatics, the salaries of officers, the maintenance of children in poor-law schools, valuation, vaccination, registration, &c., are paid. The payments amounted in 1898-99 to £1,336,986. Under the Local Government Act, 1888, the County Council makes grants to boards of guardians, sanitary authorities, and overseers in London in respect of certain services. This grant is in lieu of the grants formerly made out of the Exchequer grant in aid of local rates, and amounted in 1898-99 to £566,738. Finally, in 1894, the fund called the Equalization Fund was established. This fund is raised by a rate of 6d. in the £ levied annually on the whole county of London, and redistributed amongst the sanitary authorities on the basis of population. It amounted in 1898-99 to £915,118. The amount of parish, union, and district expenses so paid out of rates levied on the whole of London (including a small grant by the Metropolitan Asylums Board) was in 1898-99 £2,822,735, equal to about 27·2 per cent. of the local expenditure raised by rates; and out of a total of £10,401,441 raised by rates, £7,363,829 was raised by rates levied over the whole county. But, in spite of these attempts at equalization, rates remain very unequal in London, and varied in 1899 between 5s. 3d. in St James's, Westminster, and 8s. 8d. in Rotherhithe.

SANITATION.

The original statutes relating to public health applied to London equally with the rest of England, but when in 1875 these statutes were consolidated and amended, London was expressly excluded from the scope of the new Act, and remained under the old law. The law applicable to London was consolidated and amended in 1891, and differs from that in force elsewhere mainly in three directions:—(1) The London County Council is a central sanitary authority, and as such deals with main drainage,

the housing of the working classes, infant life protection, contagious diseases of animals, common lodging-houses and shelters, and other matters where uniformity of administration is essential or desirable. (2) The County Council to a certain extent controls and supervises the work of the local sanitary authorities for the purpose of promoting uniformity and efficiency of administration. Uniformity of administration is promoted by means of the by-law-making power of the Council. The Council may make by-laws regulating the construction of local sewers, and the construction, cleansing, and repair of all pipes, drains, &c.; as to sanitary conveniences, cesspools, and ashpits; prescribing the times for the removal of faecal or offensive matter and refuse; regulating offensive businesses, slaughter-houses, and dairies; and for the prevention of nuisances not otherwise preventible by the local authorities. Efficiency of administration is promoted chiefly in two ways. The Council not only appoints a

medical officer of health for the whole county, but pays half the salaries of the medical officers of health and the sanitary inspectors of the local authorities. The Council may also act where local sanitary authorities¹ make default with respect to the removal of any nuisance, the institution of any proceedings, or the enforcement of any by-laws, and may make representations to the Local Government Board as to the failure of the local authorities to perform their duties. Further, if the Local Government Board are satisfied that a local sanitary authority has failed to perform its duties, the Board may direct the County Council to withhold the whole or any part of any payment due to the authority under the Equalization of Rates Act, 1894. (3) The Metropolitan Asylums Board, though originally established in 1867 as a purely poor-law authority for the relief of sick, insane, and infirm paupers in London, has since become a central hospital authority for infectious diseases, having power to receive into its hospitals persons, who are not paupers, suffering from fever, smallpox, or diphtheria. The Metropolitan Asylums Board and the County Council have also, for the purpose of the epidemic regulations, such powers and duties of a sanitary authority as may be assigned to them by those regulations.

For the purpose of the local administration of the sanitary laws London is divided into sanitary districts, each district being under the jurisdiction of a local sanitary authority having, subject to the above-mentioned limitations, much the same powers as sanitary authorities elsewhere in England. The City and the various metropolitan boroughs are the sanitary districts, and the Corporation (acting through the Common Council) and the metropolitan borough councils constitute the local sanitary authorities.

The system of main drainage inaugurated by the Commissioners of Sewers in 1849, and carried out by the Metropolitan Board of Works from 1856 to 1888, has since 1889 been maintained, completed, and improved by the London County Council. The most important improvement effected by the latter body has been the erection of pumping machinery and stations in low-lying localities to prevent flooding in times of storm. The London main sewers receive, besides the sewage from London, that from West Ham, Penge, Tottenham, and Wood Green, and from parts of Beckenham, Hornsey, Croydon, Willesden, East Ham, and Acton. The length of the main intercepting sewers in London now exceeds 87 miles; their construction has cost nearly eight million pounds. The systems on the north and south of the Thames are distinct. The sewage on the north side is dealt with at the Barking outfall works, that on the south side at Crossness. The sewage at these outfall works is treated with lime and proto-sulphate of iron. By means of this treatment the sewage is transformed into a clear innocuous effluent and sludge. The effluent is allowed to flow into the Thames, the sludge is taken fifty miles out to sea, a service on which six sludge ships are constantly employed; the sludge so carried amounted to 2,344,000 tons in 1898-99. The total amount of sewage treated exceeds 76,876,250,000 gallons a year, and the annual cost of the maintenance of the main drainage system (exclusive of any charge for the payment of interest or repayment of capital) approaches £200,000. The sanitary authorities are concerned only with the supervision of house drainage and the construction and maintenance of local sewers discharging sewage into the County Council's main sewers.

The London County Council have pursued (as did their predecessors the Metropolitan Board of Works) an active policy

¹ This power may not be exercised in the case of the City.

under the Artisans' Dwellings and Housing of the Working Classes Acts, having from 1856 to 1898 incurred a capital expenditure of £2,578,776 for the purpose. Under Part I. of the Act of 1890 (which consolidated the previous enactments) large insanitary areas may be cleared and accommodation provided for the labouring classes displaced; Part II. makes similar provisions with respect to smaller areas; Part III. enables accommodation to be provided for the working classes

irrespective of displacement. Schemes under Part I. are carried out by the County Council, schemes under Part II. by either the County Council or by the local sanitary authority, usually with a contribution from the Council to the local authority or *vice versa*, as the case may be. Part III. may be adopted either by the County Council or the local sanitary authority. The following table gives the details as to the principal schemes carried out or in course of being carried out:—

Improvement Schemes under the Artisans' and Labourers' Dwellings Improvement Acts and the Housing of the Working Classes Act in London.

Name of Scheme.	Commenced.	Estimated Net Cost.	Actual Net Expenditure to Date.	Persons displaced.	Persons for whom Accommodation is provided.
<i>By Metropolitan Board of Works:—</i>					
Whitechapel and Limehouse	1876	£ 54,400	£ 151,763	3,669	3,600

Totals	2,132,154	...	55,283	46,691

Note.—The above figures as to cost represent the net cost of clearing the land only, i.e., the cost of the land less its value for housing purposes.

(a) Site devoted to purposes of an open space.

(b) To be carried out at the expense of Lord Portman.

(c) The local authority concerned contributes one-half the net cost.

The County Council in 1899 passed a resolution in favour of providing dwellings under Part III. of the Act apart from the rehousing required in connexion with clearance and improvement schemes, provided that no charge was placed on the county rate thereby. Seven schemes under this part of the Act have already been, or are in the course of being carried out by the County Council. Under the Totterdown Fields scheme it is proposed to provide accommodation for 11,000 persons, and under the Millbank Estate scheme for 4434. It is estimated that the rents received will be sufficient to repay the interest on the capital expended, and the sinking fund charges.

The provisions of the Infectious Diseases (Notification and Prevention) Acts, which for London are embodied in

the Public Health (London) Act, 1891, are carried out by the local sanitary authorities, but the hospitals for the reception of infectious cases are provided and maintained by the Metropolitan Asylums Board. **Infectious diseases.** In the execution of this duty the Board has established eleven hospitals (including a convalescent hospital) with accommodation for 4500 patients, and two hospital ships and a convalescent hospital at Darenth for the treatment of 1500 smallpox cases. The admissions to the Board's hospitals in 1898 numbered 21,063. The Board also maintains an ambulance service for infectious diseases

throughout London; the mileage run of this service in 1898 was 214,677 miles. The Board's expenditure on the common charges account was, in 1898-99, £603,686, in addition to the sums contributed by the various boards of guardians in London for the maintenance of patients chargeable to their several unions. It is impossible to distinguish what proportion of the sum of £603,686 should be classified as sanitary expenditure and what as expenditure on poor relief.

The other duties of sanitary authorities, such as the removal of nuisances, scavenging, the cleansing of streets, and the like, are performed by the local sanitary authorities. The efficiency with which these bodies have performed their duties varies enormously. It is difficult, however, to discover any criterion by which to gauge their respective efficiency, especially as their accounts have hitherto not been made up on any uniform principle. But, speaking broadly, the tendency has distinctly been towards a better administration of the law. The number of sanitary inspectors appointed has steadily grown, and in 1898 reached 256, an increase of thirty as compared with the previous year.

The Thames Conservancy Board, originally constituted in 1857 and reconstituted in 1866, was further remodelled in 1894. The Board under the Act of 1894 (57 and 58 Vict. c. 187) now contains nominees or representatives of the Admiralty, the Board of Trade, the Trinity House, the Corporation of the City, the London County Council, the councils of the counties and chief boroughs through which the river flows, ship-owners, owners of barges, lighters, and tugs, dock-owners, wharfingers, and the metropolitan water companies. The Act of 1894 further enlarged the powers of the Board, chiefly by extending their control of pollution to the whole watershed of the river. Much has been done by the Board to purify the Thames by the detection and prohibition of sources of pollution. So far has the purification proceeded that a project has been initiated for the reintroduction of salmon into the river. The Lea has been similarly improved under the Lea Conservancy Board. The chief sources of impurity have been removed by the reception into the London sewers (under the Lea Purification Act, 1886, and the Wood Green Sewage Act, 1891) of the sewage from Tottenham and Wood Green.

WATER SUPPLY.

In spite of the reports of many commissions and committees recommending that the water supply of London should be improved and vested in a body representative of the consumers, and in spite of various attempts to carry such recommendations into effect, the eight metropolitan water companies still maintain their position, and the Thames and the Lea remain the chief sources of supply.¹

In the case of a provincial town the transfer of the water undertaking of a company to the corporation is a comparatively simple matter, even if the corporation is in consequence authorized to supply water to a small district outside their borough. In London the problem is complicated by the fact that of the area of 620 square miles within which the eight companies are authorized to supply water only 121 square miles are within the county of London, and of the 5,814,219 persons supplied by the companies in 1898 only some 4,526,500 resided in London. Consequently the efforts of the London County Council to purchase the undertakings of the companies have been opposed not only by the companies, but also by the councils of the surrounding counties, parts of which are within what is known as "Water London." These councils

demand that, in the event of the purchase by the London County Council of the companies' undertakings, not only the means of distribution within their respective areas should be made over to them, but also that a portion of the sources of supply should be allotted to them, so that they should not be dependent on the London County Council for their water supply. The London County Council is pledged, in the event of the Council purchasing the undertakings of the companies, to make such an apportionment. But the Royal Commission presided over by Lord Llandaff reported that "although severance of the works and sources of supply of the several companies, and the division thereof between the councils of the six counties within the limits of supply, are not actually impracticable, they would be very difficult and highly undesirable." Many attempts have also been made to solve the difficulty by constituting a body representative of the various authorities interested, but such attempts have met with but little favour. Lord Llandaff's Commission proposed the creation of a Water Trust as the only method by which the purchase of the water companies could be effected. The price to be paid to the companies constitutes another obstacle to purchase. The companies contend that they should be bought out on the same terms as have almost invariably been given to water companies in the provinces, that is to say, that the price to be paid should be settled by agreement, and failing agreement, by compulsory arbitration under the Lands Clauses Acts. The London County Council, on the other hand, contend that the price so fixed would be exorbitant, and that in assessing the value of the undertakings regard should be had to the prospective liability of the companies to provide new works and new sources of supply, and that no allowance should be made for compulsory sale. To the present sources of supply objection is taken both on the ground of the quality and of the quantity of the water derived from those sources. By the construction of subsidence reservoirs and filter-beds much has of late years been done to improve the quality of the London water, and the Commission presided over by Lord Balfour of Burleigh in 1893 reported that, though not blind to the fact that the provisions as to filtration and subsidence differed enormously in different companies, and in some were quite inadequate, they considered that the water as supplied to the consumer in London was of a very high standard of excellence and purity. And this opinion was endorsed by Lord Llandaff's Commission. Both these Commissions also came to the conclusion that if the present sources of supply were utilized to their utmost by the construction of large storage reservoirs, 420,000,000 gallons daily might be drawn from them, whilst leaving a sufficient supply of water for the navigation of the Thames and Lea. This would supply 35 gallons a head to 12,000,000 persons, and would suffice till 1941. Doubt has been thrown on the conclusions of the Balfour Commission as to the capacity of the present sources, but the Llandaff Commission accepted their conclusions. Both Commissions pronounced in favour of a scheme for the construction of large storage reservoirs in the Thames valley at an estimated cost of from £9,000,000 to £10,000,000. This scheme has already been begun to be carried out by three of the companies, the New River Company, the West Middlesex Company, and the Grand Junction Company, which are jointly constructing large storage reservoirs at Staines. The London County Council, on the other hand, is in favour of bringing the necessary additional supply from Wales, and it has for the past few years yearly introduced Bills authorizing the Council to acquire two large catchment areas in Wales, and to impound the head-waters of the Wye, the Towy, and the Usk. The part of the County Council's scheme which would give approximately the same amount of water as the Thames valley scheme is estimated to cost something over £10,000,000, but if the accumulated interest during the construction of the works and for pumping charges is taken into account, it would bring the cost up to over £15,000,000. This cost, in the opinion of Lord Llandaff's Commission, was prohibitive.

The system of constant supply has been extended almost universally throughout "Water London," but the droughts in the summers of 1895 and 1898 compelled the East London Company to suspend the supply of water between certain hours during several months in each of those years. As during the same period some of the other companies had a surplus of water beyond their own requirements, an Act was passed in 1899 (62 and 63 Vict. c. 7) providing for the interconnexion of the systems of the various companies, and for the supply of water from one company to another.

Parliament has lately imposed stringent restrictions on the raising of new capital by the companies. Since 1878 the increase of share capital has in no case been authorized; further capital, if required, has to be raised by the issue of debenture stock, the debenture stock has to be sold by public auction, and the premiums, if any, realized by the sale applied as capital money. Again, since 1886 a clause, known as the sinking fund clause, has been inserted in all Bills authorizing the creation of new capital. Under this clause a certain percentage on the new capital has annually to be paid by the company to the Chamberlain of the

¹ A Bill was introduced by the Government in 1902, in order to constitute a water board, and to transfer to the board the undertakings of the metropolitan water companies.

City, who accumulates the money so paid to him with a view to providing a fund for the ultimate purchase of the undertakings of the companies. The funds in the hands of the Chamberlain of the City from this source amounted in 1901 to over £70,000.

London, a city and port of entry of Middlesex county, Ontario, Canada, situated 105 miles south-west of Toronto, on the river Thames and on the Grand Trunk, Canadian Pacific, and Lake Erie and Detroit River Railways. It has an electric street railway, and does a large wholesale trade in dry goods, groceries, &c., and export trade in manufactures, live stock, and farm produce. Two hospitals, a normal school, and collegiate institute are among the newer public buildings. The factories had in 1898 an output valued at \$8,726,170, and employed 6000 hands. Total assessment in 1902, \$18,350,360; acreage within the city limits, 4478 acres; exports in the year 1898-99, \$1,490,989; imports, \$3,883,805. Population (1881), 19,746; (1891), 31,977; (1901), 37,981, or, including suburbs of London Junction and Ealing, 45,000.

Londonderry, a maritime county of Ireland, province of Ulster.

Population.—The area of the administrative county in 1900 was 513,388 acres, of which 176,663 were tillage, 219,269 pasture, 367 fallow, 4484 plantation, 25,944 turf bog, 4232 marsh, 58,352 barren mountain, and 24,077 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, does not include the city of Londonderry, now a separate county. The population in 1881 was 164,991; in 1891, 152,009; and in 1901, 144,329, of whom 69,013 were males and 75,316 females, divided as follows among the different religions: Roman Catholics, 65,308; Presbyterians, 45,828; Protestant Episcopalians, 27,687; Methodists, 1440; and other denominations, 4066. The decrease of population between 1881 and 1891 was 7·87 per cent., and between 1891 and 1901, 5·1 per cent. The average number of persons to an acre in 1891 was ·29 of the total population, and 109,168 persons inhabited the rural districts, being an average of 187 persons to each square mile under crops and pasture. The following table gives the degree of education in 1891:—

	Males.	Females.	Total.	Percentage.			
				R.C.	Pr.Ep.	Presb.	Meth.
Read and write	47,737	48,397	96,134	60·5	71·0	81·3	91·2
Read only	8,567	12,546	21,113	17·6	16·9	12·5	5·0
Illiterate	9,220	10,283	19,503	21·9	12·1	6·2	3·8

A Committee of the House of Commons reported in 1896 that the insertion of such provisions in the Acts of the companies tended to weaken the enterprise of the companies as private concerns, whilst the consumer was left without that care of his interests which would be ensured by placing supply under a representative body.

Of the accompanying tables, the first shows the financial condition of the water companies in 1880, 1888, and 1898; the second affords a comparison between the supply, &c., of the companies in 1898, as compared with the figures given in vol. xiv. p. 825.

The percentage of illiterates among Roman Catholics in 1881 was 27·3. In 1891 there were 16 superior schools with 995 pupils (Roman Catholics, 174, and Protestants, 821), and 296 primary schools with 18,411 pupils (Roman Catholics, 7032, and Protestants, 11,379). The number of pupils on the rolls of the National schools on 31st December 1900 was 23,521, of whom 10,000 were Roman Catholics and 13,521 Protestants. The following table gives the births, deaths, and marriages:—

Year.	Births.	Deaths.	Marriages.
1881	4199	3106	800
1891	3574	2810	772
1900	3219	2828	797

In 1900 the birth-rate per thousand was 22·3, and the death-rate 19·6; the rate of illegitimacy was 3·8 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1900 was 102,776, of whom 57,926 were males and 44,850 females. The chief towns in the county are Londonderry (39,873 in 1901), Coleraine (6929 in 1901), Limavady (2692 in 1901).

Administration.—The county is divided into two parliamentary divisions, North and South, the number of registered electors in 1901 being respectively 10,175 and 8922. The rateable value in 1899 was £414,755. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises two urban and four rural sanitary districts.

Agriculture.—The following tables show the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1900:—

Year.	Wheat.	Oats.	Barley, Beans, Rape, &c.	Potatoes.	Turnips.	Flax.	Other Green Crops.	Meadow and Clover.	Total.
1881	1817	74,668	3102	34,437	12,491	18,940	3389	33,047	186,891
1891	1114	69,090	1896	30,236	14,249	11,920	2535	43,829	174,869
1895	697	72,788	1809	30,370	14,743	13,621	1438	47,667	183,133
1900	1084	68,471	1838	28,681	15,153	8,284	3123	50,029	176,668

For 1900 the total value of the cereal and other crops was estimated at £1,403,629. The number of acres under pasture in 1881 was 203,483; in 1891, 202,986; and in 1900, 219,269.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	20,776	462	96,693	30,161	23,946	4666	368,436
1891	21,681	585	111,860	70,540	33,091	6694	459,452
1895	22,212	594	112,148	61,229	30,576	5664	526,122
1900	20,766	696	114,279	67,321	34,417	5736	583,349

The number of milch cows in 1891 was 42,077, and in 1900, 41,176. It is estimated that the total value of cattle, sheep, and pigs for 1900 was £1,595,918. In 1900 the number of holdings not exceeding 1 acre was 1484; between 1 and 5, 1497; between 5 and 15, 5129; between 15 and 30, 4570; between 30 and 50, 2298;

between 50 and 100, 1459; between 100 and 200, 426; between 200 and 500, 124; and above 500, 32—total, 17,019. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901 was 5319, amounting to £1,282,266. The number of loans for agricultural improvements sanctioned under sec. 31 of the Land Act, 1881, between 1882 and 1901, was 147, and the amount issued £10,815. The total amount issued on loan for all classes of works under the Land Improvement Acts from the commencement of operations in 1847 to 31st March 1901 was £75,157.

Fisheries.—In the deep-sea and coast fishery districts of Moville (co. Donegal) 211 boats were registered in 1900, employing 891 hands. In the salmon fishery district of Coleraine, on the river Bann, 784 persons were employed in the same year. (W. H. Po.)

Londonderry, a maritime city, county and parliamentary borough (returning one member), on the river Foyle, 144 miles north-north-west of Dublin. It is an extensive railway centre, being served by the Great Northern, the Belfast and Northern Counties, and the Londonderry, Letterkenny, and Lough Swilly railways, all of which are in direct connexion with the harbour. The Protestant cathedral was enlarged and restored in 1887, and has now a length of 140 feet, exclusive of the tower and vestibule. Shirt-making is the chief industry, and it is estimated that £500,000 is annually expended in wages. The harbour, which is under the jurisdiction of the Irish Society, has now a depth of 33 feet of water at high tide and 12 feet at low tide. The number of vessels registered in the port in 1900 was 22 of 10,323 tons. In the same year the total number of vessels that entered was 1554 of 297,352 tons; 928 of 185,959 tons cleared. The total foreign and colonial imports, which included 1,102,300 cwt. of maize, amounted to £329,932. There are valuable salmon fisheries on the Foyle, which in 1900 employed 891 persons. In 1898 Londonderry was constituted one of the six county boroughs which have separate county councils. Population (1881), 29,162; (1891), 33,200; (1901), 39,873. The rateable value in 1900 was £99,887.

Long Branch, a city of Monmouth county, New Jersey, U.S.A. It is on the east coast, a short distance south of New York Bay, and is reached by lines of the Pennsylvania and the Central of New Jersey railways, and, in the summer, by steamboats from New York. It is a very popular seaside resort. The city lies back from the edge of a cliff, 25 to 30 feet high, at the foot of which extends a magnificent beach five miles in length. Most of the city is built on Ocean Avenue, which follows the edge of the cliff and forms a drive five miles long. The city contains many fine private residences, several large hotels, and multitudes of boarding-houses. Population (1880), 3833; (1890), 7231; (1900), 8872, of whom 1431 were foreign-born and 987 were negroes.

Longford, an inland county of Ireland, province of Leinster.

Population.—The area of the administrative county in 1900 was 257,770 acres, of which 62,953 were tillage, 140,427 pasture, 129 fallow, 3595 plantation, 30,642 turf bog, 4842 marsh, 1511 barren mountain, 13,671 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, is identical with the old judicial county. The population in 1881 was 61,009; in 1891, 52,647; and in 1901, 46,581, of whom 23,765 were males and 22,816 females, divided as follows among the different religions:—Roman Catholics, 42,669; Protestant Episcopalians, 3406; Presbyterians, 251; Methodists, 194; and other denominations, 61. The decrease of population between 1881 and 1891 was 13.70 per cent., and between 1891 and 1901, 11.5. The average number of persons to an acre in 1891 was 0.20, and of the total population, 48,820 inhabited the rural districts, being an average of 155 persons to each square mile under crops and pasture. The following table shows the degree of education in 1891:—

	Males.	Females.	Total.	Percentage.			
				R. C.	Pr. Ep.	Presb.	Meth.
Read and write	16,938	15,991	32,929	67.0	89.0	92.7	96.3
Read only	3,192	3,586	6,778	15.0	5.4	1.9	1.6
Illiterate	4,110	3,962	8,072	18.0	5.6	5.4	2.1

The percentage of illiterates among Roman Catholics in 1881 was 24.8. In 1891 there were 4 superior schools, with 92 pupils (all Roman Catholics), and 117 primary schools, with 7597 pupils (Roman Catholics, 6805, and Protestants, 792). The number of pupils on the rolls of National schools on 31st December 1900 was 7941, of whom 7198 were Roman Catholics and 743 Protestants.

The following table gives the number of births, deaths, and marriages in the years specified:—

Year.	Births.	Deaths.	Marriages.
1881	1734	1050	270
1891	1065	811	193
1900	929	963	186

In 1900 the birth-rate per 1000 was 19.9, and the death-rate 20.7; the rate of illegitimacy was .3 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1900 was 56,305, of whom 28,597 were males and 27,708 females. The chief towns in the county, with their populations in 1901, were Longford, 3733; Granard, 1700.

Administration.—The county is divided into two parliamentary divisions, North and South, the number of registered electors in 1901 being respectively 5043 and 5311. The rateable value in 1900 was £153,098. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises two urban and three rural sanitary districts.

Agriculture.—The following tables show the acreage under crops, including meadow and clover, and the amount of live stock, in 1881, 1891, 1895, and 1900:—

Year.	Wheat.	Oats.	Barley, Rape, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881	307	18,670	469	13,102	2621	1688	37,599	74,756
1891	397	14,158	308	11,782	2666	2177	39,286	70,718
1895	164	12,605	208	10,449	2105	1670	37,552	64,738
1900	271	10,398	126	9,818	1840	2051	38,450	62,954

In 1900 the total value of the cereal and other crops was estimated at £390,288, the smallest amount of any Irish county. The number of acres under pasture in 1881 was 125,830; in 1891, 130,866; and in 1900, 140,427.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	7526	3066	51,557	24,140	17,900	7978	232,324
1891	8843	3668	63,189	33,380	22,660	9079	251,395
1895	8904	3854	53,404	27,068	21,371	7890	272,355
1900	8039	4198	66,225	31,621	22,781	8010	309,473

The number of milch cows in 1891 was 17,580, and in 1900, 17,024. It is estimated that the total value of cattle, sheep, and pigs for 1900 was £917,502. In 1900 the number of holdings not exceeding 1 acre was 1172; between 1 and 5, 857; between 5 and 15, 2464; between 15 and 30, 2676; between 30 and 50, 1185; between 50 and 100, 588; between 100 and 200, 186; between 200 and 500, 72; and above 500, 7—total, 9207. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901, was 1873, amounting to £416,903. The number of loans for agricultural improvements sanctioned under section 31 of the Land Act, 1881, between 1882 and 1901, was 334, and the amount issued was £25,133. The total amount issued on loan for all classes of works under the Land Improvement Acts from the commencement of operations in 1847 to 31st March 1901 was £184,151. (W. H. Po.)

Long Island City, formerly a city of New York state, U.S.A., capital of Queens county, now a part of the borough of Queens, one of the five boroughs which compose the city of New York. It is near the western end of Long Island, in the south-eastern part of the state. It was incorporated in the city of New York, 1st January 1898, and constitutes the first ward in Queens borough. With a water front of ten miles on East River and

Long Island Sound, it has some commerce, but it is known chiefly as a manufacturing place. In 1890 it contained 325 manufacturing establishments, with a capital of \$12,823,594. They employed 4691 persons, and paid in wages \$3,066,132, while the products had a total value of \$16,200,226. The principal manufacturing industries are oil-refining, the making of chemicals, asphalt, and carpets. Population (1880), 17,129; (1890), 30,506; (1900), 48,272, of whom 15,899 were foreign-born.

Longstreet, James (1821—), American general in the Confederate army, was born on 8th January 1821 in Edgefield district, South Carolina, and graduated at West Point in 1842. He served through the Mexican war with distinction, was twice breveted for conduct, and severely wounded at Churubusco. When the Southern States seceded he resigned, and became a brigadier-general in the Confederate army. His brigade fought in the battle of Bull Run (July 1861). Divisions were not

GENERAL LONGSTREET.

formed in the Confederate army until that autumn, and corps not until a year later. Longstreet's division, already distinguished in many battles, became the nucleus of the 1st corps, which he commanded until the end of the war. At Gettysburg he disapproved of the attack because of the exceptionally strong position of the Federal forces. He has been charged with tardiness in getting into the action, but his delay was in part authorized by Lee to await an absent brigade, and in part was the result of instructions to conceal his movements, which caused circuitous marching. The most desperate and most conspicuous fighting in the battle was conducted by Longstreet. In September 1863 he took his corps to Georgia, where he made the successful assault upon Rosecrans at Chickamauga. In November he commanded the expedition against Knoxville, which proved a failure. In 1864 he rejoined Lee's army in Virginia, and on 6th May arrived upon the field of the Wilderness as the Confederate right had been turned and routed. His attack was a model of impetuosity and skill, and drove the enemy back until their entire force upon that flank was in confusion. At this critical moment, as

Longstreet in person, at the head of fresh troops, was pushing the attack in the forest, he was fired upon by mistake by a flanking force of his own men, and desperately wounded by a shot through the neck. This mischance stayed the Confederate assault for four hours, and enabled the enemy to provide effective means to meet it. In October 1864 he resumed command of his corps, which he retained until the surrender, although paralysed in his right arm. During what is known as the Reconstruction Period, Longstreet advised acceptance of terms of re-admission into the Union which disfranchised the leading men of the South, himself among them. He believed that if these were rejected harder terms would be enforced. In fact, the ballot was afterwards given to the recently emancipated slaves, and the state governments were turned over to them. For this advice Longstreet was bitterly assailed by most of the Southern press. But as time assuaged prejudice, he regained the respect and affection of former days, when his soldiers, proud of his record, called him "General Lee's War-horse." Longstreet's merit lay in sound strategic judgment, in instinctive appreciation of what it was possible for his soldiers to do, and in a stubborn courage rising highest when all seemed lost. After the war he held several important civil offices, among them those of minister to Turkey under President Grant, and Commissioner of Railways under Presidents McKinley and Roosevelt.

Longton, a municipal borough and market-town of Staffordshire, England, $2\frac{1}{2}$ miles by rail south-east of Stoke-upon-Trent, within which parliamentary borough it is included. There are a town-hall, public baths, a theatre, a technical institute and public library, a public park, and a good secondary school; also an organized school of science and a school of art. The town is in the Potteries district, and in the neighbourhood of coal and iron mines. Area, 1934 acres. Population (1881), 29,915; (1891), 34,327; (1901), 35,825.

Longwy, a fortified town and railway station, arrondissement of Briey, department of Meurthe-et-Moselle, France, 63 miles in direct line west-north-west of Nancy on the railway from Longuyon to Arlon, and on a plateau overlooking the Chiers, a right-bank affluent of the Meuse, near the frontiers of Belgium and Luxemburg. It comprises an upper and a lower town; the former, a strong place on a hill, 390 feet above the Chiers valley, commands the Luxemburg road, and is strengthened by outlying fortifications. There is garrison accommodation for 5000 men and 800 horses. The lower town is the industrial centre. The 17th-century church has a lofty square tower, the Hôtel de Ville dates from 1730, and there is a fine hospital. Iron is extensively mined in the district, and supplies numerous blast furnaces. Several important iron and steel works are in operation, and metal utensils and porcelain are manufactured. Longwy (*Longus vicus*) has been fortified since the 17th century. It was the first border stronghold captured by the Prussians in 1792, and was again taken in the wars of 1815 and 1871. Population (1881), 3701; (1891), 4729; (1901), 9235.

Lönnrot, Elias (1802–1884), the Finnish philologist and discoverer of the *Kalevala*, was born at Nyland in Finland on 9th April 1802. He began life as an apothecary's assistant, but entered the university of Åbo in 1822, and after taking his successive degrees, became a physician in 1832. But before this, as early as 1827, he had begun to publish contributions to the study of the ancient Finnish language, and to collect the national ballads and folk-lore, a field which was at that time wholly uncultivated. In 1833 he settled as a doctor in the country district of Kajana, and began to travel

throughout Finland and the adjoining Russian provinces in his leisure time, garnering the harvest of songs and legends. In this way he was able to put together, as described in vol. ix. pp. 219-220, the great epic of Finland, the *Kalevala*, the first edition of which he published in 1835; he continued to add to it, and in 1849 issued a much larger and completer text. In 1840 Lönnrot issued his very important collection of the *Kanteletar*, or folk-songs of ancient Finland, which he had taken down from oral tradition. The *Proverbs of Finland* followed in 1842. In 1853, on the death of Castrén, Lönnrot became professor of the Finnish language and literature at the high school of Helsingfors; he retired from this chair in 1862. His whole life, which closed on 19th March 1884, was dedicated to the study and the elucidation of the obscure and difficult native language of Finland, and his contributions to philology, and particularly to folk-lore, place Lönnrot in the first rank of modern European scholars. (E. G.)

Lorain, a city of Lorain county, Ohio, U.S.A., on Lake Erie, at the mouth of the Black river, and the Cleveland, Lorain, and Wheeling, and the New York, Chicago, and St Louis railways, at an altitude of 609 feet. It has a good harbour and considerable lake commerce, especially in coal. Population (1880), 1595; (1890), 4863; (1900), 16,028, of whom 4730 were foreign-born and 329 were negroes.

Lorca, a town of Spain, in the province of Murcia. The population in 1897 was 59,624. The old part of the town, with narrow, irregular streets, contrasts with the modern part, which has broad streets and squares, and many fine public buildings—the bishop's palace, theatre, town-house, hospitals, courts of justice, and a new bridge over the river Sangonera. There is an important trade in agricultural products and live stock, as well as manufactures of woollen stuffs, leather, and porcelain.

Lorenzo Marques, or LOURENÇO MARQUES, capital of Portuguese East Africa, or Mozambique, on Delagoa Bay, close to the mouth of the Espirito Santo or English river. Since the opening in 1888 of the railway to Pretoria the town has increased in commercial and material prosperity. Extensive harbour works, estimated to cost over a million of money, were begun at the end of the 19th century. Meanwhile vessels generally discharge into lighters, though there are three piers (two only small). The district of LORENZO MARQUES has a population of 3000 Europeans and 200,000 natives.

Loreto, a famous pilgrimage centre and episcopal see of the province of Ancona, the Marches, Italy, 15 miles south-south-east of Ancona by rail to Brindisi. The shrine of the Virgin's House (Casa Santa) is visited annually by some 50,000 pilgrims, the chief festival being held on 7th and 8th September. Population (1881), 5183; (1900), 5000.

Loreto, an interior department of northern Peru, with an area of 32,727 square miles, and in 1896 a population of 70,676. It contains four provinces—Alto-Amazonas, Bajo-Amazonas, Moyobamba, and Huallaga. The town of Moyobamba has a population of 10,000.

Lorient, chief town of arrondissement and railway station, department of Morbihan, France, 37 miles west by north of Vannes; a military port of the first class, a fortified place of the third class, and the first port for naval construction in France. The Government ship-building yards on the Caudan peninsula cover an area of about 38 acres, and contain nine slips for ships and frigates, and two others for smaller vessels, besides forges with twenty-eight furnaces, and workshops for iron ship-building; on the right bank of the river are the graving

dock, called Clermont-Tonnerre, a covered slip 232 feet by 81, and three other slips. In all, eighty furnaces are connected with the dockyard. The roadstead is provided with eight lighthouses. In 1900, 98 vessels of 17,694 tons entered, and 111 vessels of 17,584 tons (British three-fourths) cleared, in addition to the coasting trade. Population (1881), 30,502; (1891), 34,620; (1901), 44,082.

Loris-Mélikof, Michael Tarielovitch, COUNT (1825 (?)—1888), Russian statesman, son of an Armenian merchant, was born at Tiflis in 1825 or 1826, and educated in St Petersburg, first in the Lazaref School of Oriental Languages, and afterwards in the Guards' Cadet Institute. He joined a hussar regiment, and four years afterwards (1847) he was sent to the Caucasus, where he remained for more than twenty years, and made for himself during troublous times the reputation of a distinguished cavalry officer and an able administrator. In the latter capacity, though a keen soldier, he aimed always at preparing the warlike and turbulent population committed to his charge for the transition from military to normal civil administration, and in this work his favourite instrument was the schoolmaster. In the Russo-Turkish war of 1877-78 he commanded a separate corps d'armée on the Turkish frontier in Asia Minor. After taking the fortress of Ardahan, he was repulsed by Mukhtar Pasha at Zevin, but subsequently defeated his opponent at Aladja Dagh, took Kars by storm, and laid siege to Erzerum. For these services he received the title of Count. In the following year he was appointed temporary governor-general of the region of the Lower Volga, to combat an outbreak of the plague, and the measures he adopted proved so effectual that he was transferred to the provinces of Central Russia to combat an epidemic of a still more dangerous kind, the revolutionary agitation of the Nihilists and Anarchists, who had adopted a policy of terrorism, and had succeeded in assassinating the governor of Khar-koff. His success in this struggle led to his being appointed chief of the Supreme Executive Commission which had been created in St Petersburg for the purpose of dealing with the revolutionary agitation in general. Here, as in the Caucasus, he showed a decided preference for the employment of ordinary legal methods rather than exceptional extra-legal measures, and an attempt on his own life soon after he assumed office did not shake his convictions. In his opinion the best policy was to strike at the root of the evil by removing the causes of popular discontent, and for this purpose he recommended to the Tsar a large scheme of administrative and economic reforms. Alexander II., who was beginning to lose faith in the efficacy of the simple method of police repression hitherto employed, lent a willing ear to the suggestion; and when the Supreme Commission was dissolved in August 1880, he appointed Count Loris-Mélikof Minister of the Interior with exceptional powers. The proposed scheme of reforms was at once taken in hand, but it was never carried out. On the very day in March 1881 that the emperor signed a ukaz creating several commissions, composed of officials and eminent private individuals, who should prepare reforms in various branches of the administration, he was assassinated by Nihilist conspirators; and his successor, Alexander III., at once adopted a strongly reactionary policy. Count Loris-Mélikof immediately resigned, and lived in retirement until his death, which took place at Nice on 22nd December 1888. (D. M. W.)

Lörrach, a town of Germany, grand-duchy of Baden, in the valley of the Wiese, 6 miles by rail north-east of Basel. It is the seat of considerable industry—calico and shawl printing, cloth, silk, chocolate, cotton, hardware, furniture, and dyeing, and a trade in wine, fruit, and timber. Population (1885), 6795; (1900), 10,347.

Lorraine. See ALSACE-LORRAINE, and the French departments MEUSE and MEURTHE-ET-MOSELLE.

Los Angeles, a city of California, U.S.A., capital of Los Angeles county, on Los Angeles river, near the foot of San Gabriel range, in the southern part of the state, at an altitude of 300 feet. It is the largest and most important city of southern California, and the second in size in the state. Its site is, in the main, level, and the plan is quite regular, with broad streets, well paved in the business section, and shaded with eucalyptus and pepper trees. The residential portions are in the main constructed in detached cottages and villas, and contain many fine houses, with ample grounds beautified with tropical vegetation. The city derives its water supply by gravity from Los Angeles river, and is well sewered. It is divided into nine wards. Situated only 14 miles from the Pacific coast, and under the influence of prevailing westerly winds from the ocean, the atmosphere is necessarily heavily charged with moisture, but the annual rainfall is small and occurs in the winter. On account of this slight rainfall and the balmy temperature Los Angeles and its neighbourhood enjoy a great reputation as a health resort, especially for consumptives. This has done much in the way of settling and developing the region. The death-rate in 1900 was 18.01; in 1890 it was 20. The city is situated upon the Southern Pacific and the Atchison, Topeka, and Santa Fé railways. The surrounding region is, when irrigated, extremely fertile, producing oranges, lemons, figs, and other semi-tropical fruits. As surface water for irrigation is scarce, thousands of artesian wells have been bored to secure a supply from the underlying gravels. Indeed, the region between San Bernardino and Los Angeles is the most important artesian well country in the world. Los Angeles had, in 1900, 1415 manufacturing establishments, with a total capital of \$11,742,838. They employed 8044 hands, and 939 salaried officials and clerks, and their products were valued at \$21,297,537. These products were very varied in character. Among the educational institutions of the city are Occidental College, a Presbyterian school, founded in 1887, and St Vincent's College, Roman Catholic, founded in 1865. The assessed valuation of real and personal property in 1900, on a basis of about 60 per cent. of the full value, was \$67,599,920; the net debt of the city was \$1,417,791, and the rate of taxation was \$28.70 per \$1000. Population (1880), 11,183; (1890), 50,395; (1900), 102,479, of whom 19,964 were foreign-born and 2131 were negroes. There were, in 1900, 28,508 persons of school age (5 to 20 years inclusive). Out of 33,049 males of voting age, 886 were illiterate (unable to write).

Losoncz, a corporate town of Upper Hungary, in the county of Nógrád, 101 miles by rail north-north-east of Budapest, with 8225 inhabitants in 1891 and 9530 in 1901. Its chief industries include enamelling, cloth, and glue factories, and a steam mill. It possesses an upper gymnasium, a normal school, a theatre, and a public library. It was almost totally destroyed in 1849 by the Russians, but is again flourishing. The first Hungarian state railway was laid from Budapest to Losoncz, and this is still the main line connecting central Hungary with Berlin.

Lossiemouth, a police burgh of Elginshire, Scotland, embracing the three villages of Lossiemouth, Branderburgh, and Stotfield, at the mouth of the Lossie river, 5½ miles by rail north-north-east of Elgin, of which it is the port. The harbour, which has an area of nearly 6 acres, and a depth varying from 8 to 20 feet, is accessible to vessels of 600 tons, having been deepened at a cost (by Government loan) of £20,000. There are a

town-hall and swimming-baths. Water is supplied. The industries are boat-building and fishing; in 1898 the value of the fish caught was £14,275. The port is the leading one in the district. The churches are Established, United Free, Baptist, and Episcopal. A public school had an average attendance of 822 in 1898-99. There is an excellent golf-course. Population (1881), 3497; (1901), 3889.

Lossing, Benson John (1813-1891), American historical writer, was born in Beekman, New York, on 12th February 1813. After editing newspapers in Poughkeepsie he became an engraver on wood, and removed to New York in 1839 for the practice of his profession, to which he added that of drawing illustrations for books and periodicals. He likewise wrote or edited the text of numerous publications in a long and active career as a writer. His *Pictorial Field-Book of the Revolution* (first issued in 30 parts, 1850-52, and then in 2 volumes) was a pioneer work of value in American historical literature. In its preparation he travelled some 9000 miles during a period of nearly two years; made more than a thousand sketches of extant buildings, battlefields, &c.; conversed with local authorities; and presented his accumulated materials in a form serviceable to the topographer and interesting to the general reader. Similar but less characteristic and less valuable undertakings were a *Pictorial Field-Book of the War of 1812* (1868), and a *Pictorial History of the Civil War in the United States of America* (3 vols. 1866-69). His other books, between 1840 and his death, were numerous: an *Outline History of the Fine Arts*; many illustrated histories, large and small, of the United States; popular descriptions of Mount Vernon and other localities associated with famous names; and biographical sketches of celebrated Americans, of which *The Life and Times of Major-General Philip Schuyler* (2 vols. 1860-73) was the most considerable. He died at Dover Plains, New York, on 3rd June 1891.

(C. F. R.)

Lot, a department of the south-west of France, watered by the Lot and the Dordogne.

Area, 2018 square miles. From 271,514 in 1886 the population decreased to 223,736 in 1901. In 1899 the births numbered only 3849 against 5630 deaths, 97 of the births being illegitimate; marriages numbered 1570. In 1896 there were 841 schools, with 31,000 pupils, and only 2 per cent. of the population was illiterate. The area under cultivation, confined by the rocks of the high plateaux, measured in 1896 only 1,023,052 acres, of which 588,132 acres were arable land and 69,190 acres vineyards. The land in wheat returned in 1899 a value of £643,000; rye, £83,000; oats, £86,000; vines, £189,000. The natural pastures yielded £215,900 in 1898. Chestnuts were then valued at £61,200, and walnuts at nearly as much. The rearing of sheep is carried on in a specially important degree. While the horses of the department in 1899 numbered only 9530, its asses 5220, and its cattle 72,630, its sheep amounted to 428,600—a number exceeded by only ten other departments of France. In 1898, 4000 tons of coal and 9200 tons of iron were mined. Metallurgy is in a backward state. Tanning and the manufacture of coarse cloths are more advanced. Cahors, the chief town, has a population of 13,981 (1901).

Lot-et-Garonne, a department of the south-west of France, watered by the two rivers naming it.

Area, 2079 square miles. The population declined from 307,437 in 1886 to 276,607 in 1901. In 1899 the births numbered 4143, of which 145 were illegitimate; deaths, 6132; marriages, 1987. The schools in 1896 numbered 747, with 31,000 pupils, and the illiterate constituted 5 per cent. of the population. In 1896, out of 1,181,206 acres of cultivated land, 733,929 acres were ploughland and 135,912 acres vineyards. The wheat crop of 1899 was valued at £883,000; the other cereals returned light values—potatoes, £448,000; natural pastures, £324,000; tobacco, £140,000. Lot-et-Garonne in 1899 yielded plums to the value of £198,000. Its vines in 1899 returned the value of £564,090. The live stock of that year included 21,950 horses, 269,220 cattle, 156,530 sheep, and 65,200 pigs. In 1898 there were mined 25,500 tons of iron, and 20,050 metric tons of cast-iron

were produced, valued at £64,000. The alimentary industries, particularly the rearing of pigs, are in a very thriving state. Agen, the capital, had 22,482 inhabitants in 1901.

Loti, Pierre [the pen-name of LOUIS MARIE JULIEN VIAUD] (1850—), French author, was born at Rochefort on the 14th of January 1850. The Viauds are an old Protestant family, and Pierre Loti has consistently adhered, at least nominally, to the faith of his fathers. Of the picturesque and touching incidents of his childhood he has given a very vivid account in *Le Roman d'un Enfant* (1890). His education began in Rochefort, but at the age of seventeen, being destined for the navy, he entered the great French naval school, Le Borda, and gradually rose in his profession. His pseudonym is said to be due to his extreme shyness and reserve in early life, which made his comrades call him after *le Loti*, an Indian flower which loves to blush unseen. He was never given to books or study (when he was received at the French Academy, he had the courage to say, "Loti ne sait pas lire"), and it was not until his thirtieth year that he was persuaded to write down and publish some curious experiences at Constantinople, in *Aziyadé*, a book which, like so many of Loti's, seems half a romance, half an autobiography. He proceeded to the South Seas, and on leaving Tahiti published the Polynesian idyl, originally called *Rarahu*, which was reprinted as *Le Mariage de Loti* (1880), and which first introduced to the wider public an author of remarkable originality and charm. He now became extremely prolific, and in a succession of volumes chronicled old exotic memories or edited the journal of new travels. *Le Roman d'un Spahi*, a record of the melancholy adventures of a soldier in Senegambia, belongs to 1881. In 1882 Loti issued a collection of short studies under the general title of *Fleurs d'Ennui*. In 1883 he achieved the widest celebrity, for not only did he publish *Mon Frère Yves*, a novel describing the life of a French bluejacket in all parts of the world—perhaps, on the whole, to this day his most characteristic production—but he was involved in a public discussion in a manner which did him great credit. While taking part as a naval officer in the Tongking war, Loti had exposed in a Parisian newspaper a series of scandals which followed on the capture of Hué, and, being recalled, was suspended from the service for more than a year. He continued for some time nearly silent, but in 1886 he published a novel of life among the Breton fisher-folk, called *Pêcheur d'Islande*, which has been the most popular of all his writings. In 1887 he brought out a volume of extraordinary merit, which has never received the attention it deserves; this is *Propos d'Exil*, a series of short studies of exotic places, in his peculiar semi-autobiographic style. The fantastic novel of Japanese manners, *Madame Chrysanthème*, belongs to the same year. Passing over one or two slighter productions, we come in 1890 to *Au Maroc*, the record of a journey to Fez in company with a French embassy. A collection of strangely confidential and sentimental reminiscences, called *Le Livre de la Pitié et de la Mort*, belongs to 1891. Loti was on board his ship at the port of Algiers when news was brought to him of his election, on the 21st of May 1891, to the French Academy. After he became an Immortal the literary activity of Pierre Loti somewhat declined. In 1892 he published *Fantôme d'Orient*, another dreamy study of life in Constantinople, a sort of continuation of *Aziyadé*. He has described a visit to the Holy Land, somewhat too copiously, in three volumes (1895-96), and has written a novel, *Ramuntocho* (1897), a story of manners in the Basque province, which is quite on a level with his best writings. In 1900 he visited British India, with the view of describing what he saw, but it was understood that he

was disappointed; in 1901 he was writing from Peking his impressions of China after the war. At his best, Pierre Loti is unquestionably the finest descriptive writer of the day. In the delicate exactitude with which he reproduces the impression given to his own alert nerves by unfamiliar forms, colours, sounds, and perfumes, he is without a rival. But he is not satisfied with this exterior charm; he desires to blend with it a moral sensibility of the extremest refinement, at once sensual and ethereal. Many of his best books are long sobs of remorseful memory, so personal, so intimate, that an English reader is amazed to find such depth of feeling compatible with the power of minutely and publicly recording what is felt. In spite of the beauty and melody and fragrance of Loti's books, it is not to be denied that his mannerisms are apt to pall upon the reader, and that his more recent books of pure description have been rather empty. His greatest successes were gained in the species of confession, half-way between fact and fiction, which he essayed in his earlier books. When all his limitations, however, have been rehearsed, Pierre Loti remains, in the mechanism of style and cadence, one of the most original and most perfect writers of the second half of the 19th century. Whether his matter is worthy of the form in which he sets it is a question which must be left to the temperament of the individual reader.

Loubet, Émile (1838—), President of the French Republic, son of a peasant proprietor at Marsanne, in the department of the Drôme, was born on 31st December 1838. He studied law, and established himself at the small town of Montélimar, of which he was mayor in 1870 and parliamentary representative in 1876. He steadily supported the Moderate Republican party; in 1885 he was elected to the Senate, and in 1887 received the portfolio of public works in the Tirard cabinet, but resigned in the following year. In 1892 he himself formed a ministry at the request of President Carnot, but the excitement of the Panama scandals overthrew his administration in the winter of the same year—a circumstance which his political opponents used against him when he was elected President. That no imputation rested upon M. Loubet personally was shown by his election to the highly honourable office of President of the Senate in 1895; and the prestige thus acquired contributed to his elevation to the presidency of the Republic on the sudden death of President Faure in February 1899. Coming to office at a very difficult period, when the nation was rent by the Dreyfus controversy, and the upper classes of Society seemed united with large sections of the Church and the Army in opposition to the Republic, M. Loubet underwent severe trials, and was exposed to unexampled insults, over which he gradually triumphed by dint of patience, fortitude, and the exhibition of a perfect simplicity of life. He retained his predecessor's advisers as long as possible; but when a reconstruction eventually became necessary, he called upon Republicans of all shades to concentrate for the salvation of the Republic, and for the first time Moderates and Socialists were seen sharing in the same Administration. The cabinet thus formed by M. Waldeck-Rousseau displayed unexpected vitality, though no doubt much assisted by the general aversion from disturbance during the great Exhibition of 1900. M. Loubet had the satisfaction of seeing "l'affaire Dreyfus" at last driven into the background, and the Nationalist and anti-Semite agitation discomfited by a resolute vindication of republican institutions. On 22nd September 1900 a successful monster banquet in Paris to the provincial mayors gave occasion for a great demonstration of loyalty of the country as a whole to its Government; and in

September 1901 M. Loubet's triumph was signalized by the visit to France of the Tsar and Tsarina of Russia, on which occasion the alliance of the two countries was once more proclaimed.

Loughborough, a municipal borough (incorporated 1888) and market-town, in the Loughborough parliamentary division of Leicestershire, England, on the Soar, 11 miles north by west of Leicester by rail. Modern erections are a free library, a philharmonic hall, a theatre, Queen's memorial baths, and a drill hall. The infirmary has been enlarged. Area, 3045 acres. Population (1881), 14,552; (1891), 18,196; (1901), 21,508.

Louisiade Archipelago. See MELANESIA and NEW GUINEA.

Louisiana, one of the southern states of the American Union. It is composed of 59 parishes or counties. In 1880 the population was 939,946; in 1890 it was 1,118,587. In 1900 it was 1,381,625. The increase between 1890 and 1900 was 23·5 per cent. The density of population in 1890 was 24·6; in 1900 it was 30·4. In 1890 there were 559,350 males and 559,237 females; 558,395 white and 560,192 coloured; 1,068,840 native-born and 49,747 foreign-born. There are 104 incorporated cities, towns, and villages in the state, of which only 7 had in 1900 more than 5000 inhabitants, and 3 more than 10,000. These three were New Orleans, with 287,104 inhabitants; Shreveport, with 16,013; and Baton Rouge, with 11,269.

Education.—The number of children enrolled in public schools in 1896 was 169,947. In 1899 the number was 196,169. Of these 121,936, or 62 per cent., were white, and 74,233, or 38 per cent., were coloured. The number of pupils reported as attending private schools in 1899 was 14,694, of whom 11,896 were white and 2798 were coloured. To these may be added 10,000 children not reported. The number of children of school age in 1900 was 404,757. Thus the percentage of children educated was 54. The average attendance in the public schools was, whites, 90,187; coloured, 56,136; total, 146,323. The number of public school teachers employed was 4157; the number of private teachers was 645. The average length of school session was six months. Of the state tax of six mills on the dollar, 1½ mills are devoted to the public schools, or ¼ of the gross income of the state revenue. In addition to this, every male inhabitant of twenty-one years and over is obliged to pay a poll-tax of one dollar for the support of the schools. The revenue in 1899 was \$1,126,112. There are about thirty high schools; an industrial college at Ruston, and one at Lafayette; a state normal school at Natchitoches; the Southern University for negroes at New Orleans; the State University and Agricultural and Mechanical College at Baton Rouge; and the Louisiana Chautauqua at Ruston. A textile school will be established in the state, as well as a biological station for fish and fisheries. The Tulane University of Louisiana at New Orleans includes departments of medicine and law, a college of arts and sciences, and one of technology, the Newcomb College for Women, a department for teachers, and a university department for graduate study. There are two colleges of Jesuits, a number of schools and convents of the Catholic denomination; Centenary College, Methodist; Silliman Collegiate Institute, Presbyterian; Keachie College, Baptist; and in New Orleans three sectarian colleges for negroes.

Public Institutions.—There are an insane asylum at Jackson, a lepers' home in Iberville parish, and an institution for the blind and one for the deaf at Baton Rouge. There is a charity hospital at Shreveport, and one at New Orleans. The hospital at New Orleans had, in 1899, 9141 resident patients, and 21,803 patients were treated in the dispensary.

Religion.—The chief denominations are as follows:—Catholics, 355,000; Baptists, 107,200; Southern Methodists, 28,000; Presbyterians, 6590; Episcopalians, 7704; Jews, 11,000. There are also a number of Lutherans and Unitarians. The Protestant denominations count as members of the church only those who have made profession of faith.

Agriculture.—About 4,000,000 acres of land are cultivated. There are 3,000,000 acres of state public lands and large areas of United States public lands subject to homestead entry. The crops produced yearly are valued at \$75,000,000. In 1890 the product of Indian corn was 13,081,954 bushels; of oats, 297,271 bushels; of tobacco, 46,845 lb; of rice, 75,645,433 lb (clean rice); of Irish potatoes 375,842 bushels; of sweet potatoes, 1,912,080 bushels;

of cow-pease, 78,682 bushels; and of broom corn, 11,420 lb. In 1900 the product of rice was 902,857 bushels, rough; of corn, 12,759,277 bushels; of oats, 408,170 bushels; of hay, 328,817 bales; of potatoes, 1,275,989 bushels; of sorghum, 13,132 bushels; the number of horses and mules was 275,802; of cattle, 338,369; of sheep, 133,944; of hogs, 198,490. Oranges, lemons, figs, olives, and grapes are also produced, and the fish and oysters are famous.

Sugar.—Of sugar there were produced in 1880, 121,886 tons of 2240 lb; in 1890, 215,843 tons; in 1898, 245,511 tons. Of molasses there were produced in 1898, 24,952,188 gallons.

Cotton.—Louisiana ranks seventh as a cotton-producing state. In 1890 the cotton acreage was 1,270,154, and the number of bales produced 659,180. In 1807-98 there were 1,245,000 acres producing 740,000 bales, or an average of ⅓ bales per acre; in 1898-99 there were 1,292,000 acres producing 590,000 bales, or an average of ⅔ bales per acre. The falling-off in the average yield per acre was due to unfavourable weather. In 1898-99 there were 1595 looms and 65,352 spindles. In 1899-1900 there were 1673 looms and 67,878 spindles. The number of bales of cotton consumed was 16,420.

Lumber.—The timber indigenous to the state consists of yellow pine, cypress, and native southern hardwoods. The eastern pine belt is composed of the longleaf pine, interspersed with some loblolly. It covers an area of about 3900 square miles. The south-western pine belt contains the heaviest growth of longleaf pine timber in the world, covering an area of about 4200 square miles. It merges into the shortleaf forest, which occupies an area of about 7000 square miles, and is in places intermixed with loblolly pine and deciduous hardwoods. The cypress forests of the alluvial and overflowed lands in the southern portions of the state are among the largest and the most heavily timbered in the world. They produce annually about 300,000,000 board feet of lumber. The hardwoods are found in the river bottoms throughout the state. The manufacture of lumber aggregates 600,000 board feet each year, valued at about \$6,000,000.

Minerals.—There is a sulphur bed in Calcasieu parish of an average thickness of 100 feet. At a depth of about 425 feet the production in 1896 was 4200 tons, and in 1897 a little over 1000 tons; in 1900 it was closed. A salt mine at Petite Anse produced, in 1890, 39,978 short tons of salt of remarkable purity; and in 1896, 24,236 tons.

Manufactures.—The condition of manufactures in 1890 and 1900 is shown by the following table:—

	1890.	1900.	Per cent. of increase.
Number of establishments	2,613	4,350	66·5
Capital	\$34,754,121	\$113,084,294	225·4
Salariéd officials, clerks, &c.	3,524 ¹	3,944	11·9
Salaries	\$3,036,995 ¹	\$3,090,185	1·8
Wage-earners	28,377	42,210	48·7
Total wages	\$10,122,569	\$15,385,715	52·0
Miscellaneous expenses	\$3,760,753	\$7,999,870	112·7
Cost of materials used	\$33,282,724	\$82,299,893	147·3
Value of products	\$57,806,713	\$121,181,683	109·6

The manufacturing industries are for the most part closely related to the products of the soil, as is shown by the following statistics:—

Industry.	Capital.	Wage-earners.	Products.
Sugar and molasses refining	\$52,799,105	6,504	\$47,891,691
Lumber and timber products	20,093,044	10,171	17,408,513
Cotton-seed oil and cake .	4,622,569	1,317	7,026,452
Rice, cleaning and polishing	1,818,144	412	5,736,451

New Orleans is the principal centre of manufacturing, the number of establishments, number of wage-earners and value of products for this city constituting 35·1, 46·2, and 52·5 per cent. respectively of the totals for the entire state.

Debt and Assessed Valuation.—The total bonded debt of Louisiana, bearing interest in 1899, was \$10,877,800; the floating debt was \$914,397. The total valuation of real and personal property in 1890 was \$495,301,597. The assessed valuation in 1890 was \$234,350,791; and, in 1899, \$267,723,052. The rate of taxation is six mills on the dollar of the assessed valuation, which should have yielded in 1899 a revenue of some \$1,606,338, less 8½ per cent. to cover cost of collection and also non-collections.

¹ Includes proprietors and firm members, with their salaries.

Banks.—The state bank examiner gives the following figures for state banks in Louisiana in October 1900:—

Capital stock	\$7,015,210
Deposits	36,378,809
Real estate	1,803,071
Specie	2,258,334
Currency	2,302,716

Railways.—The total length of railways in 1880 was 652 miles; in 1890, 1740 miles; in 1899, 2410 miles. The chief lines are the Southern Pacific, with a total mileage operated of 437; the Texas and Pacific, with 358; the Kansas City Southern railway, with 222; the Vicksburg, Shreveport, and Pacific, with 170; the Yazoo and Mississippi Valley, with 170; the St Louis, Iron Mountain and Southern railway, with 144.

Newspapers.—In 1900 there were 218 newspapers, including daily, 22; tri-weekly, 1; semi-weekly, 3; weekly, 178; semi-monthly, 4; monthly, 10.

Commerce.—Exports from New Orleans, for year ended 30th June 1900, \$114,702,493; imports, \$17,498,434. Vessels entered and cleared at port of New Orleans, 3097; tonnage, 4,643,064.

Levees.—The revenue by which the levee system is maintained comes from the United States Government, from a state tax of one mill for a general engineer fund, and from revenues from the thirteen levee districts. From 1898 to 1900 the cubic yardage of work done was 18,792,526, the cost of which was \$2,994,957. More than half of the work was done by the United States.

History and Administration.—In 1877 the period of reconstruction ended, owing to the efforts of the White League, and from that time the state has enjoyed a free government and has greatly prospered. In 1890 an attempt was made to renew the charter of the Louisiana State Lottery Company, which offered a large sum annually for the privilege. Governor Nicholls and the Anti-Lottery party resisted the renewal strenuously, but the Bill was passed by the legislature. The United States Government, however, forbade the Lottery Company the use of the mails, and the company withdrew its offer. In 1898 a new constitution was adopted, which superseded that of 1879. Under it the number of representatives in the House may not be more than 116 nor less than 98; and the number of senators not more than 41 nor less than 36. The General Assembly meets every two years on the second Monday of May, and the sessions are limited to sixty days. The governor is elected for four years, and is not again eligible before the expiration of one or more terms. The treasurer is not eligible as his own immediate successor. The judiciary consists of a supreme court of five members appointed for twelve years; of courts of appeal, district courts, and justices of the peace. In New Orleans, besides the courts of appeal and the district courts (civil and criminal), there are city courts and recorder's courts. Lotteries and sales of lottery tickets are prohibited. The leasing or hiring of convicts was prohibited after 1st March 1901. A railway commission of three members is established. The establishment of district schools and district school districts is authorized. No person less than sixty shall vote at any election who shall not have paid a poll-tax for the two preceding years. A code of criminal law ordered by the Constitution has been prepared. A State Board of Charities and Correction has been established to visit institutions and make such suggestions to the governor and legislature as may be necessary. Upon questions submitted to taxpayers women taxpayers have the right to vote, without registration, in person or by their agent. Factories and mines are encouraged by exemption from taxation for ten years from 1st January 1900. As a qualification for voting every citizen must be able to read and write, or must be *bonâ fide* owner of property assessed in the state for not less than \$300. This practically disfranchises the negro, and relieves the state from the unfortunate results of the fifteenth amendment to the National Constitution. An exception is made with regard to the educational or property qualifications in favour of persons who were voters in any state on 1st January 1867, in favour of their sons and grandsons, and of persons who were naturalized prior to 1st January 1898; provided they shall have been residents of the state for five years preceding the date of registration, and shall have registered prior to 1st September 1898. The Australian ballot system is in operation. In 1900 the election for state officers resulted in an overwhelming majority for the Democratic party. An important white Republican party was subsequently formed.

(A. Fo.)

Louisiana, a city of Pike county, Missouri, U.S.A., on the west bank of the Mississippi river, below the mouth of the Salt river, in the eastern part of the state, at an altitude of 458 feet. Its site is on the river banks, and it has a fairly regular plan. It is entered by the Chicago, Burlington and Quincy, and the Chicago and Alton railways. Population (1880), 4325; (1890), 5090; (1900), 5131.

Louisville, the largest and most important city of Kentucky, U.S.A., capital of Jefferson county, in the northern part of the state, on the south bank of the Ohio river at the Falls. The city is regularly laid out, with broad streets, most of which are paved with granite blocks, bricks, cobble-stones, or macadam. It is openly built, with numerous parks, and has a good water supply and sewer system. Three bridges connect it with Jeffersonville and New Albany, on the north bank of the Ohio. The railway development has been remarkable. It is entered by ten railways—the Baltimore and Ohio South-Western; the Chesapeake and Ohio; the Chicago, Indianapolis and Louisville; the Cleveland, Cincinnati, Chicago and St Louis; the Illinois Central; the Louisville and Nashville; the Louisville, Evansville and St Louis Consolidated; the Louisville, Henderson and St Louis; the Pittsburg, Cincinnati, Chicago and St Louis; and the Southern. These, with boats on the Ohio, afford excellent facilities for internal commerce, and give the city a large trade. The manufactures, aided by the enormous water-power supplied by the falls in the Ohio, are of great importance. In 1900 the number of establishments was 2307, with a capital of \$49,344,701, and an average number of 29,926 hands, whose annual wages amounted to \$10,945,720. The cost of materials used was \$41,016,391, and the value of products was \$79,286,390. The products were in great variety, the following being the principal:—men's clothing (factory product and custom work), \$4,710,447; foundry and machine-shop products, \$3,233,222; leather, \$3,114,731; liquors, \$4,691,167; cotton-seed oil and cake, \$4,683,343; slaughtering (wholesale), \$4,771,608; tobacco, cigars, and snuff, \$15,790,366. The total assessed valuation of real and personal property in 1900, on a basis of about 60 per cent. of the full value, was \$121,000,000, the net debt was \$7,755,071, and the rate of taxation \$22.65 per \$1000. The total municipal receipts were \$4,785,744, and the expenditure \$4,459,970. In March 1890 the city was visited by a tornado, which swept across it, killing 76 persons and destroying \$3,000,000 worth of property. Population (1890), 161,129; (1900), 204,731, of whom 21,437 were foreign-born and 39,139 were negroes.

Loulé, a town of Portugal, in the district of Faro, 10 miles north-north-west of Faro. It has a trade in palms, agaves, and esparto grass, and manufactures porcelain and leather. Population (1900), 22,511.

Lourdes, a town, arrondissement of Argèles, department of Hautes-Pyrénées, France, 11 miles, in direct line, west-south-west of Tarbes, on the railway from Toulouse to Bayonne. It is a fortified place of the second class, commanding the defile Gave de Pau. A new quarter of the town has grown up near the famous grotto. It stretches for some distance, and comprises the Church of the Rosary, built in 1885–89, a hospital, convents, hotels, and houses for the accommodation of the numerous visitors resorting to the shrine, said to exceed in number 500,000 a year. Population (1881), 4970; (1901), 8708.

Louth, a municipal borough and market-town in the Louth parliamentary division of Lincolnshire, England, on the Lud, 26 miles east-north-east of Lincoln by rail. A hospital has been erected, also a number of almshouses. The Roman Catholic church has been restored. Area of municipal borough, 2749 acres. Population (1881), 10,691; (1891), 10,040; (1901), 9518.

Louth, a maritime county of Ireland, province of Leinster.

Population.—The area of the administrative county in 1900 was 202,174 acres, of which 82,394 were tillage, 89,398 pasture, 190 fallow, 4524 plantation, 1138 turf bog, 1219 marsh, 12,924 barren

mountain, and 10,387 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, includes the former county of the town of Drogheda. The population in 1881 was 77,684; in 1891, 71,038; and in 1901, 65,741, of whom 32,623 were males and 33,118 females, divided as follows among the different religions:—Roman Catholics, 60,133; Protestant Episcopalians, 4188; Presbyterians, 987; Methodists, 275; and other denominations, 158. The decrease of population between 1881 and 1891 was 8.56 per cent., and between 1891 and 1901, 8.6 per cent. The average number of persons to an acre in 1891 was .35, and of the total population, 44,649 inhabited the rural districts, being an average of 168 persons to each square mile under crops and pasture.

The following table gives the degree of education in 1891, excluding the town of Drogheda, which was then a separate county:—

	Males.	Females.	Total.	Percentage.			
				R. C.	Pr. Ep.	Presb.	Meth.
Read and write	18,106	17,210	35,316	63.6	91.7	92.5	94.7
Read only	3,098	3,567	6,665	13.3	4.5	3.0	2.0
Illiterate	5,548	5,915	11,463	23.1	3.8	4.5	3.3

The percentage of illiterates among Roman Catholics in 1881 was 32.3. In 1891 (including Drogheda) there were 11 superior schools with 622 pupils (Roman Catholics, 426, and Protestants, 196), and 128 primary schools with 11,073 pupils (Roman Catholics, 10,151, and Protestants, 922). The number of pupils on the rolls of the National schools on 30th December 1900 was 9301, of whom 8642 were Roman Catholics and 659 Protestants.

The following table gives the number of births, deaths, and marriages in the years specified:—

Year.	Births.	Deaths.	Marriages.
1881	2252	1715	392
1891	1526	1291	268
1900	1324	1250	269

In 1900 the birth-rate per thousand was 20.1, and the death-rate 19.0; the rate of illegitimacy was 2.6 per cent. of the total births. The total number of emigrants who left the county between 1st May 1857 and 31st December 1900 was 42,682, of whom 20,812 were males and 21,870 females. The chief towns in the county are Dundalk (13,067 in 1901), Drogheda (12,765 in 1901), Ardee (1882 in 1901).

Administration.—The county is divided into two parliamentary divisions, North and South, the number of registered electors in 1901 being respectively 6011 and 5158. The rateable value in 1900 was £244,327. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises two urban and three rural sanitary districts.

Agriculture.—The following tables show the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1900. The figures for 1900 are for the new administrative county.

Year.	Wheat.	Oats.	Barley, Flax, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881	3382	26,544	21,923	11,356	9906	1696	22,582	97,389
1891	1048	24,086	14,344	10,824	8391	1874	23,493	83,560
1895	877	24,864	15,293	10,471	9896	1418	26,170	88,489
1900	655	20,789	15,205	9,881	9332	1638	24,889	82,394

For 1900 the total value of the cereal and other crops was estimated at £508,421. The number of acres under pasture in 1881 was 73,185; in 1891, 89,099; in 1900, 89,398.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	11,044	1549	34,739	83,367	10,471	4841	241,466
1891	10,301	1570	41,520	55,388	19,644	5744	240,779
1895	12,034	1664	46,247	41,085	18,492	5022	259,381
1900	10,688	1632	47,285	50,099	15,967	4737	294,609

The number of milch cows in 1891 was 9507, and in 1900, 10,212. It is estimated that the total value of cattle, sheep, and pigs for 1900 was £734,047, the smallest amount in any Irish county. In 1900 the number of holdings not exceeding 1 acre was 1990; between 1 and 5, 1284; between 5 and 15, 2423; between 15 and 30, 1400; between 30 and 50, 604; between 50 and 100, 481; between 100 and 200, 231; between 200 and 500, 114; and above

500, 12—total, 8539. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901, was 276, amounting to £105,272. The number of loans sanctioned for agricultural improvements under sec. 31 of the Land Act, 1881, between 1882 and 1901 was 80, and the amount issued was £8895. The total amount issued on loan for all classes of works under the Land Improvement Acts from the commencement of operations in 1847 to 31st March 1901 was £48,294.

Fisheries.—The number of vessels registered in the deep-sea and coast fishery district of Dundalk in 1900 was 206, employing 743 hands. The number of persons employed in the salmon fishery districts of Drogheda and Dundalk in the same year was 932.

(W. H. Po.)

Louvain, one of the largest towns of Belgium, in the province of Brabant, 27 miles east of Brussels. It is connected by rail with Brussels, Malines, Liège, and other important centres, and is chiefly noted for its university and its beer. It has considerable breweries, and factories for boots and shoes and clocks. Population (1880), 35,893; (1900), 42,070.

Löwe, Johann Karl Cottfried (1796–1869), German composer, was born at Löbejün, near Halle, 30th November 1796, and was a choir-boy at Köthen from 1807 to 1809, when he went to the Franke Institute at Halle, studying music with Türk. The beauty of Löwe's voice brought him under the notice of Madame de Staël, who procured him a pension from Jérôme Bonaparte, then king of Westphalia; this stopped in 1813, on the flight of the king. He entered the University of Halle as a theological student, but was appointed cantor at Stettin in 1820, and director of the town music in 1821, in which year he married Julie von Jacob, who died in 1823. His second wife, Auguste Lange, was like himself an accomplished singer, and they appeared together in his oratorio performances with great success. He retained his office at Stettin for 46 years, when, after a stroke of paralysis, he was somewhat summarily dismissed. He retired to Kiel, and died 20th April 1869. He undertook many concert tours during his tenure of the post at Stettin, visiting Vienna, London, Sweden, Norway, and Paris. His high soprano voice (he could sing the music of the "Queen of Night" in *Die Zauberflöte* as a boy) had been replaced by a fine tenor. Löwe was a voluminous composer, and wrote five operas, of which only one, *Die drei Wünsche*, was performed at Berlin, in 1834, without much success; seventeen oratorios, many of them for male voices unaccompanied, or with short instrumental interludes only; choral ballads, cantatas, three string quartets, a pianoforte trio; a work for clarinet and piano, published posthumously; and some piano solos. But the branch of his art by which he is now remembered, and in which he must be admitted to have attained perfection, is the solo ballad with pianoforte accompaniment. His treatment of long narrative poems, in a clever mixture of the dramatic and lyrical styles, was undoubtedly modelled on the ballads of Zumsteeg, and has been copied by many composers since his day. They require a cultivated singer to do them justice, but such things as his setting of the "Erlkönig," a very early example; "Archibald Douglas," "Heinrich der Vogler," "Edward," and "Die Verfallene Mühle," belong to the music that must impress every intelligent hearer. The best of these have been sung in England with great success by Henschel, Gura, Bispham, and almost every distinguished concert-singer. (J. A. F. M.)

Lowell, a city of Massachusetts, U.S.A., capital of Middlesex county, at the junction of the Merrimac and Concord rivers, in the north-eastern part of the state. The city is irregularly laid out, and its business streets are paved with granite blocks, while the others are macadamized or gravelled. Its water supply is pumped from the Merrimac. It is divided into nine wards, and it has

railway facilities by branches of the Boston and Maine, and of the New York, New Haven, and Hartford railways. It is one of the chief cities of the country for textile, mainly cotton, manufactures. For this the water power of the Pawtucket Falls in the Merrimac has been utilized, supplemented by steam power. In 1900 the city contained, in all branches of manufacture, 981 establishments, with a total capital of \$46,578,193. These employed an average number of 31,377 hands, and the total product was valued at \$44,774,525. Of these establishments, eight were cotton mills, with a capital of \$21,354,927. In them were employed 13,730 hands, and the product was valued at \$17,038,576, or about 38 per cent. of all manufactured products. The product of woollen and worsted goods was valued at \$4,689,265; of foundry and machine shop products, \$4,258,047; of hosiery and knitted goods, \$3,148,110; and of patent medicines and compounds, \$1,784,338. The assessed valuation of real and personal property in 1900 was \$71,529,515, the net debt was \$3,217,731, and the rate of taxation was \$18.80 per \$1000. Population (1890), 77,696; (1900), 94,969, of whom 40,974 were foreign-born. The death-rate in 1900 was 19.8; in 1890 it was 25.9.

Lowell, James Russell (1819–1891), American author and diplomatist, was born at Elmwood, in Cambridge, Massachusetts, on 22nd February 1819.¹ He was brought up in a neighbourhood bordering on the open country, and from his earliest years he found a companion in nature; he was also early initiated into the reading of poetry and romance, hearing Spenser and Scott in childhood, and introduced to old ballads by his mother. He had for schoolmaster an Englishman who held by the traditions of English schools, so that before he entered Harvard College he had a more familiar acquaintance with Latin verse than fell to the lot of most of his fellows—a familiarity which showed itself later in his mock-pedantic accompaniment to *The Biglow Papers* and his macaronic poetry. He was a wide reader of literature, but a somewhat indifferent student in college, graduating at Harvard without special honours in 1838. During his college course he wrote a number of trivial pieces for a college magazine, and shortly after graduating printed for private circulation the poem which his class asked him to write for their graduation festivities. He was uncertain at first what vocation to choose, and vacillated between business, the ministry, medicine, and law. He decided at last to practise law, and after a course at the Harvard law school, was admitted to the bar. While studying for his profession, however, he continued the pursuit of literature in a random fashion, contributing poems and prose articles to various magazines. At this period he was in a somewhat wayward mood, conscious of a latent power, deeply enamoured of letters, a student of the art of literature, but uncertain just how to direct his impulses. He cared little for the

¹ The ancestry of James Russell Lowell was of mingled English and Scottish strain. On his father's side he was descended from Percival Lowell or Lowle, who emigrated from Somersetshire, England, in 1639, to Massachusetts Bay. The descendants of Percival remained in Boston and its vicinity down to James Russell, and contained among them more than one man of note. John Lowell, the grandfather of James Russell, was a judge of the federal court appointed by Washington, and took a conspicuous part in the framing of the Massachusetts constitution; and Charles Lowell, the father, was long honoured as a minister in Boston; Francis Cabot Lowell, an uncle of James Russell, was the organizer of the industries on the banks of the Merrimac which resulted in the building of the city of Lowell, and a son of Francis Cabot was the founder of the Lowell Institute, a centre of diffusing light in Boston. On his mother's side Lowell was descended from the Spences and Traills, who made their home in the Orkney Isles, his great-grandfather, Robert Traill, returning to England upon the breaking out of hostilities in 1775.

profession of law, regarding it simply as a distasteful means of livelihood, yet his experiments in writing could not greatly encourage him to trust to this for support. An unhappy adventure in love deepened his sense of failure, but a new and profound experience suddenly steadied his purpose, and helped besides to fashion and guide certain vague tendencies which he felt towards the reform movements then stirring in the society about him. He became betrothed to Maria White in the autumn of 1840, and the next twelve years of his life were deeply affected by her influence. She was herself a poet of delicate power, but she was also possessed of a lofty enthusiasm, a high conception of purity and justice, and of a practical temper which led her to concern herself actively in the movements directed against the evils of intemperance and slavery. Lowell was already looked upon by his companions as a man marked by wit and poetic sentiment; Miss White was admired for her beauty, her character, and her intellectual gifts, and the two became thus the hero and heroine among a group of ardent young men and women, who set them upon a dais, as it were, and bestowed their homage. The first-fruits of this passion was a volume of poems, published in 1841, entitled *A Year's Life*, which was inscribed by Lowell in a veiled dedication to his future wife, and was a record of his emotions under this new experience, with a backward glance at the preceding period of depression and irresolution. The betrothal, moreover, stimulated Lowell to new efforts towards self-support, and though nominally maintaining his law office, he threw his energy into the establishment, in company with a friend, Robert Carter, of a literary journal, to which the young men gave the name of *The Pioneer*. It was to open the way to new ideals in literature and art, and the writers to whom Lowell turned for assistance—Hawthorne, Emerson, Whittier, Poe, Story, and Parsons, none of them yet possessed of a wide reputation—indicate the acumen of the editor. Lowell himself had already turned his studies in dramatic and early poetic literature to account in another magazine, and continued the series in *The Pioneer*, besides contributing poems; but after the issue of three monthly numbers, beginning in January 1843, the magazine came to an end, partly because of a sudden disaster which befell Lowell's eyes, partly through the inexperience of the conductors and unfortunate business connexions.

The venture confirmed Lowell in his bent towards literature. At the close of 1843 he published a collection of his poems, and a year later he gathered up certain material which he had printed, sifted and added to it, and produced *Conversations on some of the Old Poets*. The dialogue form was used merely to secure an undress manner of approach to his subject; there was no attempt at the dramatic. The book reflects curiously Lowell's mind at this time, for the conversations relate only partly to the poets and dramatists of the Elizabethan period; a slight suggestion sends the interlocutors off on the discussion of current reforms in church and state and society. Literature and reform were dividing the author's mind, and continued to do so for the next decade. Just as this book appeared Lowell and Miss White were married, and spent the winter and early spring of 1845 in Philadelphia. Here, besides continuing his literary contributions to magazines, Lowell had a regular engagement as an editorial writer on *The Pennsylvania Freeman*, a fortnightly journal devoted to the Anti-Slavery cause. In the spring of 1845 the Lowells returned to Cambridge and made their home at Elmwood. On the last day of the year their first child, Blanche, was born, but she lived only fifteen months. A second daughter, Mabel, was born six months after Blanche's death, and lived to survive her

father; a third, Rose, died an infant. Lowell's mother meanwhile was living, sometimes at home, sometimes at a neighbouring hospital, with clouded mind, and his wife was in frail health. These family troubles and the tie of a narrow income conspired to make Lowell almost a recluse in these days, but from the retirement of Elmwood he sent forth writings which show how large an interest he took in affairs. He contributed poems to the daily press, called out by the Slavery question; he was, early in 1846, a correspondent of the London *Daily News*, and in the spring of 1848 he formed a connexion with the *National Anti-Slavery Standard* of New York, by which he agreed to furnish weekly either a poem or a prose article. The poems were most frequently works of art, occasionally they were tracts; but the prose was almost exclusively concerned with the public men and questions of the day, and forms a series of incisive, witty, and sometimes prophetic diatribes. It was a period with him of great mental activity, and is represented by four of his books which stand as admirable witnesses to the Lowell of 1848, namely, the second series of *Poems*, containing among others "Columbus," "An Indian Summer Reverie," "To the Dandelion," "The Changingling"; *A Fable for Critics*, in which, after the manner of Leigh Hunt's *The Feast of the Poets*, he characterizes in witty verse and with good-natured satire American contemporary writers, and in which, the publication being anonymous, he included himself; *The Vision of Sir Launfal*, a romantic story suggested by the Arthurian legends—one of his most popular poems; and finally *The Biglow Papers*.

Lowell had acquired a reputation among men of letters and a cultivated class of readers, but this satire at once brought him a wider fame. The book was not premeditated; a single poem, called out by the recruiting for the abhorred Mexican war, couched in rustic phrase, and sent to the *Boston Courier*, had the inspiriting dash and electrifying rat-tat-tat of this new recruiting-sergeant in the little army of Anti-Slavery reformers. Lowell himself discovered what he had done at the same time that the public did, and he followed the poem with eight others either in the *Courier* or the *Anti-Slavery Standard*. He developed four well-defined characters in the process—a country farmer, Ezekiel Biglow, and his son Hosea; the Rev. Homer Wilbur, a shrewd old-fashioned country minister; and Birdofredum Sawin, a Northern renegade who enters the army, together with one or two subordinate characters; and his stinging satire and sly humour are so set forth in the vernacular of New England, as to give at once a historic dignity to this form of speech. (Later he wrote an elaborate paper to show the survival in New England of the English of the early 17th century.) He embroidered his verse with an entertaining apparatus of notes and mock criticism. Even his index was spiced with wit. The book, a caustic arraignment of the course taken in connexion with the annexation of Texas and the

war with Mexico, made a strong impression, and the political philosophy secreted in its lines became a part of household literature. It is curious to observe how repeatedly this arsenal was drawn upon in the discussions in America about the "Imperialistic" developments of 1900. The death of Lowell's mother, and the fragility of his wife's health, led Lowell, with his wife, their daughter Mabel, and their infant son Walter, to go to Europe in 1851, and they went direct to Italy. The early months of their stay were saddened by the death of Walter in Rome, and by the news of the illness of Lowell's father, who had a slight shock of paralysis. They returned in November 1852, and Lowell published some recollections of his journey in the magazines, collecting the sketches later in a prose volume, *Fireside Travels*. He took some part also in the editing of an American edition of the *British Poets*, but the low state

of his wife's health kept him in an uneasy condition, and when her death (27th October 1853) released him from the strain of anxiety, there came with the grief a readjustment of his nature and a new intellectual activity. At the invitation of his cousin, he delivered a course of lectures on English poets before the Lowell Institute in Boston in the winter of 1855. This first formal appearance as a critic and historian of literature at once gave him a new standing in the community, and was the occasion of his election to the Smith Professorship of Modern Language in Harvard College, then vacant by the retirement of Longfellow. Lowell accepted the appointment, with the proviso that he should have a year of study abroad. He spent his time mainly in Germany, visiting Italy, and

JAMES RUSSELL LOWELL.
(From a photograph by Elliott and Fry, London.)

increasing his acquaintance with the French, German, Italian, and Spanish tongues. He returned to America in the summer of 1856, and entered upon his college duties, retaining his position for twenty years. As a teacher he proved himself a quickener of thought amongst students, rather than a close and special instructor. His power lay in the interpretation of literature rather than in linguistic study, and his influence over his pupils was exercised by his own fireside as well as in the relation, always friendly and familiar, which he held to them in the classroom. In 1856 he married Miss Frances Dunlap, a lady who had since his wife's death had charge of his daughter Mabel.

In the autumn of 1857 *The Atlantic Monthly* was established, and Lowell was its first editor. He at once gave the magazine the stamp of high literature and of bold speech on public affairs. He held this position only till the spring of 1861, but he continued to make the magazine the vehicle of his poetry and of some prose for the rest of his life; his prose, however, was more abundantly presented in the pages of *The North American Review* during the years 1862-72, when he was associated with Mr Charles Eliot Norton in its conduct. This magazine especially gave him the opportunity of expression of political views during the eventful years of the War of

the Union. It was in *The Atlantic* during the same period that he published a second series of *The Biglow Papers*. Both his collegiate and editorial duties stimulated his critical powers, and the publication in the two magazines, followed by republication in book form, of a series of studies of great authors, gave him an important place as a critic. Shakespeare, Dryden, Lessing, Rousseau, Dante, Spenser, Wordsworth, Milton, Keats, Carlyle, Thoreau, Swinburne, Chaucer, Emerson, Pope, Gray—these are the principal subjects of his prose, and the range of topics indicates the catholicity of his taste. He wrote also a number of essays, such as "My Garden Acquaintance," "A Good Word for Winter," "On a Certain Condescension in Foreigners," which were incursions into the field of nature and society. Although the great bulk of his writing was now in prose, he made after this date some of his most notable ventures in poetry. In 1868 he issued the next collection in *Under the Willows and other Poems*, but in 1865 he had delivered his "Ode recited at the Harvard Commemoration," and the successive Centennial historical anniversaries drew from him a series of stately odes.

In 1877 Lowell, who had mingled so little in party politics that the sole public office he had held was the nominal one of elector in the Presidential election of 1876, was appointed by President Hayes minister resident at the court of Spain. He had a good knowledge of Spanish language and literature, and his long-continued studies in history and his quick judgment enabled him speedily to adjust himself to these new relations. Some of his despatches to the home government were published in a posthumous volume—*Impressions of Spain*. In 1880 he was transferred to London as American minister, and remained there till the close of President Arthur's administration in the spring of 1885. As a man of letters he was already well known in England, and he was in much demand as an orator on public occasions, especially of a literary nature; but he also proved himself a sagacious publicist, and made himself a wise interpreter of each country to the other. Shortly after his retirement from public life he published *Democracy and other Addresses*, all of which had been delivered in England. The title address was an epigrammatic confession of political faith as hopeful as it was wise and keen. The close of his stay in England was saddened by the death of his second wife in 1885. After his return to America he made several visits to England. His public life had made him more of a figure in the world; he was decorated with the highest honours Harvard could pay officially, and with degrees of Oxford, Cambridge, St Andrews, Edinburgh, and Bologna. He issued another collection of his poems, *Heartsease and Rue*, in 1888, and occupied himself with revising and rearranging his works, which were published in ten volumes in 1890. The last months of his life were attended by illness, and he died at Elmwood on 12th August 1891. After his death his literary executor, Charles Eliot Norton, published a brief collection of his poems, and two volumes of added prose, besides editing his letters.

The spontaneity of Lowell's nature is delightfully disclosed in his personal letters. They are often brilliant, and sometimes very penetrating in their judgment of men and books; but the most constant element is a pervasive humour, and this humour, by turns playful and sentimental, is largely characteristic of his poetry, which sprang from a genial temper, quick in its sympathy with nature and humanity. The literary refinement which marks his essays in prose is not conspicuous in his verse, which is of a more simple character. There was an apparent conflict in him of the critic and the creator, but the conflict was

superficial. The man behind both critical and creative work was so genuine, that through his writings, and speech, and action he impressed himself deeply upon his generation in America, especially upon the thoughtful and scholarly class who looked upon him as especially their representative. This is not to say that he was a man of narrow sympathies. On the contrary, he was democratic in his thought, and outspoken in his rebuke of whatever seemed to him antagonistic to the highest freedom. Thus, without taking a very active part in political life, he was recognized as one of the leaders of independent political thought. He found expression in so many ways, and was apparently so inexhaustible in his resources, that his very versatility and the ease with which he gave expression to his thought sometimes stood in the way of a recognition of his large, simple political idealism and the singleness of his moral sight.

WRITINGS.—The *Works of James Russell Lowell*, in ten volumes (Boston and New York, Houghton, Mifflin, and Co.), 1890; latest *Literary Essays and Addresses*, 1891; *The Old English Dramatists*, 1892; *Conversations on some of the Old Poets* (Philadelphia, David M'Kay) (reprint of the volume published in 1843, and subsequently abandoned by its author), 1893; *The Power of Sound: a Rhymed Lecture* (New York, privately printed), 1896; *Lectures on English Poets* (Cleveland, The Rowfant Club), 1899.

MEMOIRS.—*Letters of James Russell Lowell*, edited by CHARLES ELIOT NORTON, in two volumes (New York, Harper and Brothers), 1899.—*Life of James Russell Lowell*, by HORACE E. SCUDDER (Houghton, Mifflin, and Co.), 1901. (H. E. S*.)

Löwenberg, a town of the province of Silesia, Prussia, 39 miles east of Görlitz by rail. It is one of the oldest towns in Silesia, its town hall dating from the 16th century, and a Roman Catholic church from the 13th century (restored in 1862). In the town park there is a marble bust of Blücher (1841) by Rauch, and a monument of the war of 1813 has been erected near by. There are sandstone and gypsum quarries, linen, cotton, and woollen mills, and cultivation of fruit and vegetables. Population (1901), 5293.

Lówestoft, a watering-place, seaport, and municipal borough in the Lowestoft parliamentary division of Suffolk, England, 23 miles south-west of Norwich by rail. In 1885 the town was incorporated, and it is now governed by a mayor, 8 aldermen, and 24 councillors. Technical schools have been built, the town is provided with electric light, and it is proposed to lay down municipal electric tramways. The new town, or South Lowestoft, has an esplanade which, joining the south pier of the harbour, forms a long promenade. The trawl basin was extended in 1892, nearly doubling its size. About 600 smacks and fishing boats belong to the port. Altogether the harbour has between 6000 and 7000 feet of wharfage, and an area of about 50 acres, and the depth is 15–16 feet. The total value of the imports of foreign and colonial merchandise in 1900 was £148,883; of exports, £150,569. The port was entered and cleared by an aggregate of 1577 vessels of 226,079 tons in 1900. Population of municipal borough (2306 acres) (1881), 19,702; (1891), 23,347; (1901), 29,842.

Lozère, a department of the south-east of France, traversed by the Cévennes Mountains and watered by the Lot, the Tara, and the Allier.

Area, 1996 square miles. The population, 141,264 in 1886, had decreased to 124,049 in 1901. Births in 1899, 3438, of which 154 were illegitimate; deaths, 2690; marriages, 839. There were in 1896, 848 schools, with 29,000 pupils, the illiterate constituting 3 per cent. of the population. Out of 1,361,600 acres of cultivated land in 1896, 387,960 acres constituted all the plough-land, the rest of the department being almost all occupied by mountain pastures. The wheat crop of 1899 was valued at only £64,000; meslin, £32,000; rye, £172,000; the other cereals at much smaller

values. The produce of the natural pastures and grass lands amounted in 1899 to the value of £312,000. The industrial crops (colza, rape, flax, &c.) make no figure in the official returns of 1899. The production of chestnuts, however, was valued at £41,000. Though in the returns of 1899 the production of mulberry leaves is left blank, yet the same year is credited with the production of 1685 cwts. of silk-worm cocoons. The live stock included in 1899, 317,670 sheep, 71,610 cattle, and 30,030 pigs, but domestic animals of other species were poorly represented. Mining in 1898 produced 900 tons of iron and 2600 tons of lead, while the metallurgic production reached a value of £1200. The industries are in a backward state. Mende, the capital, had, in 1901, 7319 inhabitants.

Luang Prabang, capital of the Lao state of that name, situated on the Me Kong river in 19° 54' N. and 102° 9' E. It nestles round the pagoda hill which rises about 200 feet above the plain on the promontory of land round which the Nam Kan winds to the main river. It has a population of about 9000 people. In 1887 it was taken and sacked by the Haw or Black Flags. In 1893 Siam was compelled to renounce her claims to the whole left bank of the Me Kong, including Luang Prabang and the magnificent highlands of Chieng Kwang, which thus now form part of the French Indo-Chinese possessions. That portion of the state which was on the right bank of the Me Kong was not affected by the treaty, except in so far as a portion of it fell within the sixteen miles' zone within which Siam agreed not to keep troops. What trade there is, is in the hands of a few Chinese or Sham traders; hill rice and other jungle products are imported from the surrounding districts by the Ka or hill people. The exports, which include gum benjamin, silk, wax, sticklac, cutch, cardamom, a little ebony, cinnamon, indigo, rhinoceros and deer horns, ivory, and fish roe, formerly all passed by way of Paklai to the Me Nam, and so to Bangkok, but have now almost entirely ceased to follow that route, the object of the French Government being to deflect the trade through French territory. The whole annual trade of the district does not probably exceed £80,000 in value. (See LAOS.)

Lubao, a town in the south-western portion of the province of Pampanga, Luzon, Philippine Islands. It lies in a low, fertile, and extensive plain, which is especially suited to the growing of sugar. Many of its inhabitants occupy themselves in the neighbouring nipa swamps, either preparing the nipa leaves for use in house construction, or distilling alcohol from the juice secured by tapping the blossom stalks. Lubao has good water communication with Manila by means of tidal streams and Manila Bay, so that its products are readily marketed. The language is Pampangan. Population, 21,000.

Lübben, a town of Prussia, province of Brandenburg, on the Spree, 47 miles by rail south-south-east of Berlin. It is the chief town of the Spreewald, and has saw-mills, shoe factories, &c., and is famous for its *gurken*, or small pickling cucumbers. Population (1900), 6818.

Lübeck, a state and city of the German empire, situated on an arm of the Baltic Sea, between Mecklenburg and Holstein. (1) The city stands on the river Trave, 10 miles above its entrance into the Bay of Lübeck. In spite of the tendency to modernize its streets and private houses, Lübeck, owing to its churches, town hall (restored), and one or two other public buildings, still preserves something of the character of a mediæval town. The entrance hall of the Hospital of the Holy Ghost is a 13th-century chapel, restored in 1866, and painted by Olbers in 1898. Of modern buildings and institutions the most noteworthy are the law courts (1895), the Roman Catholic church (1889-91), the (Gothic) museum (1892), the synagogue (1880), the imperial post office (1885), the gymnasium (1891), the commercial institute, technical

school, school of navigation, teachers' seminary, deaf and dumb asylum, lunatic asylum, zoological gardens, a statue of the poet Geibel (1889), and a fountain (1875) commemorative of the war of 1870-71. Geibel (1815-1884), like the painter Overbeck (1789-1869), was a native of Lübeck. This city is famous for the number as well as wealth of its charitable institutions. Its prosperity depends, and has always depended, principally upon its commerce. But its position as the first German emporium of the west end of the Baltic is being to some extent impaired by Hamburg and Bremen since the construction of the North Sea and Baltic Canal, and by the rapid growth and enterprise of Stettin. In order to counter-balance their rivalry, at all events to some extent, the quays have been extended, a canal (opened in 1900) has been constructed to connect the Trave with the Elbe, the river up to the wharves has been deepened to 25 feet or more (begun in 1900), and the harbour generally has been improved and enlarged. The river is kept open in winter by powerful ice-breakers. A new harbour was made in 1899-1900 on the Wakenitz Canal for boats engaged in inland traffic, more especially on the Elbe and Elbe-Trave Canal. Also, a new railway station is under construction on the right bank of the Trave, near the entrance to the port. Lübeck trades principally with Denmark, Sweden, Finland, Russia, the eastern provinces of Prussia, Great Britain, and the United States. The imports have increased in annual value from £9,721,700 in 1875 to £12,917,500 in 1895 and to £16,327,000 in 1899. The exports have likewise increased, namely, from £8,015,700 in 1875 to £10,553,000 in 1895 and to £12,975,000 in 1899. The number of vessels which entered the port increased from 2301 of 311,457 tons in 1880, to 2316 of 486,820 tons in 1895 and to 2820 of 556,550 tons in 1900. In this last year the merchant fleet numbered 25 vessels of 8830 tons. The industries are steadily growing in importance, the chief being breweries and distilleries, saw-mills and planing-mills, shipbuilding, fish-curing, the manufacture of machinery, engines, bricks, resin, preserves, enamelled and tin goods, cigars, furniture, soap, and leather. Population (1885), 55,399; (1895), 69,874; (1900), 82,098.

(2) The FREE STATE (area, 115 square miles) embraces the city of Lübeck, the town of Travemünde (population, 1800), and various villages, situated partly around and between these two, and partly as exclaves in Lauenburg and Holstein, the total population being 83,324 in 1895 and 96,775 in 1900, of whom 47,784 were males and 48,991 females. The people are nearly all (97.5 per cent.) of the Lutheran faith. The state income was £296,500 in 1900-1, and the expenditure £311,000. About one-half of the income is derived from direct and indirect taxes, and the other half from domain lands, from interests and dividends, and from contributions from Imperial taxes and customs (Lübeck joined the Zollverein in 1868). The state debt amounted in 1900 to £1,617,300. In 1900 the state's contribution to the empire amounted to £41,965. Lübeck has one vote in the Federal Council of the empire, and sends one representative to the Imperial Diet. In 1900 the state possessed 4003 horses, 8542 cattle, 10,485 pigs, and 3175 sheep. Hay, potatoes, oats, rye, and wheat are the principal crops cultivated. The breweries in 1899 produced 2,706,000 gallons of beer.

(J. T. BE.)

Lublin, a province of Russian Poland, bounded on the north by Siedlce, on the east by Volhynia, on the south by Galicia, and on the west by Radom. Area, 6499 square miles. The surface is an undulating plain, built up of Cretaceous deposits, 800 to 900 feet in altitude, and reaching in one place 1050 feet; it is covered with thick forests of oak, beech, and lime, is intersected by countless ravines, and is thinly inhabited. A wide marshy lowland spreads between the Vistula and the Wieprz. It is drained by the Vistula in the west and by the Bug along its eastern frontier, as well as by their tributaries—Wieprz, San, Tanew, and Kushva. Parts of the

province, being covered with black earth, are very fertile, but other parts are sandy. Owing to this fertility and the vicinity of good markets, agriculture is in a good condition and improving. Many Germans settled in the province before immigration was stopped by the law of 1887.

Nearly one-third of the total area is under forests; meadows and pastures cover nearly 320,000 acres, and the remainder is under the plough. Rye, oats, wheat, and potatoes are the chief crops, rye and wheat being considerable items of export. Flax, hemp, and beetroot are also cultivated. There were in 1894, 194,191 horses, 377,465 horned cattle, and 368,827 sheep, of which a great number were of finer breeds. In 1897 the population was 1,201,549, of whom 604,886 were women. The Greek Orthodox (chiefly Little Russians in the south-east) numbered 241,523, Roman Catholics (*i.e.*, Poles), 754,693; Jews, 170,541; Protestants, 33,669; and Baptists, 1086. The urban population was 148,196 in 1897. There were 34,107 military. The factories and other industrial establishments, 1538 in number, employ about 7000 workers, and consist chiefly of distilleries, sugar-works, steam flour-mills, tanneries, saw-mills, and factories of bent-wood furniture. Domestic industries are widely developed in the villages. The navigation of the rivers occupies a considerable portion of the population. There were in 1895, 610 schools, in which 30,183 children (7879 girls) received education, there being one school for every 1954, and one pupil for every 40 inhabitants. There was an agricultural institute at Nowa-Alexandrya, 1 seminary for teachers, 1 theological seminary, 6 gymnasia, 482 primary schools, and 105 Jewish *heders*. The government is divided into nine districts, the chief towns of which are Lublin, capital of the province (50,152 inhabitants in 1897); Bilgoray (6286); Chełm (19,236, with archaeological museum); Hrubieszow (10,699); Janów (7927); Krasnystaw (8879); Lubartow (5249); Nowa-Alexandrya or Puławy (3892); and Tomaszów (21,041).

(P. A. K.)

Lubny, a district town of Russia, government of Poltava, 14 miles from the Romodan station of the Kharkov-Nikolaev railway. It is a very old town, being mentioned in 1107. Almost from its foundation gardening has been a favourite occupation of the inhabitants, and Peter I. founded here a botanic garden for the cultivation of medical plants. Gardening and the preparation of jam, dried and pickled vegetables, &c., are carried on as a trade. The town has a meteorological observatory, two gymnasia, a lower agricultural school, &c., and has lately been growing. Population (1897), 10,108, or 12,445 with the suburbs.

Lubrication.—Our knowledge of the action of oils and other viscous fluids in diminishing friction and wear between solid surfaces has within recent years undergone a complete revolution, and from being purely empirical has become a connected theory, based on the known properties of matter, subjected to the definition of mathematical analysis and verified by experiment. The theory was published in 1886 (*Phil. Trans. Roy. Soc.*, 1886, pt. i. pp. 157-234); but it is the purpose of this article not so much to explain its application, as to give a brief account of the introduction of the misconceptions that so long prevailed, and of the manner in which their removal led to its general acceptance.

A revolution of ideas in physical science can result only from some discrepancy between the actual results observed, in certain circumstances, and the conclusions arrived at for the same circumstances by means of geometrical and physical analyses. Such discrepancies are evidence that some circumstance has been left out of account in the previous analyses, and indicate the need for an extension of the theory, though they do not, of necessity, furnish any clue to the particular circumstance omitted or indicate the character of the extension required. The circumstance, in respect of friction and lubrication, of which account was only taken after the year 1883, is altogether singular in the history of physics, since up to that year no one had any idea that our knowledge was other than purely empirical, involving no theoretical analysis, and

hence subject to no discrepancy. Friction, or resistance to tangential shifting of matter over matter, whatever the mode and arrangement, differs greatly according to the materials, but, like all material resistance, is essentially limited. The range of the limits in available materials has a primary place in determining mechanical possibilities, and from the earliest times they have demanded the closest attention on the part of all who have to do with structures or with machines, the former being concerned to find those materials and their arrangements which possess the highest limits, and the latter the materials in which the limits are least. Long before the reformation of science in the 15th and 16th centuries both these limits had formed the subject of such empirical research as disclosed numerous definite although disconnected circumstances under which they could be secured; and these, however far from the highest and lowest, satisfied the exigencies of practical mechanics at the time, thus initiating the method of extending knowledge which was to be subsequently recognized as the only basis of physical philosophy. In this purely empirical research the conclusion arrived at represented the results for the actual circumstance from which they were drawn, and thus afforded no place for theoretical discrepancies. However, in the attempts at generalization which followed the reformation of science, opportunity was afforded for such discrepancies in the mere enunciation of the circumstances in which the so-called laws of friction of motion are supposed to apply. The circumstances in which the great amount of empirical research was conducted as to the resistance between the clean, plane, smooth surfaces of rigid bodies moving over each other under pressure, invariably include the presence of air at atmospheric pressure around, and to some extent between, the surfaces; but this fact had received no notice in the enunciation of these laws, and this constitutes a theoretical departure from the conditions under which the experience had been obtained. Also, the theoretical division of the law of frictional resistance into two laws—one dealing with the limit of rest, and the other asserting that the friction of motion, which is invariably less in similar circumstances than that of rest, is independent of the velocity of sliding—involves the theoretical assumption that there is no asymptotic law of diminution of the resistance, since, starting from rest, the rate of sliding increases. The theoretical substitution of ideal rigid bodies with geometrically regular surfaces, sliding in contact under pressure at the common regular surface, for the aerated surfaces in the actual circumstances, and the theoretical substitution of the absolute independence of the resistance of the rate of sliding for the limited independence in the actual circumstances, prove the general acceptance of the conceptions—(1) That matter can slide over matter under pressure at a geometrically regular surface; (2) That, however much the resistance to sliding under any particular pressure (the coefficient of friction) may depend on the physical properties of the materials, the sliding under pressure takes place at the geometrically regular surface of contact of the rigid bodies; and (3) as the consequence of (1) and (2), That whatever the effect of a lubricant, such as oil, might have, it could be a physical surface effect. Thus not only have these general theoretical conceptions, resulting from the theoretical laws of friction, failed to afford any indication that the lubricant may diminish the resistance by the mere mechanical separation of the surfaces, but they have absolutely precluded the idea that such might be the case. The result was that, notwithstanding the soundness of the method employed in the early start, and the continued efforts demanded by practical mechanics, all subsequent attempts to reduce the empirical facts, where a lubricant was used, to such general laws as might reveal the separate

functions of the somewhat complex circumstances on which lubrication depends, and so afford guidance for further extension, completely failed. Thus in the early part of the year 1883 the science of lubrication had not advanced beyond the empirical stage.

This period of stagnation was terminated by an accidental phenomenon observed by Mr Beauchamp Tower, while engaged on his memorable research on the friction of the "journals" of railway carriages. His observation led him to a line of experiments which afforded conclusive evidence that in these experiments the general function of the lubricant was the mechanical separation of the metal surfaces by a layer of fluid of finite thickness, thus upsetting once for all the preconceived ideas as expressed in the laws of the friction of motion. On the publication of Mr Tower's reports (*Proc. Inst. M. E.*, November 1883), it was at once recognized by several physicists (*B. A. Report*, 1884, pp. 14, 625) that the evidence they contained afforded a rational basis for further study of the actions involved, indicating, as it does in no uncertain manner, the circumstances—namely, the properties of viscosity and cohesion possessed by fluids—account of which had not been taken in the previous theoretical conclusions. When this was recognized it also became apparent that continuous or steady lubrication, such as that of Mr Tower's experiments, is only secured when the solid surfaces separated by the lubricant are so shaped that the thickness at the ingoing side is greater than that at the outgoing side. With respect to what has already been said of the singular obscurity of the circumstances which were overlooked in the laws of friction, it is important to notice that the accidental circumstances which produced the phenomenon observed by Mr Tower are such as in all probability had never occurred before, so that their subsequent recurrence was equally improbable. Moreover, up to the present time these circumstances are unique in respect of the evidence they afford as to the mechanical action of the lubricant, the thickness of the film of which, although finite, is much too small to admit of direct measurement.

Thus it was the discovery by Mr Tower that the lubricant separated the solid surfaces, which put an end to the period of stagnation; while the appreciation of the significance of this discovery, which immediately followed, was the result of the preparation of the ground by the study of the properties of resistance possessed by all fluids to rates of distortional motion. The analyses of the viscous properties of fluids, and of the motions of fluids, when these viscous resistances are taken into account, have exercised the highest powers of mathematicians, even when no boundaries had to be considered. When the general equations of viscous fluids had, as the result of the labours of Navier (1822),¹ Cauchy,² Poisson,³ St Venant,⁴ and in 1845 of Sir G. Gabriel Stokes,⁵ been shown to involve no other assumption than that the stresses, other than the pressure equal in all directions, are linear functions of the distortional rates of strain multiplied by a constant coefficient, it was found that the only solutions of which the equations admitted, when applied to fluids flowing between fixed boundaries, as water in a pipe, were singular solutions for steady or steady periodic motion, and that the conclusions they entailed, that the resistance would be proportional to the velocity, were for the most part directly at variance with the common experience that the resistances varied with the square of the velocity. This discrepancy was sometimes supposed to be the result

of eddies in the fluid, but it was not till the year 1883 that it was discovered by experiments with colour bands that, in the case of geometrically similar boundaries the existence or non-existence of such eddies depended upon a definite relation between the mean velocity (U) of the fluid, the distance between the boundaries, and the ratio of the coefficient of viscosity to the density (μ/ρ), expressed by $UD\rho/\mu=K$, where K is a physical constant independent of units, which has a value between 1900 and 2000, and for parallel boundaries D is four times the area of the channel divided by the perimeter of the section (*Phil. Trans. R. S.* part iii., 1883, pp. 935–982). K is thus a criterion at which the law of resistance to the mean flow changes suddenly (as U increases), from being proportional to the flow, to a law involving higher powers of the velocity at first, but as the rates increase approaching an asymptote in which the power is a little less than the square.

This sudden change in the law of resistance to the flow of fluid between solid boundaries, depending as it does on a complete change in the manner of the flow—from direct parallel flow to sinuous eddying motion—serves to determine analytically the circumstances as to the velocity and the thickness of the film under which any fluid having a particular coefficient of viscosity can act the part of a lubricant. For as long as the circumstances are such that $UD\rho/\mu$ is less than K , the parallel flow is held stable by the viscosity, so that only one solution is possible—that in which the resistance is the product of μ multiplied by the rate of distortion, as $\mu \frac{du}{dy}$; in this case the fluid

has lubricating properties. But when the circumstances are such that $UD\rho/\mu$ is greater than K , other solutions become possible, and the parallel flow becomes unstable, breaks down into eddying motion, and the resistance varies as ρu^2 , which approximates to $\rho u^{1.78}$ as the velocity increases; in this state the fluid has no lubricating properties. Thus, within the limits of the criterion, the rate of displacement of the momentum of the fluid is insignificant as compared with the viscous resistance, and may be neglected; while outside this limit the direct effects of the eddying motion completely dominate the viscous resistance, which in its turn may be neglected. Thus K is a criterion which separates the flow of fluid between solid surfaces as definitely as the flow of fluid is separated from the relative motions in elastic solids, and it is by the knowledge of the limit on which this distinction depends that the theory of viscous flow can with assurance be applied to the circumstance of lubrication.

Until the existence of this physical constant was discovered, any theoretical conclusions as to whether in any particular circumstances the resistance of the lubricant would follow the law of viscous flow or that of eddying motion was impossible. Thus Mr Tower, being unaware of the discovery of the criterion, which was published in the same year as his reports, was completely thrown off the scent in his endeavour to verify the evidence he had obtained as to the finite thickness of the film by varying the velocity. He remarks in his first report that, "according to the theory of fluid motion, the resistance would be as the square of the velocity, whereas in his results it did not increase according to this law." That such a discrepancy, had it not been immediately removed by the recognition of the existence of the criterion, must still have obscured the subject, affords a proof that Mr Tower's discovery occurred at the earliest time that physical science was ready for its full appreciation. The rational theory of lubrication does not, however, depend solely on the viscosity within the interior of fluids, but also depends on the surface action between the

fluid and the solid. In many respects the surface actions, as indicated by surface tension, are still obscure, and there has been a very general tendency to assume that there may be discontinuity in the velocity at the common surface. But whatever these actions may be in other respects, there is abundant evidence that there is no appreciable discontinuity in the velocity at the surfaces as long as the fluid has finite thickness. Hence in the case of lubrication the velocities of the fluid at the surfaces of the solids are those of the solid. In as far as the presence of the lubricant is necessary, such properties as cause oil in spite of its surface tension to spread even against gravity over a bright metal surface, while mercury will concentrate into globules on the bright surface of iron, have certainly an important place in securing lubrication where the action is intermittent, as in the escapement of a clock. If there is oil on the pallet, although the pressure of the tooth causes this to flow out laterally from between the surfaces, it goes back again by surface tension during the intervals; hence the importance of using fluids with low surface tension like oil, or special oils, when there is no other means of securing the presence of the lubricant.

The differential equations for the equilibrium of the lubricant are what the differential equations of viscous fluid in steady motion become when subject to the conditions necessary for lubrication as already defined—(1) The velocity is below the critical value; (2) At the surfaces the velocity of the fluid is that of the solid; (3) The thickness of the film is small compared with the lateral dimensions of the surfaces and the radii of curvature of the surfaces. By the first of these conditions all the terms having ρ as a factor may be neglected, and the equations thus become the equations of equilibrium of the fluid; as such, they are applicable to fluid whether incompressible or elastic, and however the pressure may affect the viscosity. But the analysis is greatly simplified by omitting all terms depending on compressibility, and by taking μ constant; this may be done without loss of generality in a qualitative sense. With these limitations we have for the differential equation of the equilibrium of the lubricant:—

$$\left. \begin{aligned} 0 &= \frac{dp}{dx} - \mu \nabla^2 u, \text{ \&c.}, \text{ \&c.}, \quad 0 = \frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} \\ 0 &= p_{yx} - \mu \left(\frac{du}{dy} + \frac{dv}{dx} \right), \text{ \&c.}, \text{ \&c.} \end{aligned} \right\} \quad (1)$$

These are subject to the boundary conditions (2) and (3). Taking x as measured parallel to one of the surfaces in the direction of relative motion, y normal to the surface, and z normal to the plane of xy by condition (3), we may without error disregard the effect of any curvature in the surfaces. Also v is small compared with u and w , and the variations of u and w in the directions x and z are small compared with their variation in the direction y . The equations (1) reduce to

$$\left. \begin{aligned} 0 &= \frac{dp}{dx} - \mu \frac{d^2 u}{dy^2} & 0 &= \frac{dp}{dy} & 0 &= \frac{dp}{dz} - \mu \frac{d^2 w}{dy^2}, & 0 &= \frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} \\ 0 &= p_{yx} - \mu \frac{du}{dy} & 0 &= p_{yz} - \mu \frac{dw}{dy}, & p_{xz} &= 0. \end{aligned} \right\} \quad (2)$$

For the boundary conditions, putting $f(x, z)$ as limiting the lateral area of the lubricant, the conditions at the surfaces may be expressed thus:—

$$\left. \begin{aligned} \text{when } y=0, \quad u &= U_0, \quad w=0, \quad v=0 \\ \text{when } y=h, \quad u &= U_1, \quad w=0, \quad v_1 = U_1 \frac{dh}{dx} + V_1 \\ \text{when } f(x, z)=0, \quad p &= p_0 \end{aligned} \right\} \quad (3)$$

Then, integrating the equations (2) over y , and determining the constants by equations (3), we have, since by the second of equations (2) p is independent of y ,

$$\left. \begin{aligned} u &= \frac{1}{2\mu} \frac{dp}{dx} (y-h)y + U_0 \frac{h-y}{h} + U_1 \frac{y}{h} \\ w &= \frac{1}{2\mu} \frac{dp}{dz} (y-h)y \end{aligned} \right\} \quad (4)$$

Then, differentiating equations (4) with respect to x and z respectively, and substituting in the 4th of equations (2), and integrating from $y=0$ to $y=h$, so that only the values of v at the

surfaces may be required, we have for the differential equation of normal pressure at any point x, z , between the boundaries:—

$$\frac{d}{dx} \left(h^3 \frac{dp}{dx} \right) + \frac{d}{dz} \left(h^3 \frac{dp}{dz} \right) = 6\mu \left\{ (U_0 + U_1) \frac{dh}{dx} + 2V_1 \right\} \quad (5)$$

Again differentiating equations (4), with respect to x and z respectively, and substituting in the 5th and 6th of equations (2), and putting f_x and f_z for the intensities of the tangential stresses at the lower and upper surfaces:—

$$\left. \begin{aligned} f_x &= \mu (U_1 - U_0) \frac{1}{h} + \frac{h}{2} \frac{dp}{dx} \\ f_z &= \mp \frac{h}{2} \frac{dp}{dz} \end{aligned} \right\} \quad (6)$$

Equations (5) and (6) are the general equations for the stresses at the boundaries at x, z , when h is a continuous function of x and z , μ and ρ being constant.

For the integration of equations (6) to get the resultant stresses and moments on the solid boundaries, so as to obtain the conditions of their equilibrium, it is necessary to know how x and z at any point on the boundary enter into h , as well as the equation $f(x, z)=0$, which determines the limits of the lubricating film. If y , the normal to one of the surfaces, has not the same direction for all points of this surface, in other words, if the surface is not plane, x and z become curvilinear co-ordinates, at all points perpendicular to y . Since, for lubrication, one of the surfaces must be plane, cylindrical, or a surface of revolution, we may put $x=R\theta$, $y=r-R$, and z perpendicular to the plane of motion. Then, if the data are sufficient, the resultant stresses and moments between the surfaces are obtained by integrating the intensity of the stress and moments of intensity of stress over the surface.

This, however, is not the usual problem that arises. What is generally wanted is to find the thickness of the film where least (h_0), and its angular position with respect to direction of load, to resist a definite load with a particular surface velocity. If the surfaces are plane, the general solution involves only one arbitrary constant, the least thickness (h_0); since in any particular case the variation of h with x is necessarily fixed, as in this case lubrication affords no automatic adjustment of this slope. When both surfaces are curved in the plane of motion there are at least two arbitrary constants, h_0 , and ϕ the angular position of h_0 with respect to direction of load; while if the surfaces are both curved in a plane perpendicular to the direction of motion as well as in the plane of motion, there are three arbitrary constants, h_0 , ϕ_0 , z_0 . The only constraint necessary is to prevent rotation in the plane of motion of one of the surfaces, leaving this surface free to move in any direction and to adjust its position so as to be in equilibrium under the load.

The integrations necessary for the solutions of these problems are practicable—complete or approximate—and have been effected for circumstances which include the chief cases of practical lubrication, the results having been verified by reference to Mr Tower's experiments. In this way the verified theory is available for guidance outside the limits of experience as well as for determining the limiting conditions. But it is necessary to take into account certain subsidiary theories. These limits depend on the coefficient of viscosity, which diminishes as the temperature increases. The total work in overcoming the resistance is spent in generating heat in the lubricant, the volume of which is very small. Were it not for the escape of heat by conduction through the lubricant and the metal, lubrication would be impossible. Hence a knowledge of the empirical law of the variation of the viscosity of the lubricant with temperature, the coefficients of conduction of heat in the lubricant and in the metal, and the application of the theory of the flow of heat in the particular circumstances, are necessary adjuncts to the theory of lubrication for determining the limits of lubrication. Nor is this all, for the shapes of the solid surfaces vary with the pressure, and more particularly with the temperature.

The theory of lubrication has been applied to the explanation of the slipperiness of ice. See *Manchester Memoirs*, 7th February 1899. (O. R.)

Lucca, a town, archiepiscopal see, and capital of the province of Lucca, Tuscany, Italy, 13 miles by rail north-east of Pisa. In the city, which is still encircled by its

mediæval walls, there is a marble monument to Duchess Maria Louisa, who in 1820 built the aqueduct of 459 arches which brings water from the Pisan hills. The cathedral treasures embrace sculptures and other artistic objects, and a collection of 4000 MSS. In San Francesco, one of the seventy churches, are the tomb of Castruccio Castracane and the mausoleum of the Guidiccioni; while the figure of the archangel which crowns San Michele is the most conspicuous object within the city walls. There are also a technical school and an institute of music. The river Serchio affords water-power for numerous factories. The most important branches of industry are the manufacture of jute goods, tobacco, silks, and cottons. Lucca was the birthplace of the sculptor Civitale (1436–1501), whose masterpieces adorn the cathedral and the church of the Santa Trinita. Population (1881), 68,063; (1901), 74,718.

LUCCA, BATHS OF.—The sketch in Heine's *Reisebilder: II. Italien*, should be mentioned. Population (1881), 8241; (1898), 9000.

Lucena, a town of Spain, in the province of Cordoba. The population in 1897 was 21,087. The local trade in agricultural products is still important, but the industries have greatly declined, except the manufactures of brandy, matches, and earthenware, especially the large jars used to contain oil or wine, some of which hold over 300 gallons.

Lucerne, one of the cantons of Switzerland, ranking next to Zürich and Bern. Its total area is 579 square miles; woods occupying 119 square miles; vineyards, 1; and arable or pasture land, 408½ square miles. The loftiest point in the canton is Pilatus (6995 feet), to near the summit of which a cog-wheel railway runs from Alpnach-Stad, while on the other side of the lake is the equally accessible and famous ridge of the Rigi (5906 feet). The population of the canton in 1880 was 134,708, and in 1900, 146,912. In 1900 there were 253 inhabitants to the square mile. The Protestants had risen from 3823 in 1870 to 12,406 in 1900; in 1888 there were 201 Jews, and in 1900, 336; the rest of the population was Romanist. Practically the whole population is German-speaking; there were 2302 Italians and 781 French-speaking persons in 1900. The cantonal constitution of 1875 has only been slightly modified. There is a legislature, elected in the fifty-five electoral circles by a popular vote, and holding office for four years, as does the executive of seven members, elected by the legislature. Five thousand citizens can demand a "facultative referendum" as to all legislative projects, or the revision of the cantonal constitution, and can also end the mandate of the cantonal legislature before its term of office has expired. In 1893 a cantonal vote refused to sanction the introduction of proportional representation as to the election of members of the cantonal legislature. The state revenue of Lucerne in 1897 was 2,115,860 francs (a rise of 33½ per cent. since 1885); and the state expenditure, 2,116,112 francs (a rise of 32½ per cent. since 1885); but in 1898 there was a deficit of 35,792 francs. In 1897 the public debt of the canton was 6,789,000 francs.

(W. A. B. C.)

Lucerne, the chief town of the Swiss canton of that name. Lucerne is the tourist capital of Switzerland, being on the main route between Basel (59 miles distant

by rail) and Italy *via* the St Gothard Railway. Its prosperity has always been bound up with the St Gothard Pass, so that the successive improvements effected on that pass (mule path in the 13th century, carriage road in 1820–30, railway in 1882) have always had much influence on its growth. In 1880 the population of the town was 17,758, and in 1900 it was 29,600. The inhabitants are mostly Romanist and German-speaking. In 1888 there were 2757 Protestants (as against 1912 in 1880) and 182 Jews, while 293 persons were French-speaking and 285 Italian-speaking.

The prehistoric antiquities, trophies from Sempach, &c., are all in the Rathhaus, not in the Cantonal Museum. It is the town (not the cantonal) library that is so rich in works relating to Swiss history; it is now the official centre wherein are gathered all such works or MSS. dating from before the Reformation. Next to the Lion Monument is the "Glacier Garden," a series of potholes worn in the rock bed of an ancient glacier by the action of water which whirls round stones; some of the actual stones still exist *in situ*.

The LAKE OF LUCERNE (*Vierwaldstättersee*) is often called the "Lake of the Four Forest Cantons" (*i.e.*, Uri, Schwyz, Unterwalden, and Lucerne), but this is a mistranslation, for "wald" does not here mean "forest," but is a historical corruption of "vallis," so that the name simply means the four Alpine valleys that lie round the lake. The area of the lake is 44½ square miles; of this 15½ square miles belong to the canton of Lucerne, 13 square miles to Nidwalden, 1 square mile to Obwalden, 7½ square miles to Uri, and 7½ square miles to Schwyz. Its height above the sea-level is 1434 feet, while its maximum depth is 702 feet. The Bürgenstein is properly the Bürgenstock, and thither a funicular railway leads up from Kehrsiten, while from Alpnach-Stad a line runs up to Pilatus, and from Vitznau another to the Rigi. Flüelen is the port of Atdorf, and Brunnen of Schwyz—in each case both places are on the St Gothard Railway. It is possible (though authentic history is silent on the point) that meetings on the Grütli (properly Rütli, *i.e.*, the little "clearing" in the forest) may have taken place before the first league of 1291, or the second (after Morgarten) in 1315. But the date of 1307 was invented by Tschudi, and is historically quite impossible. (W. A. B. C.)

Luchu Archipelago, The (called also RUKIU, Loo-choo, and LIUKIU), a long chain of islands stretching from a point 80 miles south of Kiushiu to a point 73 miles distant from the north-eastern coast of Formosa, and lying between 24° and 30° N. and 123° and 130° E. The almost equal proximity of the islands to Japan on the north and to the formerly Chinese island of Formosa on the south accounts for the dual allegiance their inhabitants paid for many years to the two neighbouring empires, and also for the mixture of Japanese and Chinese elements in their civilization. The islanders themselves carry their history far back into the ages, but we do not find ourselves upon unquestionably solid ground until the beginning of the 17th century, when the feudal chief of Satsuma, resenting an attempt on the part of the islanders to sever relations with Japan, invaded Luchu and annexed the northern section of the archipelago. China, on the other hand, though receiving periodically from the Luchuan presents which she interpreted as tribute, and though taking a benevolent interest in the welfare of the islanders, never made any display of force or attempted to bring them under her military sway. The practical incongruity of that state of affairs did not force itself upon Japan's attention so long as her own empire was divided into a number of semi-independent principalities. But in 1879 the Japanese Government, treating Luchu as an integral part of the Mikado's dominions, dethroned its prince, pensioned him as the other feudal chiefs had been pensioned, and converted Luchu into a prefecture under the name of Okinawa. This name signifies "extended rope," and alludes to the lengthy attenuated nature of the archipelago. China remonstrating, a conference was held in Peking, when plenipotentiaries of the two empires signed an agreement in the sense that the archipelago should be

divided equally between the claimants. The Chinese Government, however, refused to ratify this compromise, and the Japanese, abandoning all hope of an amicable settlement, continued their measures for the effective administration of all the islands. Ultimately (1895) Formosa also came into Japan's possession, and her title to the whole chain of islands is no longer disputed.

Japanese cartographers reckon the Luchu islands as 55, having a total coast-line of 768 miles, an area of 935 square miles, and a population of 453,550 (1898). They divide them into three main groups, of which the northern is called Oshima-shotô; the central, Okinawa-guntô; and the southern, Sakishima-rettô. The terms *shotô*, *guntô*, and *rettô* signify "archipelago," "cluster of islands," and "string of islands" respectively. The last-named group is subdivided into Miyako-guntô and Yayeyama-guntô. The principal islands of these various groups are:—

<i>Oshima-shotô</i> —	
Anami-Oshima	34 miles long and 17 broad
Tokuno-shima	16 " " 8½ "
<i>Okinawa-guntô</i> —	
Okinawa-jima	63½ miles long and 14½ broad
Kume-jima	9½ " " 7½ "
Okinoerabu-jima	9½ " " 5 "
Ihaya-jima	5 " " 2½ "
<i>Miyako-guntô</i> —	
Miyako-jima	12½ miles long and 12 broad
Erabu-jima	4½ " " 3½ "
<i>Yayeyama-guntô</i> —	
Ishigaki-jima	24½ miles long and 14½ broad
Iriomote-jima	14½ " " 14 "
Yonakuni-jima	7½ " " 3½ "

The remaining islands of the archipelago are of very small size. Almost at the extreme north of the chain there are two islands with active volcanoes: Nakano-shima (3485 feet), and Suwanose-jima (2697 feet), but the remaining members of the group give no volcanic indications, and the only other mountain of any size is Yuwan-dake (2299 feet) in Anami-Oshima. The capital town is Shuri in Okinawa, with a population of 24,809. The scenery of Luchu is unlike that of Japan. Though so close to the tropics, the islands cannot be said to present tropical features: the bamboo is rare; there is no high grass or tangled undergrowth; open plains are numerous; the trees are not crowded together; lakes are wanting; the rivers are insignificant; and an unusual aspect is imparted to the scenery by numerous coral crags. The climate is, of course, much warmer than that of Japan, the mean normal temperature in Nafa, the chief town of Okinawa, being 22° 5' C., whereas that in Tôkyô is only 14° C. The maximum range of the thermometer during summer does not greatly differ in the two places; but while the lowest reading for Tôkyô in winter is -6° 4' C., the corresponding figure at Nafa is 8° 3' C., a difference of over 14° C.

Luchu is noted for the production of particularly durable vermilion-coloured lacquer, which is much esteemed for table utensils in Japan. The islands also manufacture certain fabrics which are considered a speciality. These are *Riukiu-tsumugi*, a kind of fine pongee; the so-called *Satsuma-gasuri*, a cotton fabric greatly used for summer wear; *bashô-fu*, or banana-cloth (called also *aka-bashô*), which is woven from the fibre of a species of banana; and *hoso-jôfu*, a particularly fine hempen stuff, made in Miyako-jima, and demanding such difficult processes that six months are required to weave and dye a piece 9½ yards long.

It has been generally agreed by competent observers that although the upper classes in Luchu and Japan resemble each other almost to identity, there are palpable differences between the lower classes, the Luchuan being shorter and better proportioned than the Japanese, having higher foreheads, eyes not so deeply set, faces less flattened, arched and thick eyebrows, better noses, less marked cheek-bones, and much greater hairiness. The last characteristic has been attributed to the presence of Ainu blood, and has suggested a theory that when the Japanese race entered south-western Japan from Korea, they drove the Ainu northwards and southwards, one portion of the latter finding their way to Luchu, the other to Yezo. Women of the upper class never appear in public in Luchu, and are not even alluded to in conversation, but women of the lower orders go about freely with uncovered faces, attending market, carrying loads on their heads, and doing their share of agricultural labour. The Luchu costume

Popu- lation and customs.

resembles that of Japan, the only marked difference being that the men use two hairpins, made of gold, silver, pewter, or wood, according to the rank of the wearer. Young men shave their faces until the age of twenty-five, after which moustache and beard are allowed to grow, though the cheeks are kept free from hair. Their burial customs are peculiar. The corpse, immediately after death, is concealed by curtains and guarded by relatives, who also accompany it to the grave. The mourning, however, is done by professionals, who on the way to the tomb groan, stagger, and weep as though they were completely overcome with grief. Sepulchres are generally mitre-shaped, and are scattered all over the country, according to Chinese fashion. In the third year after interment, the nearest of kin wash the bones and deposit them "in earthenware urns of curious make, ornamented with the lotus and other emblems that bear witness to a formerly penetrating Buddhist influence, now almost extinct. The remains of married couples rest together in the same large urn. Bachelors and spinsters—but Luchu harbours few such—have urns half the size. All the urns of a family are ranged round the interior of the vault on shelves, in order of precedence." The marriage customs are still more peculiar. Preliminaries are negotiated by a middleman, as in China and Japan, but the subsequent procedure takes the following form:—"The bride is escorted to the man's house at one or two o'clock in the morning, surrounded by all her relations. . . . She and the bridegroom exchange cups of *sake*"—precisely the Japanese custom—"after which she is at once led home again. This brief ceremony is repeated three nights running, after which she remains three days with her parents, while the bridegroom is carried off by his friends to a brothel, where they hold high revel. The object of this step, so far as the man is concerned, is that he may, on the very threshold of matrimony, prove his independence of wifely leading-strings, while to the woman it gives an opportunity to display freedom from jealousy, which is considered the worst of all feminine vices. After three days spent in this manner, the bridegroom goes home, being joined by the bride, who keeps house with him for another period of three days, at the expiration of which the bride goes to her parents' home, whither the bridegroom follows her. Her relations await his arrival with a pestle, painted and ornamented to represent a horse, on which he rides in, while all the boys of the neighbourhood greet his advent with drums and tomtoms and anything that will make a noise. A grand family feast then takes place, after which the happy couple return home, and the long wedding ceremonies are at last concluded."

The chief staple of the people's diet is sweet potatoes, and pork is the principal luxury, as in China. An ancient law, still in force, requires each family to keep four pigs. In times of scarcity a species of sago (obtained from the *Cycas revoluta*) is eaten. The country is infested with venomous snakes called *habu* (*Trimeresurus*), which attain a length of from 6 to 7 feet and a diameter of from 2½ to 3 inches. Their bite generally causes speedy death, and in the island of Anami-Oshima they claim many victims every year. There is a remarkable absence of religious influence in Luchu. Places of worship are scarcely to be seen, and the only function now discharged by Buddhist priests seems to be to officiate at funerals. On the other hand, the people are distinguished by gentleness, courtesy, and docility, as well as by marked avoidance of crime and practical love of peace. With the exception of petty thefts, their Japanese administrators find nothing to punish, and for nearly three centuries no such thing as a lethal weapon has been known in Luchu. Professor Chamberlain records his opinion that the Luchuan language resembles the Japanese in about the same degree as Italian resembles French, and says that a little investigation proves the two to be sister tongues, many words being identical, others differing only by letter changes which follow certain fixed analogies, and sentences in the one being capable of translation into the other word for word, almost syllable for syllable.

(F. BY.)

Luckenwalde, a town of Prussia, on the Nuthe, 30 miles south of Berlin by rail, in the circle of Jüterbog-Luckenwalde, government district of Potsdam, province of Brandenburg. It has three Protestant churches, a Catholic church, a *real*-progymnasium, a higher-grade school, cloth, hat, bronze-ware, paper, and enamel factories, wool-spinning, and machinery works. Population (1890), 18,398; (1900), 20,986.

Lucknow, a city, district, and division of British India, the capital of Oudh, mainly on the right bank of the winding river Gunti, which is crossed by two railway and three road bridges, 364 feet above the sea; 46 miles by rail north-east of Cawnpore, and 610 miles from Calcutta. Area,

about 13 square miles. Population (1881), 261,303; (1891), 273,028; (1901), 263,951, being the fifth largest city in India. The municipality of Lucknow, with a population of 267,910, is governed by a board of 32 members, of whom 24 are elected, with the district magistrate as *ex officio* chairman. The municipal income in 1897-98 was Rs.3,96,439, of which Rs.2,70,961 was derived from octroi; incidence of taxation, R.1:2:2 per head. The water-works supply annually about 350,000,000 gallons of filtered water, at a total cost of about 6 annas per thousand gallons. During 1897-98, Rs.56,788 was expended on water-supply, Rs.6856 on drainage, and Rs.29,666 on other public works. The death-rate in 1897 was 55.03 per thousand, compared with an average of 42.47 for the previous five years. The chief educational institution is the aided Canning College, with an Oriental department; the number of students in 1896-97 was 258. There are also two unaided colleges, the Christian and the Women's, with a total of 34 students; the Colvin School, for sons of Taluqdars, the landlords of Oudh, with 32 pupils, of whom 14 were Mahomedans; the Crosthwaite Girls' School, for the higher education of native ladies, under an English lady superintendent, supported by an endowment of about Rs.2,00,000, with 19 pupils; the Martinière, where about 150 soldiers' children are educated entirely free of expense out of a foundation left by General Claude Martin in 1800; and several high schools. Mention should also be made of the Lady Lyall Hospital, with an endowment of about Rs.1,00,000; and of the Government lunatic asylum, with 247 inmates. There are about 140 printing-presses, issuing 3 English and 30 vernacular newspapers. The largest manufactory is a paper-mill, employing 550 hands, with an out-turn valued at Rs.7,60,000. There are also a flour-mill, and factories for ice and mineral waters. The native manufactures of gold and silver brocade, muslins, embroidery, glasswork, and moulding in clay maintain their reputation. Lucknow is the centre of the Oudh and Rohilkhand railway system, with large workshops. Lines radiate to Cawnpore, Bareilly, Gonda, Faizabad, and Rae Bareli. In 1898 the last line was extended to Benares, 139 miles. Lucknow is the headquarters of the Oudh military division. The cantonments, 3 miles east of the city, usually contain 3 batteries of artillery, and both European and native regiments of cavalry and infantry.

The district of LUCKNOW lies on both sides of the river Gumti. Area, 967 square miles; population (1881), 696,824; (1891), 774,163; and (1901), 793,334, showing an increase of 11 per cent. between 1881 and 1891, and of 2.47 per cent. between 1891 and 1901; average density, 820 persons per square mile; land revenue and rates, Rs.7,65,965, the incidence of assessment being R.1:7:0 per acre; cultivated area, 277,183 acres, of which 108,641 were irrigated from wells, &c.; number of police, 2591; number of vernacular schools (1896-97), 76, with 3244 pupils; death-rate (1897), 43.38 per thousand.

The division of LUCKNOW contains the western half of Oudh. It comprises the six districts of Lucknow, Unao, Sitapur, Rae Bareli, Hardoi, and Kheri. Area, 12,040 square miles; population (1881), 5,325,601; (1891), 5,856,559; and (1901), 5,977,116, showing an increase of 10 per cent. between 1881 and 1891, and of 2.06 per cent. between 1891 and 1901; average density, 496 persons per square mile. (J. S. Co.)

Lucon, a French town in the arrondissement of Fontenay-le-Comte, department of Vendée, 19 miles south-east of La Roche sur Yon, on the railway from Nantes to Bordeaux, and on the canal of Lucon (9 miles long), which affords communication with the sea in the Bay of Aiguillon. Between Lucon and the sea stretch wide marshy plains, the bed of the former gulf, partly drained by numerous canals, and in the reclaimed parts yielding excellent pasturage, while in other parts are productive salt-marshes, and ponds for the rearing of mussels and other shell-fish. Lucon is the seat of a bishopric, estab-

lished in 1317, and held by Richelieu from 1607 to 1624, but the cathedral church, partly of the 11th century and partly of various later periods, was originally an abbey church. The façade and the clock tower date from about 1700, and the tower is surmounted by a notched spire rising to a height of 275 feet above the ground, attributed to the architect François Leduc of Tuscany. In the choir, which dates from the 14th century, are some remains of mural paintings. The cloisters are of the 15th or 16th century. Adjacent is the bishop's palace, with a theological library of 30,000 volumes, and there is a very fine public garden. The town has some small industries, including the manufacture of liqueurs, mustard, clogs, and boot-heels, and iron and copper founding. Population (1881), 5835; (1901), 6757.

Lüdenscheid, a town of Prussia, province of Westphalia, 19 miles by rail south-south-east of Hagen. It is the seat of various hardware manufactures (metal-plated and tin-plated goods, buckles, fancy nails, &c.), iron-foundries, and machine shops, and has a couple of churches, and monuments to the Emperor William I. and the war of 1870-71. Population (1885), 15,067; (1900), 25,520.

Ludhiana, a town and district of British India, in the Jullundur division of the Punjab. The town is 8 miles from the present left bank of the Sutlej, 228 miles by rail north-west of Delhi. Population (1881), 44,163; (1891), 46,134; municipal income (1897-98), Rs.84,381; death-rate (1897), 46 per thousand. It is an important centre of trade in grain, and has manufactures of shawls, &c., by Kashmiri weavers, and of scarves, turbans, furniture, and carriages. The municipality has raised a loan of Rs.38,000 for sewerage works. There is an American Presbyterian mission, besides a medical school for Christian women, founded in 1894, with a staff of four lady doctors and 24 students in 1896-97; three high schools, including a Christian boys' boarding-school; 2 middle schools; a Sanskrit school; and an industrial school, opened in 1896, with 77 pupils. There are ten printing-presses, issuing five newspapers and periodicals, and four religious and educational associations.

The district of LUDHIANA lies south of the river Sutlej, and north of the native states of Patiala, Jhind, Nabha, and Maler Kotla. Area, 1453 square miles; population (1881), 618,835; (1891), 648,722; (1901), 673,502, showing an increase of 5 per cent. between 1881 and 1891, and of 3.82 per cent. between 1891 and 1901; average density, 463 persons per square mile. The land revenue and rates in 1897-98 were Rs.11,16,131, the incidence of assessment being R.1:4:2 per acre; cultivated area, 660,236 acres, of which 275,292 were irrigated from wells, &c., including 91,383 from Government canals; number of police, 507; number of schools (1896-97), 275, attended by 9489 boys, being 16 per cent. of the boys of school-going age; death-rate (1897), 34.7 per thousand. The principal crops are wheat, millet, pulse, maize, and sugar-cane. The district is crossed by the main line of the North-Western railway from Delhi to Lahore, 35 miles. Part of it is watered by the Sirhind canal.

Ludington, a city of Michigan, U.S.A., capital of Mason county, on the western shore of the Lower Peninsula of Michigan, on the Pere Marquette railroad, at an altitude of 587 feet. It has an excellent harbour and much lake commerce. It contains several saw-mills and other wood-working establishments. Population (1880), 4190; (1890), 7517; (1900), 7166.

Ludinovsk, a town of Russia, government of Kaluga, 27 miles by rail from the Zhukovka station of the Orel and Smolensk railway. It belongs to the group of iron and glass works, the so-called "Maltsoff's Works." It was founded in 1755, but attained its present importance after 1875, when iron works and large locomotive and railway-carriage works were opened. Population (1897), 12,000.

Ludwig II., Otto Friedrich Wilhelm, king of Bavaria (1845–1886), was born at Munich on the 25th of August 1845, as eldest son of Prince Maximilian, son and heir to the king, Ludwig I. His mother was Maria, daughter of Prince William of Prussia (brother of King Friedrich William III.), and therefore first cousin to the Emperor William I.; she joined the Roman Catholic Church in 1874, and died in 1889. During the revolution of 1848 Ludwig I., whose passion for Lola Montez had caused a temporary quarrel between him and his subjects, abdicated; he lived in retirement till 1868. Maximilian, who then succeeded, died on the 10th of March 1864; Ludwig therefore came to the throne at the early age of eighteen. From both his father and grandfather he had inherited a keen interest in art, and almost the first use which the young king made of his power was to summon Richard Wagner to Munich. Admiration for his musical genius became the basis for a warm personal friendship, which was looked on with much displeasure by the people of Munich, and especially by the Clerical party, who declared that Wagner was a Prussian agent. The king caused his operas to be performed, and formed great projects of establishing a new school of music under Wagner's direction, as well as of enabling the musician to realize his dream of a magnificent festival-house for opera and concerts, a plan to which he was naturally attracted by his hereditary taste for building. He was, however, compelled to give way before the opposition of his ministers and subjects, and had eventually to request Wagner to leave Munich. The friendship thus begun continued till Wagner's death; on more than one occasion the king visited him privately in Switzerland, and he gave valuable support and assistance to the erection of the opera-house at Bayreuth. From the first Ludwig's interest in political affairs was spasmodic and uncertain; he showed at times much intelligence and insight, but after the first year of his reign he avoided appearing in public, and caused much inconvenience to his ministers by prolonged absence. His strongest feeling was dislike to the Ultramontanes, and in this he continued the policy of his house, but it was increased by their opposition to Wagner. He took no part and apparently little interest in the crisis of 1866, though the very existence of Bavaria was in danger, but after the war was over he gave his warm support to the Liberal ministry of Hohenlohe, and characteristically, as a symbol of the new alliance with Prussia, offered the Prussian king the joint ownership of the castle of Nuremberg, the ancient home of the Hohenzollerns. When Hohenlohe was defeated in the election of 1869 the king refused to accept his resignation, and would not receive a deputation from Parliament which called to present an address praying him to dismiss his ministers: he reprimanded those members of the royal family, including his uncle Prince Luitpold, who had voted against his ministers. He was obliged eventually to accept Hohenlohe's resignation, but his dislike of the Ultramontanes was of much value to Germany, when in 1870 he came for a short term into a position of great political importance. A considerable party in Bavaria would gladly have refused the assistance which by treaty they were bound to give to Prussia; the king, however, by promptly ordering the mobilization of the army, ensured the fidelity of Bavaria to the German cause. As in 1866, he took no part in the campaign, and he was one of the very few German princes who never appeared at Versailles; Bavaria was represented by Prince Luitpold. As ruler of the chief of the German states, it fell to Ludwig, in the name of the German princes, to invite the king of Prussia to assume the title of emperor. This he did in a letter of 17th November to the king and in a circular

despatch to the rulers of the other states. His name thereby was closely associated with the foundation of the empire, and the reputation of a patriotic prince added to the popularity which his artistic interests, his personal appearance, and his romantic habits had already secured him. Both letters, as is now known, were copied from drafts sent to him by Bismarck, for the king was unable to bring himself without assistance to take this step. While he acquiesced in the new position which Bavaria occupied, he did not always succeed in veiling the jealousy with which he regarded the new greatness of the Hohenzollerns. In the following years he continued his support to the Liberals, though he scarcely ever spoke to his ministers, and protected the Old Catholics and Döllinger, who had been his tutor, when they refused to accept the Papal infallibility. As years went on the marks of the mental disease to which he finally fell a victim became more apparent. A visit to Paris in 1874 stirred up afresh the passion for building. He seems to have taken Louis XIV. and Louis XV. as his models. Already he had made great additions to the castle of Hohenschwangau, which had been erected by his father; he built two magnificent palaces at Neu Schwanstein and Lindenhof in the Bavarian highlands; then he began a fourth, which was to be an imitation of Versailles, not only in style but in magnificence, on an island in the Chiemsee. Financial difficulties caused by this profuse expenditure made it necessary to interfere. An inquiry ordered by the ministers disclosed abundant evidence of insanity, of which the most marked symptom was the avoidance of all human intercourse, and on 10th June 1886 a proclamation was published creating Prince Luitpold regent on the ground that the king was incapable of reigning. The procedure was that required by the constitution. After some difficulty Ludwig, who attempted to resist, was placed in confinement in Berg, one of the royal palaces. On 13th June he was allowed to go out walking with a single medical attendant; in the evening both were discovered drowned in the lake adjoining the castle. It is probable that the king had attempted to escape by swimming across the lake, and that the doctor had been drowned in the attempt to prevent this.

Ludwig was unmarried, an engagement to the Duchess Sophie, daughter of Maximilian, duke of Bavaria, having been broken off. He was therefore succeeded by his only brother, Otto (born 1848). As the new king had since 1872 suffered from an incurable mental disease, PRINCE LUITPOLD was reappointed regent. He was born on the 12th of March 1821, and was the third son of King Ludwig I., the second being Otto, king of Greece, who had died without issue. Though more favourably inclined to the Clerical party than his nephew had been, he made no sudden change in the Government, but he gradually brought to an end the long struggle over the Old Catholics. While a loyal adherent of the imperial constitution, he showed himself able to maintain the privileges and dignity of Bavaria as an equal ally of Prussia. In case of the death of King Otto the succession rested with him or his sons. He married a daughter of Leopold II., grand duke of Tuscany, and his two eldest sons, Ludwig and Leopold, were also married to Austrian princesses, one to Marie of Modena, the other to Gisela, daughter of the emperor of Austria; both had numerous families, so that the continuance of the succession appears secured.

Ludwig, Carl Friedrich Wilhelm (1816–1895), German physiologist, was born at Witzenhausen, near Cassel, on 29th December 1816. After attending the gymnasium at Hanau, he studied medicine at Erlangen and Marburg, taking his doctor's degree at the latter university in 1839. He made Marburg his home for the next ten years, studying and teaching anatomy and physiology, first as prosector to Fick (1841), then as *privat-docent* (1842), and finally as extraordinary professor (1846). In 1849 he was chosen professor of anatomy and physiology at Zürich, and six years afterwards he went to Vienna as professor in the Josephinum (school for military surgeons). In 1865 he assumed the duties of the newly-created chair of physiology at Leipzig, and continued to perform these for thirty years, until his death on 23rd April 1895. Ludwig's name is prominent in the history of physiology, and he had a large share in bringing about the change in the method of that science which took place about the middle of the 19th century. Together with his friends Helmholtz, Brücke, and du Bois-Reymond, whom he met for the first time in Berlin in 1847, he rejected the assumption then generally accepted that the phenomena of living animals depend on special biological laws and vital forces different from those which operate in the domain of inorganic nature; and, insisting that they are to be defined in physical and chemical terms, he sought to explain them by reference to the same laws as are applicable in the case of physical and chemical phenomena. This point of view was expressed in his celebrated *Text-Book of Human Physiology* (1852–56), which was dedicated to the three friends mentioned above, but it is as evident in his earliest paper (1842) on the process of urinary secretion as in all his subsequent work. As an original investigator, Ludwig exercised enormous influence on the progress of physiology, not only by the discoveries he made, but also by the new methods and apparatus he introduced to its service. Thus in regard to secretion, he showed that secretory glands, such as the submaxillary, are something more than mere filters, and that their secretory action is attended by chemical and thermal changes both in themselves and in the blood passing through them. He demonstrated the existence of a new class of secretory nerves that control this action, and by showing that if the nerves are appropriately stimulated the salivary glands continue to secrete, even though the animal be decapitated, he initiated the method of experimenting with excised organs. In studying the movements of the blood and lymph in the body, he devised the kymograph as a means of obtaining a written record of the variations in the pressure of the blood in the blood-vessels; and this apparatus not only conducted him to many important conclusions respecting the mechanics of the circulation, but afforded the first instance of the use of the graphic method in physiological inquiries, to which it has since been widely applied. For the purpose of his researches on the gases in the blood, he designed the mercurial blood-pump which in various modifications has come into extensive use, and by its aid he made many investigations on the gases of the lymph, the gaseous interchanges in living muscle, the significance of oxidized material in the blood, &c. There is indeed scarcely any branch of physiology, except the physiology of the senses, to which he did not make important contributions. He was also a great power as a teacher and the founder of a school. A keen judge of the abilities of his pupils, he had also a remarkable faculty for awakening their enthusiasm and for inciting them to do the best of which they were capable. Under him the Physiological Institute at Leipzig became an organized centre of physiological research, whence issued a steady stream of original work; and though the papers containing the results usually bore

the name of his pupils only, every investigation was inspired by him and carried out under his personal direction. Thus his pupils gained a practical acquaintance with his methods and ways of thought, which could scarcely have been acquired by mere attendance at lectures, and, coming as they did from all parts of Europe, they returned as apostles to their own countries to spread and extend his doctrines. It need scarcely be added that Ludwig was no anti-vivisectionist. Possessed himself of extraordinary manipulative skill, he abhorred rough and clumsy work, and he insisted that experiments on animals should be planned and prepared with the utmost care, not only to avoid the infliction of pain (which was also guarded against by the use of an anaesthetic), but to ensure that the deductions drawn from them should have their full scientific value. (H. M. R.)

Ludwigsburg, a town of Germany, in Würtemberg, 9 miles north of Stuttgart by rail. It contains the magnificent palace of the kings of Würtemberg. In 1882 the sculptor Hofer presented to the town a marble statue of Schiller. It has developed considerable industrial activity in organs, chemicals, cloth, linens, cottons, gold and silver wire, and beer. Population (1885), 16,201; (1900), 19,359.

Ludwigshafen, a rapidly-growing industrial town of Bavaria, Germany, on the left bank of the Rhine, immediately opposite to Mannheim, in the Palatinate district. It has a fast-increasing trade in iron, timber, coal, and agricultural products, a trade which is fostered by a free harbour (opened in 1897); and also large factories for aniline dyes and soda, iron-foundries, and production of cellulose, artificial manure, artificial wool, vehicles, flour and malt, saw-mills and breweries. The place, which was first founded in 1843, was only made a town in 1859. Population (1885), 21,042; (1900), 61,905.

Ludwigslust, a town of Germany, grand-duchy of Mecklenburg-Schwerin, 22 miles by rail south by east of Schwerin. The castle, built by Duke Christian Ludwig in 1772–79, was the favourite autumn residence of the grand-duke. There are also a couple of other ducal residences, a fine park, and a monument of the Grand-Duke Frederick Francis I. (1869). The parish church is in the form of a Greek temple. Population (1900), 6634.

Lugano, the most important town in the Swiss canton of Tessin or Ticino, though Bellinzona is the sole political capital. It is 124½ miles by the St Gothard railway from Lucerne, and 48½ miles from Milan. The ancient church of San Lorenzo has since 1888 been the see of the bishop of Lugano, which is held for the present with that of Basel. There are railways from Lugano (902 feet) up Monte San Salvatore, and up Monte Generoso opposite. Population (1888), 7097; (1900), 9553.

Lugano, Lake of, has an area of 19.4 square miles, of which 7.5 square miles belong to Switzerland and 11.9 square miles to Italy. It is 899 feet above the level of the sea, while its greatest depth is 945 feet. It is traversed between Melide and Bissone by a great stone dam (with openings at each end), over which the high road and the St Gothard railway are carried.

Lugansk (also LUGAÑ and LUGANSKIY ZAROD), a district town of Russia, government and 143 miles north-east of Ekaterinoslav, on the Catherine railway. It has a gymnasium, a technical railway school, and a first-class meteorological observatory, besides cast-iron, steel, and cartridge works belonging to the Crown, distilleries, breweries, tanneries, soap and candle works, and steam flour-mills. Population (1897), 20,419.

Luganskaya, Cossack village of Russia, province of the Don Cossacks, on Lake Stanichnoye, 70 miles east of Bakhmut railway station. It is a wealthy village, with considerable trade in corn and exports of different kinds of raw produce, &c. Population (1897), 20,381.

Lugo, a town of the province of Ravenna, Emilia, Italy, 18 miles west of Ravenna, on a branch line which joins the Bologna-Brindisi railway at Faenza. An important fair is held during September. There are manufactures of ropes, furniture, and ironmongery. Population, 17,500.

Lugo, a maritime province in the north-east of Spain. Its area is 3787 square miles, divided into 11 administrative districts and 64 parishes. The population is increasing, despite the flow of emigrants to Portugal and South America, and numbered 459,119 persons in 1897. The birth-rate is 3.31 per cent. and the death-rate 2.86 per cent.; the proportion of illegitimate births is very high—10.30 per cent. The means of communication are insufficient, though there are 98 milés of first-class roads, and the railway from Valencia to Corunna runs through the province. The only important industries are those connected with leather, preserves, coarse woollen and linen stuffs, timber and osier work. About 250 coasting vessels are registered at the ports, and about as many boats constitute the fishing fleet, which brings in lampreys, soles, tunny, and sardines, the last two being salted and tinned for export. The mountainous parts are still well wooded. Agriculture is in a very backward condition, mainly owing to the extreme division of land that prevails throughout Galicia, and cattle-rearing has declined in consequence of the cessation of the export trade to Great Britain. The live stock numbered in 1898, 11,305 horses, 2213 mules, 1880 asses, 120,793 cattle, 136,512 sheep, 30,885 goats, and 108,263 pigs. There were only six productive mines in 1898, four of coal and two of antimony, while the unproductive mines numbered 132.

Lugo, town in Spain, on the Minho, 51 miles east by north of Santiago, capital of the province of the same name. It has extended much beyond the fine old Roman walls. The chief local industries are tanning and the manufacture of linen and woollen stuff. Nine new suburbs, thickly peopled, have sprung up around the old city. Population (1897), 25,568.

Luitpold, OF BAVARIA. See LUDWIG II.

Luleå, a seaport town of Sweden, capital of the county of Norrbotten, on the peninsula of Sandö, at the mouth of the Luleå (river Lule), near the north-west corner of the Gulf of Bothnia, connected at Boden (22 miles to the north) with the main line of railway from Stockholm to the north of Finland, and the seaward terminus of the Luleå-Ofoten railway. It is the shipping place of the iron ore mined at Gellivare, 127 miles north by west. The quantity of iron exported increased from 21,000 tons in 1880 to 1,054,575 tons in 1900. The only other export of moment is timber, of which 4 to 7 million cubic feet are exported annually (over 7 million cubic feet in 1899). The port was cleared by 191 vessels of 79,300 tons in 1887 and by 446 vessels of 630,503 tons in 1900, of which 126 of 212,668 tons were British. As a rule, the port is closed to navigation by ice from November to the end of May. The southern entrance to the harbour was in 1893 deepened to admit vessels drawing 23 feet, and in 1901 a beginning was made with the widening of it to double its present width, and with the construction of additional quays. The town was almost entirely burnt down in 1887, and its buildings are new—the church (1888-93), the Norrbotten Museum, and a technical

school being the most important. Population (1880), 3120; (1890), 4755; (1900), 9484. The district between Luleå and Boden is well cultivated, and had in 1897 a population of about 20,000.

In the years 1884-87 a railway line was laid temporarily from Luleå to Gellivare (127 miles; to the mines, 131 miles) by an English company; but in 1889 the company failed, and in 1891 the line was taken over by the Swedish Government, who paid £362,210 for it, and completed the line in 1892-94 at a further cost of £155,560. In 1898 the Swedish Parliament voted £1,194,350 for the continuation of the line from Gellivare, past the iron-fields of Kirunavaara and Luossavaara (68 miles farther north) to the Norwego-Swedish frontier, a distance of 147 miles from Gellivare. In the same year the Norwegian Parliament voted £472,220, and in 1900 an additional sum of £180,500, for the building of the Norwegian section of the line from Victoria Harbour (or Narvik) on Ofoten Fjord up to the frontier, a distance of 26 miles; Luleå to Victoria Harbour, 300 miles. When the Gellivare-Ofoten portion of the line is finished, it will enable the iron ore to be shipped in winter on the Norwegian side.

Lunacy. See INSANITY.

Lund, a university town of Sweden, 11 miles north-east from Malmö, on the railway to Stockholm. In 1899 the university was attended by 626 students, there being about 110 professors and lecturers. In 1897 the university library numbered about 163,000 volumes and 4900 MSS. Important buildings include the botanical museum, with gardens, an astronomical observatory (55° 41' 52" N. and 13° 11' 15" E.), built in 1866, though observations had been carried on since 1760; the university hall (1878-82); the academic union of the students (1851), containing an art museum; the museum (1882) of the History of Civilization (*Kulturhistorie*) Society, with valuable ethnographical and industrial art collections, illustrating life in southern Sweden from early times; All Saints' Church (1887-91); a diocesan school (1896), normal school for women, deaf and dumb school, and technical school. The industries are chiefly sugar-refining, iron-works, brick-works, and manufacture of furniture and gloves. Population (1880), 14,304; (1900), 16,621.

Lund, Troels Frederik (1840—), Danish historian, was born in Copenhagen on the 5th of September 1840. His father's first wife was the sister of the celebrated philosopher, Sören Kierkegaard, who exercised a considerable influence on the early years of the historian. Troels Lund was long in discovering the bent of his own mind. He entered the university as a student in 1858, read Plato, wrote verses, and vaguely determined to become a zoologist. Circumstances enabled him to prolong his youth in dreams and the contemplation of outdoor life. About the age of thirty he took a post under Government, which brought before his notice the treasures of the secret archives of Denmark. Curiosity awakened in him an overpowering interest; he pushed his researches farther and farther until he became a historian. His first work, however, *Historical Sketches from Unpublished Sources*, did not appear until 1876, but after that time his activity was stupendous. In 1879 was published the first volume of his *History of Daily Life in Denmark and Norway at the Close of the 16th Century*, of which the fourteenth volume appeared in 1901. Troels Lund was the pioneer of the remarkable generation of young historians who came forward in the North about 1880, and he remained the most original and most conspicuous of them. His principal peculiarity, in which he is already imitated by a school not only at home, but in Germany, Sweden, and Norway, is his neglect of purely political history. Saying very little about kings, armies, and governments, he concentrates his attention on the life, death, employments, pleasures, and prejudices of the ordinary men and

women of the age with which he deals, using to illustrate his theme a vast body of documents hitherto neglected by the official historian. The penultimate volume of his great work—called *The Illumination of Life*—treats a wider theme than any of the preceding, and aims at a rapid study of the advance of moral light after the Renaissance. The other writings of Dr Troels Lund are either polemical, or are chips from his central workshop. He has the charm of a singularly animated and lucid style, which reminds the English reader in some degree of that of Froude. Dr Lund was appointed historiographer-royal to the king of Denmark and comptroller of the Order of the Dannebrog. There was probably no living man to whom the destruction of the archives, when Christiansborg Castle was accidentally burned in 1884, was so acute a matter of distress. But his favourite and peculiar province, the MSS. of the 16th century, was happily not involved in that calamity.

Lundenburg (Czech, *Břeclava*), a town in South Moravia, on the Thaya river, on the border of Lower Austria. In the Middle Ages it was the Moravian capital and ducal residence. A short distance from Lundenburg is an estate of Prince Liechtenstein (Eisgrub), with a park over a hundred square miles in area, containing two small towns and several villages, together with various ornamental buildings, including a château in the style of Windsor Castle. Lundenburg has important markets, a considerable industry (sugar, starch, brewing, and distilling), and trade in timber. Population (1890), 5968; (1900), 6776, chiefly German.

Lüneburg, a town of Prussia, province of Hanover, on the river Ilmenau (a tributary of the Elbe), 30 miles by rail south-east of Hamburg. A museum (1891) with industrial, art, and natural science collections, and the bronze statue of the Emperor William I. (1898) are the principal new features. Besides its salt-works, brine spring, and gypsum quarries, Lüneburg has lime-kilns, cement factories, iron-works, carpet and artificial manure factories. It is also noted for its gardening, and has a trade in wine. Population (1885), 19,336; (1900), 24,693.

Lunel, a town, arrondissement of Montpellier, department of Hérault, France, 15 miles east-north-east of Montpellier, on the railway from that place to Tarascon, and at the head of the Lunel canal, which connects it with the *étang* of Maugio on the Mediterranean, and with the Cette-Rhône canal. The church, partly Romanesque, contains some old paintings, and in the Place de la République is a small copy of Bertholdi's statue, "Liberty enlightening the World." Absinthe is distilled, and trade is still carried on in wine, but the ravages of the phylloxera have greatly reduced the production in the district. The traffic on the Lunel canal in 1900 was represented by 338 boats, carrying over 9000 tons of merchandise, chiefly agricultural products and provisions. Population (1881), 6056; (1901), 7532.

Lunéville, chief town of arrondissement, department of Meurthe-et-Moselle, France, 17 miles east-south-east of Nancy, on the railway from Paris to Strasburg. The War Monument, commemorative of 1870-71, stands opposite the Hôtel de Ville, and there are statues of the Conventional Abbé Grégoire (d. 1831) and of General Lasalle (d. 1809). The gardens around the château now form a public promenade. Manufactures are very important, and include, among other things, cotton and silk hosiery, watch-glasses, porcelain, toys, fruit essences, and automobiles. There are salt-works and glass-works in some of the suburbs. Population (1881), 14,379; (1891), 16,530; (1901), 23,269.

Lungchow, a town in the province of Kwangsi, China, situated in 22° 21' N. and 106° 45' E., near the Tongking frontier. It was selected as the seat of frontier trade by the French convention of 1886, and was opened in 1889, but the overland trade so far has been insignificant. In 1898 the total value amounted to only H. taels 134,000 (£20,000), and in 1899 to H. taels 85,000 (£12,700). It is proposed to extend the Tongking system of railways, which is completed as far as Langson, to Lungchow, and thence to the large Chinese town of Nanning on the West river. Lungchow is a Chinese military station of some importance. It has a civilian population of about 22,000.

Lushai Hills, The, a district of British India, in the south of Assam. It consists of two tracts, formerly known as the North and South Lushai Hills, the latter of which was transferred from Bengal to Assam in 1898.

The Lushais or Kukis are a numerous tribe, who differ from their neighbours in recognizing hereditary chiefs. Some of them live in the Chittagong Hill Tracts, and a few have settled in Assam. But their home is the mountainous region that extends from Tipperah in Bengal to the Chin Hills of Burma. Order is now maintained by a military police force of 1000 men, with its headquarters at Aijal. The area of the North Lushai Hills is estimated at 3500 square miles. The population of the district (North and South Lushai Hills) was 82,344 in 1901. A house-tax is levied at the rate of Rs.2 per house, yielding Rs.15,263 in 1897-98. Each house is also liable to supply one coolie to work for ten days in the year, being paid 8 annas a day. In 1897-98 the quantity of labour thus impressed was equal to 65,393 days. The total expenditure on public works, chiefly roads, was Rs.1,10,303. Two missionaries, who handed over their work in 1898 to the Welsh Calvinistic Mission, have established a school at Aijal, with 68 boys, and have also reduced the Lushai language to writing, a dictionary and handbook having been printed by the Government press at Shillong.

Lussin, a small but important island in the Quarnero, in the Austrian crownland of Istria, lying west and south of Cherso, with which it is connected by a turn-bridge. It is 24 miles in length, and is little more than 300 yards in breadth at its narrowest point. Together with the adjacent islands of Cherso and Veglia it forms the government district of Lussin. Population of the island (1890), 11,838; (1900), 11,615; of the government district (1890), 39,989; (1900), 41,030, of whom about one-fifth were Italian, the remainder Serbo-Croatian. **LUSSIN-PICCOLO**, the chief town and principal harbour, is the most important trading centre of the Quarnero islands. It is one of the largest and most frequented harbours of the monarchy, a steamship station of the Austrian Lloyd, and a popular winter resort, with a climate resembling that of Nice. Population (1890), 7634; (1900), 7207. **LUSSIN-GRANDE**, on the east side of the island (2349 inhabitants), has an old Venetian palace and a shipbuilding wharf.

Lutherans.—Although since 1871 the German empire has been united for military and foreign purposes, and although since the 1st of January 1900 a certain partial unification of laws has taken place throughout the empire, yet each of the smaller states still retains its own reigning sovereign, its parliament, and its own Evangelical Church. Moreover, even where smaller states have been absorbed into the kingdom of Prussia as provinces, *e.g.*, Nassau or Hanover, their old distinct church establishments continue under the title of provincial churches, and the original church of the kingdom itself is known as that of "Old" Prussia. There is thus no corporate unity yet subsisting between the various state Evangelical bodies, and even the more strictly separated "Old" Lutherans still continue to maintain distinct from the state their "Evangelical Lutheran" congregations. Within each state church the two schools exist side by side, Orthodox and Reformed, or

conservative and liberal, as they are called. It depends upon accidental circumstances of appointment or election whether the teaching in any parish is of one kind or the other; sometimes, where there is more than one minister, it may be of both. With the growth of rationalism the liberal theology of the Evangelical churches has become scarcely distinguishable from Unitarianism, so that even within the limits of any "State Evangelical United Church" (*Evangelische Unirte Landeskirche*) the widest differences of doctrine may and do prevail. In the meantime a voluntary biennial conference is held at Eisenach, where matters of general interest may be discussed; but its resolutions have no necessarily unifying influence, and certainly have no binding force. A committee was in 1902 formed at Gotha, at the instance of the German emperor, to inquire into the feasibility of a general union of the (about) thirty Evangelical sects.

Evangelicals may be said to form about 58 per cent. of the population of the German empire, which in 1895 was 52,250,000, as against 39 per cent. of Roman Catholics. These are the two leading religions of Germany, about 3 per cent. only of the population in general being members of other religious bodies. The figures vary very much, as there is a continuous change going on from one to the other, and as there is a large emigration to countries beyond the seas. Since the formation of the empire, inland migration from one state to another has been much greater than before, a thing due to the wide appointment of officials and the dispersion of the army, to the vast increase of opportunities of industrial employment, to the greatly developed facilities of travel between the states, and other causes. This migration has brought about an increasing frequency of intermarriages between Protestants and Catholics, which forms a very important factor in religious change. It would appear that Catholicism increases in Eastern Prussia, Bavaria, Saxony, and Württemberg, whilst Evangelicalism, at least nominally, is increasing in large cities and in general throughout the rest of Germany. It has been calculated that in Prussia alone Evangelical ministry must be provided for persons speaking twenty different languages.

The Evangelical theory still holds that in each state the sovereign is the religious ruler or *summus episcopus*. He appoints a minister of public worship, and through him nominates the members of a governing body, called in the older states an *Oberkirchenrath* or Supreme Church Council, and in the newer states a *Consistorium*. This governing body deals with property, patronage, and other ruling and legal matters. Each parish, on the other hand, elects its own parish council for parochial affairs, church tax assessments, &c., and this council possesses legal rights. Delegates from these parish councils form the *Landessynode* or National Synod, which is a kind of church parliament. In cases that call for it, committees of the consistory and synod confer. Those who are entitled to vote for parochial councils do not, however, take very great part in the elections, except in Alsace-Lorraine, where nearly half the voters go to the poll.

The income of the Evangelical churches is derived from four sources. The state makes an annual provision for clergy stipends, officers' salaries, church maintenance, &c., and sometimes makes special grants for improvement of stipends, supply of assistant-clergy, for widows and orphans of clergy, for preaching seminaries, &c. Then there are endowments or bequests of various kinds, twenty-four such in Prussia alone, administered by the Supreme Council; these relate to foreign missions, pensions of aged clergy, supply of books to clergy, &c. A third source of income are the various voluntary collections, which in England are made by the Church societies and even by individual appeals, such as those for building churches, parsonages, mission-rooms, institutes, &c.; these are in Germany all swept into the common income of the national churches, and are regulated by the Supreme Council or Consistory. Fourthly, each parish is entitled by law to levy a church rate upon its adherents, and the proceeds are applied to certain objects defined by the same law.

Appointment to benefices lies in the hands of the state (with sometimes the consent of parishes), of private patrons, and of local parish councils. The number of benefices increases yearly; in 1897 there were in all Germany 16,400, or 300 more than in 1890. Of these the state appoints to 56 per cent., private and municipal patrons to 34 per cent., the local congregations to 10 per cent. Customs vary in different states; e.g., in Schleswig-Holstein, although the parish elects, the state nominates; in Alsace and Lorraine all clergy are appointed by the consistory (here called the *Directorium*), with the approval of the *statthalter* or viceroy; and in Baden, although the state appoints, the congregation elects one out of six names put forward by the Government.

Aspirants for the Evangelical ministry, having passed through the secondary schools and the customary matriculation examination, attend at least six lecture terms in the theological department of a university. They then pass the examination for a preaching licence ("*pro licentia concionandi*"), after which two years elapse, during one of which the "candidates" study at a preachers' seminary. Then follows the examination "*pro ministerio*," after which they are eligible for election to cures or assistant-cures of souls. Before entering upon work they are ordained at a public service in church, with laying on of hands by the general superintendent and one other minister. About 27 per cent. of the clergy come from families of better position, but there is a great falling off in general in the number of candidates. In Old Prussia the number of *students* during the decade 1888-98 went down by one-half, and the number of *ordinations* showed a decrease of 28 per cent.

The union of two forms of Protestant Christianity in the Evangelical churches has resulted in vagueness of teaching and principle in most cases, and in a very widespread freedom of thought. Many of both clergy and laity do not believe in the miraculous birth of Christ; many criticize very freely the narrative of the New Testament, and cannot accept the statements of the Apostles' Creed. Under the name of Higher Criticism many sceptical views are published and preached, denying the doctrine of the Holy Trinity. From this arises a general vagueness which is a source of weakness to the Evangelical religion. On the one hand, there is a general unity in promoting good works: hospitals, homes, refuges, nursing societies, associations for assisting the young of both sexes and the like, for which Germany is conspicuous. But, on the other hand, in respect of faith evidences are less clear. Thus church-going is looked upon more as a duty to one's neighbour than as worship of God, and attendance on ordinary Sundays varies from 14 per cent. to a mere 2 per cent. of the population. Baptisms, marriages, and burials keep up their due proportion; there is only a slight falling off in confirmation (which must not be mistaken in any way for the English or Roman rite); but these things are so much required by law and system that they lose their voluntary character. The number of communicants, however, is seldom more than half of those entitled to receive the Holy Sacrament, even at great feasts; and it often goes below one-tenth. Of the communicants, men are fewer than women, being in some cases much less than one-third of the whole number.

See also PIEPER, *Kirchliche Statistik*, 1899.

(E. J. T.)

Luton, a municipal borough (extended 1896) and market town in the Luton parliamentary division of Bedfordshire, England, 30 miles north-north-west of London by rail. Modern erections are two churches, a Baptist and three Methodist chapels, a theatre, and a children's sick and convalescent home. There are public baths, a free library, and a technical school, supported by the town and county councils, and devoted partly to teaching the straw-plait industry. Electric light was installed in 1901, and in the same year a new sewage scheme was completed. Population on 2613 acres (1881), 23,960; (1891), on extended area of 3134 acres, 30,056; (1901), 36,404.

Lüttringhausen, a town of Prussia, in the Rhine province, 6 miles south-east of Elberfeld by rail. It is the seat of various iron and other metal industries, and cloth, calico, and silk mills. Population (1885), 10,216; (1900), 11,261.

Luxembourg, province of Belgium, bordering on Rhenish Prussia, the grand-duchy of Luxemburg, France, and the Belgian provinces of Namur and Liège. It comprises a part of the mediæval duchy of Luxemburg, which, under French domination (1795-1814), constituted the department des Forêts, and in 1815, under the title of the grand-duchy, was conferred on the prince of Orange, king of the Netherlands, and, lastly, in 1831 was divided into two parts—a western part forming the present province of the kingdom of Belgium, and an eastern part remaining, under the title of the grand-duchy of Luxemburg, in the possession of the House of Orange. In its entirety the most elevated of the provinces of Belgium, Luxemburg is in large part included in the region of the Ardeunes. It presents elevated plateaux of from 1300 to 2300 feet high, stretching towards the north-east; some wooded, others marshy or covered with

heath, and intersected by deep and picturesque valleys such as those of the Semois, the Lesse, the Ourthe, affluents of the Meuse, and of the Sure (in German, Sauer), an affluent of the Moselle. In general of scant fertility, the soil of the province is calcareous in the north, schistose in the zone of the Ardennes, calcareous, clayey, and sandy in the south. Its products are iron in small quantity and mauganese; slate, the quarrying of which employs 900 workmen; building, paving, and limestone. It rears the Ardennes horse, small in size, but very hardy. Of wild animals there are the boar, wolf, and deer. Woods cover 34 per cent. of the surface of the province. Its industry is not of much account. There are steel-works and blast-furnaces in the arrondissement of Arlon. Saw-mills and the making of wooden shoes employ 400 workers. The province is divided into five administrative arrondissements. The towns are of scant population. The principal are Arlon (8000), the capital; Bastogne (3600); and Marche (3600). This province has the largest extent of territory among the provinces of Belgium—1706 square miles—and is the least populated, having only 222,154 inhabitants in 1900, or 130 to the square mile. The arrondissement of Arlon has the densest population—259 inhabitants to the square mile. The population increased from 209,472 in 1875, that is, an increase of 5.1 per cent., against an increase of 25 per cent. in the same time in the whole kingdom.

Luxemburg, Grand-Duchy of, a neutral and independent state of Europe, bounded on the E. and N.E. by Prussia, S. by Alsace-Lorraine, and W. by the Belgian province of Luxembourg. It had in 1900 a population of 236,543 (of whom 122,002 were males and 114,541 females), showing a density of 237 persons to the square mile. The increase over the population in 1895 (18,960 in all) was exclusively in the mining districts, whereas in certain communes of the Ardennes there was an actual decrease. In 1900 the population included 14,240 Germans, 6700 Italians, 4250 Belgians, and 3500 French. All except about 1 per cent. are adherents of the Roman Catholic Church. The House of Representatives now consists of forty-five members, elected directly by the cantons, one-half every three years. The state revenue was in 1901 estimated at £483,960, and the expenditure at £498,880; and the public debt amounted to £462,420 in 1900. The state possesses 294 miles of railway, and 596 miles of telegraph line, with 1187 miles of wire. In 1899 the iron-mines (71 worked), blast-furnaces (28), and foundries (7) employed 10,600 work-people, and gave an output of 5,995,400 tons of iron ore, 982,930 tons of cast iron, and 166,210 tons of steel.

The Grand Duke, ADOLPHUS WILLIAM AUGUST CHARLES FREDERICK, was born at Biebrich 24th July 1817, succeeding his father as duke of Nassau 20th August 1839. He showed himself imbued with Liberal ideas, and skilfully steered his land through the troubles of the revolutionary period of 1848. In 1849 he took part in the campaign against Denmark at the head of a contingent. After the conclusion of this war he took a serious interest in German federal politics, and in the fateful year 1866 openly sided with Austria. As a result, the duchy of Nassau was annexed by Prussia, the duke unwillingly receiving a sum of about £1,275,000 as compensation for the loss of his dominions. Owing to the marriage of his daughter Hilda to the hereditary grand duke of Baden in 1885, his feud with the Prussian royal house may be said to have come to an end, and the *rapprochement* was finally sealed by a meeting with the Emperor William II. at Mainau in 1888. On the death of King William III. of the Netherlands on 23rd November 1890, Duke Adolphus, as nearest agnate of the House

of Orange, became reigning grand duke of Luxemburg. He was twice married: (a) to Elizabeth, daughter of the Grand Duke Michael of Russia, and (b) to Adelaide, daughter of Prince Frederick of Anhalt, by whom he had a son, William, born 22nd April 1852, who married Princess Anna of Braganza.

Luxemburg, or LÜTZELBURG, capital of the independent grand-duchy of the same name, and an episcopal see, 43 miles by rail north of Metz. The public institutions include an athenæum, a theological seminary, a collection of antiquities, a small picture-gallery, normal schools, a deaf and dumb asylum, a library, and an equestrian statue of Grand Duke William II. (1884). Amongst the industries may be mentioned tanneries, breweries, distilleries, glove, hat, tobacco, cotton, and linen factories. Population (1881), 17,964; (1900), 20,928.

Luxeuil-les-Bains, a French town in the arrondissement of Lure, department of Haute-Saône, 17 miles north-east of Vésoul, on the railway from Lure to Aillevillers, and on the Breuchin. It has a church dating from the 14th century, containing a curious 17th-century organ loft in the form of an immense bracket supported by a colossal figure of Hercules. There are also several mansions and houses dating from various periods from the 14th to the 16th century. The Maison Carrée, or Hôtel de Ville, an interesting specimen of 15th-century architecture, was built by the father of Cardinal Jouffray (died 1473), a native of the town. The fine modern Grammont Hospital is in the style of Louis XIII. Luxeuil is renowned for its mineral springs, of which there are eighteen, two being ferruginous, and the rest charged with chloride of sodium, yielding together about 14,000 gallons in the twenty-four hours, and of temperatures ranging from 70° to 156° Fahr. The water is employed for medicinal drinks and for baths. The bathing establishment is well appointed and stands in a fine park. Luxeuil, the ancient *Lixovium*, was frequented for bathing by the Romans, and contained many fine buildings at the time of its destruction by the Huns under Attila in 451. In 590 St Columban founded here a monastery, which rose rapidly to importance, but in the 8th century it was destroyed by the Saracens; afterwards rebuilt, monastery and town were again devastated by the barbarian hordes in the 9th century. In the 18th century the present bathing establishment was inaugurated by the ecclesiastics. Population (1881), 4153; (1901), 5294.

Luzon. See PHILIPPINE ISLANDS.

Luzzatti, Luigi (1841—), Italian economist and financier, was born at Venice on 11th March 1841. After completing his studies at Padua University, he attracted the attention of the Austrian police by his lectures on political economy, and was obliged to emigrate. In 1863 he obtained a professorship at the Milan Technical Institute, in 1867 was appointed professor of constitutional law at Padua, whence he was eventually transferred to the University of Rome. Gifted with eloquence and remarkable energy, he popularized in Italy the economic ideas of Schultze-Delitzsch, worked for the establishment of a commercial school at Venice, and, by indefatigable propaganda, contributed greatly to the spread of people's banks throughout the country. In 1869 he was appointed by Minghetti secretary-general of the ministry of agriculture and commerce, in which capacity he abolished Government control over commercial companies and promoted a state inquiry into the condition of industry. Though theoretically a free trader, he was largely instrumental in creating the Italian protective system. In 1877 he participated in the commercial negotiations with

France, in 1878 compiled the Italian customs tariff, and subsequently took a leading part in the negotiation of all the commercial treaties between Italy and other countries. Appointed Treasury minister in the first Rudini cabinet of 1891, he endeavoured to grapple with the difficult financial situation, but imprudently abolished the system of frequent clearings of bank-notes between the state banks, a measure which inadvertently facilitated the duplication of part of the paper currency and hastened the bank crisis of 1893. In 1896 he entered the second Rudini cabinet as Treasury minister, and by timely legislation helped to save the Bank of Naples from failure. After his fall from office in June 1898, his principal achievement was the negotiation of the Franco-Italian commercial treaty, though, as deputy, journalist, and professor, he continued to take an exceedingly active part in all the political and economic manifestations of Italian public life.

Lycaonia.—After the defeat of Antiochus the Great, Lycaonia was given by the Romans to Eumenes II., king of Pergamos. About 160 B.C. part of it, the "Tetrarchy of Lycaonia," was added to Galatia; and in 129 B.C. Lycaonia proper was given to Cappadocia as an eleventh strategia. In the readjustment of the Provinciae, 64 B.C., by Pompey after the Mithradatic wars, he gave the northern part of the tetrarchy to Galatia and the eastern part of the eleventh strategia to Cappadocia. The remainder was attached to Cilicia. In 371 Lycaonia was first formed into a separate province. It now forms part of the Konia vilayet.

See RAMSAY, *Historical Geography of Asia Minor. Historical Commentary on the Galatians.*

Lyck, or LYK, a town of Prussia, province of East Prussia, 112 miles by rail south-east of Königsberg, and close to the frontier of Poland, beside a lake of the same name. It is the chief town of the region known as Masuria, and has a new parish church and an old castle (on an island in the lake) of the Teutonic order, dating from 1273, but now used as a prison. The industries embrace iron foundries, distilleries, breweries, tanneries, paper mills, flour mills, &c. Population (1885), 8624; (1900), 11,419.

Lynchburg, a city of Virginia, U.S.A., on the south bank of the James river, at an altitude of 524 feet. Though within the limits of Campbell county, and containing the court-house, it is independent of county government. It is situated partly on the bottom-land of the river, and partly on the slopes and summit of the bluffs, which afford fine and commanding building sites for the many beautiful private residences of the city. The railways entering Lynchburg are the Southern, the Norfolk and Western, and the Chesapeake and Ohio. The manufactures are important and varied. Lynchburg has long been one of the chief points of tobacco manufacture, and iron manufacture has also become of great importance. The Norfolk and Western railway has works here. It is the seat of Randolph-Macon Women's College. Population (1890), 19,709; (1900), 18,891, of whom 251 were foreign-born and 8254 were negroes.

Lynmouth. See LYNTON.

Lynn, KING'S LYNN, or LYNN REGIS, a municipal borough, parliamentary borough (co-extensive, since 1885 returning only one member), market town, and seaport of Norfolk, England, on the Great Ouse, 97 miles north by west of London by rail. Modern erections are the Stanley Library and the municipal buildings. An inner dock was constructed in 1884. The harbour has an area of 30

acres, with an average depth of 10 feet. There is also good anchorage in the roads leading from the Wash to the docks. The registered shipping in 1888 consisted of 90 vessels of 7055 tons; in 1900, of 58 vessels of 3501 tons. In 1888, 1031 vessels of 146,669 tons entered and 1002 of 142,628 tons cleared; in 1900, 962 vessels of 224,869 tons entered and 980 of 226,854 tons cleared. In the latter year the imports (timber, minerals, coal, grain, and seeds) were valued at £1,141,867 and the exports at £130,469. Area, 3100 acres. Population (1881), 18,539; (1891), 18,360; (1901), 20,289.

Lynn, a city and seaport of Essex county, Massachusetts, U.S.A., on the north shore of Massachusetts Bay, 9 miles north-east of Boston, in the north-eastern part of the state. It is on a branch of the Boston and Maine railroad, and the Boston, Revere Beach, and Lynn railroad. The more closely built portions are on level ground, while the suburbs are rocky and broken. The plan is very irregular, the streets narrow and paved with macadam or gravelled, the water-supply is drawn from ponds in the neighbourhood by pumping, and the city is divided into seven wards. Lynn is chiefly known for its manufacture of boots and shoes, an industry to which the place is as completely devoted as Gloucester is to fishing, and, indeed, a large proportion of the footgear of the people of the United States is made here. The total number of manufacturing establishments in the city in 1900 was 776. They had a capital of \$17,011,761, employed 17,492 hands, and turned out products valued at \$41,633,845. There were 123 boot and shoe factories, with \$5,570,928 capital, 8652 hands, and products valued at \$16,830,733, besides 60 factories manufacturing cut stock for boots and shoes, which employed 1049 hands, and turned out products valued at \$7,385,106. There were also 12 leather factories, with a capital of \$1,031,025 and products valued at \$2,451,423. There were 3 factories for electrical apparatus and supplies, which employed 3166 hands and turned out products valued at \$5,840,668. The patent medicines and compounds manufactured were valued at \$1,338,833. The rocky, picturesque peninsula of Nahant, a part of Lynn, is a fashionable resort for the people of Boston and neighbouring cities, many of whom have summer homes there. The assessed valuation of real and personal property in 1900 was \$51,655,186, the net debt was \$3,632,398, and the rate of taxation \$18 per \$1000. Population (1890), 55,727; (1900), 68,513, of whom 17,742 were foreign-born and 784 were negroes. The death-rate was 16.4.

Lynn Canal, a noble fjord in Alaska, forming orographically a continuation of the trough of Chatham Strait, between 58° 12' and 60° N. Its width averages 6 miles, and its length about 100 miles. It is divided by islands near its entrance, and at the north by a long peninsula, named by Vancouver in 1793 Seduction Tongue. Its shores are for the most part mountainous, with numerous glaciers, of which Eagle, in 58° 30' N. on the east shore, and Davidson, in 59° 05' N. on the west, are the most important. Berners Bay, in 58° 40' N., indents the mainland shore, and is the seat of some mining operations. To the west of Seduction Tongue the fork of Lynn Canal is known as Chilkat Inlet. It receives at its head, over broad flats, the waters of the Chilkat river; and on its western extremity is a snug anchorage known as Pyramid Harbour, the seat of a salmon cannery. The valley of the Chilkat, inhabited by Indians of the same name, is the entrance to a practicable trail, known as the Dalton trail, to the Yukon, over which cattle are taken to the Klondike region. East of Seduction Tongue the fjord is continued as Chilkoot Inlet, and farther on as Taiya (Dyea) Inlet, terminating in two small

bays, Skagway and Taiya. These are the entrances to the two passes over the range to the head-waters of the Yukon, the White and the Chilkoot passes. The latter is the shorter and about 1000 feet higher. Wide flats make the access by water to Dyea less easy than to Skagway. A telpherage line was constructed in 1898 to carry goods over the summit, and many thousands of men and animals passed by this route over the range in 1896-99, bound for the Klondike. Now that Skagway has been connected by the Yukon and White Pass railway with Lake Bennett, all inward Klondike traffic passes by this route over the range. The principal settlements on Lynn Canal and its branches are Seward City, near Berners Bay; Pyramid Harbour; the Haines Mission at the northern end of Seduction Tongue; Skagway, and Dyea. The region is alpine in character, and subject to storms of extraordinary violence in winter, but not so cold that navigation is interrupted by ice at any time.

Lynton and Lynmouth, seaside villages of Devonshire, England, on the shore of the Bristol Channel, 17 miles by coach east of Ilfracombe, and 27 miles by railway north-east of Bideford. Lynmouth lies on the sea, at the mouth of the little rivers East Lyn and West Lyn, and Lynton stands on the edge of the cliffs, 430 feet above. The two are connected by a cliff railway or lift, and are lighted by electricity. The local improvements owe much to Sir George Newnes. A short distance up the Lyn is the picturesque Watersmeet, and the Doone Valley is not far off. Lynton is approached by a railway from Barnstaple. Population of Lynton (1901), 1641.

Lyons, the second town, in respect of population, of France, capital of the department of the Rhône, at the confluence of the Rhône and Saône, 311 miles from Paris by rail. Notwithstanding the competition of Milan, it is the chief silk market. In 1893 the special office which determines the weight and nature of the silk examined nearly 6000 tons of silk in 90,000 bales. France furnished barely one-tenth of this quantity; two-thirds came from China and Japan, the rest from Italy and the Levant. The traders of Lyons re-export seven-twelfths of these silks, the industries of the town employing the remainder. An almost equal quantity of cotton, wool, and waste-silk threads is mixed with the silk. A large proportion of the silk workers have left the town for its environs. Sixteen or seventeen thousand hand-loom are still worked in the town, more especially producing the richest materials, 50,000 or 55,000 in the surrounding districts, and 20,000 or 22,000 machine looms in the suburbs and environs. The total value of these looms is £4,000,000. Allied industries, such as dyeing, finishing, and printing, employ 12,000 workers. With the weavers, loom-builders, and other indispensable workers, 300,000 workpeople depend upon the silk industry. The value of the manufacture in 1899 was apportioned thus:—

Pure silk textures, plain	£5,028,000
do. do. figured	956,000
Textures of silk mixed with gold and silver, for the Levant	204,000
Textures of silk mixed with other materials, plain	4,714,000
Textures of silk mixed with other materials, figured	818,000
Textures of floss-silk and silk handkerchiefs	2,240,000
Coarse silk (<i>bourettes</i>) for furniture	60,000
Gauzes and grenadines	220,000
Crapes, summer shawls (<i>crêpes de Chine</i>), and muslins	2,260,000
Nets (tulle) and laces	880,000
<i>Passementerie</i>	640,000
Embroidery	20,000
Total	£18,040,000

In 1898 the total value was £16,600,000. The raw material represents half the value, and the value of the labour the remaining half. Thirty or forty per cent. of the silk goods of Lyons finds a market in France. Great Britain imports them to the value of £4,000,000, and the United States to the value of £2,400,000, notwithstanding the heavy duty. The dyeing industry and the manufacture of chemicals have both developed considerably to meet the requirements of the silk trade. The annual production of chemicals is as follows:—Mineral colouring matters, £240,000; vegetable colouring matters, £200,000; glue and gelatine, £240,000; superphosphates for manure, £240,000; phosphorus (the only French source of supply), £100,000; picric acid, £200,000; tartaric acid, £80,000; sulphuric and hydrochloric acids, sulphates of iron and copper, salts of soda, and manure, £680,000; pharmaceutical products, £240,000. Lyons does a large trade in metals, iron, and copper, and utilizes them in numerous workshops in the manufacture of iron buildings, framework, bridges, machinery, railway material, scales, metal cables, pins and needles, copper-founding, and the making of clocks and bronzes, the entire metallurgical industry employing 12,000 workmen and producing £3,000,000. Gold and silver working is of importance, especially for articles used in religious ceremonies. Other flourishing industries are those of printing, the manufacture of glass windows, the preparation of hides and skins (occupying 20,000 workmen), those connected with the miller's trade, the manufacture of various forms of dried flour-paste (macaroni, vermicelli, &c.), brewing, hat-making, the manufacture of chocolate, and the pork-butcher's industry. Apart from the railway traffic, the river traffic is important—in 1899 amounting to 600,000 tons on the Rhône and 725,000 tons on the Saône.

Lyons is the seat of important financial companies; of the *Crédit Lyonnais*, which does business to the amount of £200,000,000 annually in Lyons alone; also of coal and metallurgical companies and gas companies, the former extending their operations as far as Russia, the latter lighting numerous towns in France and foreign countries. There are several important technical schools, schools of weaving and industrial chemistry, and a school of the fine arts. Since 1870 the fortifications have been reconstructed, and form an entrenched camp 43 miles in circumference. The old wall of 1840, on the left bank of the Rhône, has been carried farther back. It describes a semicircle more than 7 miles long, which encloses the commune of Villeurbanne and part of the communes of Brou and Vénissieux. An iron bridge, 262 feet high and 655 feet long, will unite Fourvière and La Croix Rousse. Perhaps the most interesting modern enterprise has been the building of the new church of Fourvière. In 1872 it was begun, and in 1884 completed as regards the masonry, but its decoration was not finished until 1894. The total cost exceeded £320,000. The style recalls the Byzantine and Sicilian. It is flanked at each of the four corners by an octagonal tower, and ends in an apse shaped like a horse-shoe, surrounded by a porch which opens on the town to the east. From the *loggia* the archbishop of Lyons solemnly blesses the town on the 8th of September, the day of the Nativity of the Virgin. The 8th of December is also a *fête*, when all the streets are illuminated. The roof above the apse is surmounted by a colossal bronze group, 23 feet high, representing St Michael slaying the dragon. The towers are 159 feet high. The north-western is used as an observatory by the Free Faculty of Science. The north-eastern is furnished with a circular painting on lava, showing all the points visible on the horizon, with their distance and height. In clear weather a fine panorama of the Alps is visible from this tower.

The south-eastern tower contains a great bell weighing $6\frac{1}{2}$ tons, and the south-western, a carillon of thirteen bells. The church is 282 feet long from end to end, and 62 feet across the interior, and 88 feet high under the vaulting. A crypt, dedicated to St Joseph, and divided into three vaulted bays, extends under the church, which is built of magnificent materials and adorned on both the inside and outside with a profusion of marble and costly works of art. The high altar is of Carrara marble, supported by four angels; the mural decoration is of Venetian mosaic. In the park of Tête d'Or, a fine promenade, universal exhibitions were held in 1872 and 1894. Population (1886), 344,124; (1896), 398,867; (1901), 453,145.

Lyons, Richard Bickerton Pemell Lyons, 1ST EARL (1817–1887), British diplomatist, was the son of the first Baron Lyons, the celebrated admiral, and was born at Lymington, 26th April 1817. He entered the diplomatic service, and in 1858 became British minister at Washington, where, after the outbreak of the Civil War, the extremely important negotiations connected with the arrest of the Confederate envoys on board the British mail-steamer *Trent* devolved upon him. After a brief service at Constantinople, he succeeded Lord Cowley at the Paris embassy in 1867. In the war of 1870 he used his best efforts as a mediator, and accompanied the provisional government to Tours. He continued to hold his post with universal acceptance until November 1887, but succumbed to a paralytic stroke on 1st December 1887, the title becoming extinct.

Lyttelton, seaport, Selwyn county, Canterbury district, South Island, New Zealand, 5 miles south-east by east of Christchurch, with which it is connected by rail, on the inlet called Port Lyttelton, in the north side of Banks Peninsula. The harbour accommodation has been very much improved, and vessels of any size can anchor beside the wharves, where the depth of water is 26 feet. The harbour has an area of over 105 acres, and possesses a graving dock which can be entered by vessels of 6000 tons. The tonnage of shipping entered inwards in 1900 was 55,308; outwards, 118,333. The harbour board's receipts for 1899 were £32,392; expenditure, £36,859. The total trade for 1883 was £3,344,141; for 1893, £3,135,973; for 1900, £4,293,641. Population (1881), 4127; (1901), 4023.

Lytton, Edward Robert Bulwer-Lytton, 1ST EARL OF (1831–1891), English diplomatist and poet, was the only son of the first Baron Lytton (*Ency. Brit.* vol. xv. p. 121). He was born in Hertford Street, Mayfair, on 8th November 1831. Robert Lytton and his sister were brought up as children principally by a Miss Green. In 1840 the boy was sent to a school at Twickenham, in 1842 to another at Brighton, and in 1845 to Harrow. From his earliest childhood Lytton read voraciously and wrote copiously, quickly developing a genuine and intense love of literature and a remarkable facility of expression both in prose and verse. His letters to his father from school show maturity of thought and of style unusual at that age, and his wish at this period was to devote his life to literary studies and the production of poetry. He had little taste for the ordinary amusements of boyhood, and obtained no scholastic distinction. In 1849 he left Harrow, and studied for a year at Bonn with an English tutor, and on his return with another tutor in England. In 1850 he entered the diplomatic service as unpaid *attaché* to his uncle, Sir Henry Bulwer, who was then minister at Washington. His advance in the diplomatic service was continuous, his successive appointments being: as second secretary—1852, Florence (under Lord Normanby); 1854, Paris (Lord Cowley); 1857, The Hague; 1859, Vienna (Lord Bloomfield); as

first secretary or secretary of legation—1863, Copenhagen (Sir A. Paget); 1864, Athens (Mr Erskine); 1865, Lisbon (Sir A. Magennis); 1868, Madrid; 1868, Vienna; 1873, Paris (Lord Lyons); as minister—1875, Lisbon. In 1887 he was appointed to succeed Lord Lyons as ambassador at Paris, and held that office until his death in 1891. This rapid promotion from one European court to another for a period of twenty-three years indicates the esteem in which Lytton was held by successive foreign secretaries. In 1864, immediately before taking up his appointment at Athens, he married Edith, daughter of Edward Villiers, brother of the earl of Clarendon, and in 1873, upon the death of his father, he succeeded to the peerage and the estate of Knebworth in Hertfordshire, devised to his father by his grandmother, the last heiress of the family of Lytton.

Early in 1875 Lord Lytton declined an offer of appointment as governor of Madras, and in November of that year he was nominated governor-general of India by his father's old friend and colleague, Mr Disraeli. The moment was critical in the history of India. Disraeli, securely established in power for the first and last time, was set upon reversing the tradition of the preceding ten years, and proving to the world that Great Britain was not afraid either of imperial greatness or international responsibility. In Central Asia the advance of Russia had continued so steadily and so rapidly that Sher Ali, the Amir of Afghanistan, had determined to seek safety as the vassal of the Tsar as quickly as circumstances should permit. Lytton went out to India with express instructions from the British Government to recover the friendship of the Amir if possible, and if not so to arrange matters on the North-West frontier as to be able to be indifferent to his hostility. For eighteen months Lytton and his Council made every effort to conciliate the friendship of the Amir, but when a Russian agent was established at Kabul, while the mission of Sir Neville Chamberlain was forcibly denied entrance into the Amir's dominions, no choice was left between acknowledging the right of a subsidized ally of Great Britain to place himself within Russian control and depriving him of the office which he owed to British patronage and assistance. The inevitable war began in November 1878, and by the close of that year the forces prepared by Lytton for that purpose had achieved their task with extraordinary accuracy and economy. Sher Ali fled from Kabul, and shortly afterwards died, and once more it fell to the Indian Government to make provision for the future of Afghanistan. By the treaty of Gundamak in May 1879 Yakub Khan, a son of Sher Ali, was recognized as Amir, the main conditions agreed upon being that the districts of Kuram, Pishin, and Sibi should be "assigned" to British administration, and the Khyber and other passes be under British control; that there should be a permanent British Resident at Kabul, and that the Amir should be subsidized in an amount to be afterwards determined upon. The endeavour of the Indian Government was to leave the internal administration of Afghanistan as little affected as possible, but considerable risk was run in trusting so much, and especially the safety of a British envoy, to the power and the goodwill of Yakub Khan. For the conclusion of this treaty Lytton received the thanks of both Houses of Parliament in August of the same year. Sir Louis Cavagnari, the British envoy, entered Kabul at the end of July, and was, with his staff, massacred in the rising which took place on the 3rd September. The war of 1879–80 immediately began, with the occupation of Kandahar by Stewart and the advance upon and capture of Kabul by Roberts, and the military operations which followed were not concluded when Lytton resigned his office in April 1880.

A complete account of Lytton's viceroyalty, and a lucid exposition of the principles of his government and the main outlines of his policy, may be found in *Lord Lytton's Indian Administration*, by his daughter, Lady Betty Balfour (London, Longmans, 1899). The frontier policy which he adopted, after the method of a friendly and united Afghanistan under Yakub Khan had been tried and had failed, was that the Afghan kingdom should be destroyed. The province of Kandahar was to be occupied by Great Britain, and administered by a vassal chief, Sher Ali Khan, who was appointed "Wali" with a solemn guarantee of British support (unconditionally withdrawn by the Government succeeding Lytton's). The other points of the Indian frontier were to be made as secure as possible, and the provinces of Kabul and Herat were to be left absolutely to their own devices. In consequence of what had been said of Lytton by the leaders of the Parliamentary Opposition in England, it was impossible for him to retain his office under a Government formed by them, and he accordingly resigned at the same time as the Beaconsfield ministry. This part of his policy was thereupon revoked. Abdur Rahman, proving himself the strongest of the claimants to the throne left vacant by Yakub Khan's deposition, became Amir as the subsidized ally of the Indian Government.

The two most considerable events of Lytton's viceroyalty, besides the Afghan wars, were the assumption by Queen Victoria of the title of Empress of India on the 1st January 1877, and the famine which prevailed in various parts of India during the same year. The Durbar at Delhi, at which the Queen was proclaimed empress, was the dramatic completion of the transfer of the Indian government in 1858 from the East India Company to the sovereign of the United Kingdom. It was a pageant of unprecedented splendour, and at the same time a gathering of more or less dependent native princes and chiefs such as had never previously been held. To the famine of 1876-78 Lytton devoted a great part of his time and thoughts. Having personally witnessed in different parts of India the application of the methods then adopted for dealing with such a catastrophe, he satisfied himself that periodical famines must be expected in Indian history, and that constant preparation during years of comparative prosperity was the only condition whereby their destructiveness could be modified. Accordingly he proposed and obtained the appointment of the Famine Commission of 1878, to inquire, upon lines laid down by him, into available means of mitigation. Their report, made in 1880, is the foundation of the later system of irrigation, development of communications, and "famine insurance." The equalization and reduction of the salt duty were effected, and the abolition of the cotton duty commenced, during Lytton's term of office, and the system of Indian finance profoundly modified by decentralization and the regulation of provincial responsibility, in all which matters Lytton enthusiastically supported Sir John Strachey, the financial member of his Council.

Upon Lytton's resignation in 1880 an earldom was conferred upon him in recognition of his services as viceroy. He returned home, and lived at Knebworth until 1887, in which year he was appointed to succeed Lord Lyons as ambassador at Paris. For this great office it was considered that his wide knowledge of European diplomacy and remarkable command of the French language gave him altogether exceptional qualifications, and the general expectation of his success was not disappointed. British diplomatic relations with France were never on a more thoroughly satisfactory footing than during the four years of Lytton's embassy. They were the last years of his life. He died at Paris on 24th November 1891, of a clot of

blood in the heart, when apparently recovering from a serious illness.

Lytton is probably better known as a poet—under the pen-name of "Owen Meredith"—than as a statesman. The list of his published works is as follows: *Clytemnestra, and other Poems*, 1855; *The Wanderer*, 1858; *Lucile*, 1860; *Serbski Pesme, or National Songs of Servia*, 1861; *Tannhäuser* (in collaboration with Mr Julian Fane), 1861; *Chronicles and Characters*, 1867; *Orval, or The Fool of Time*, 1868; *Fables in Song* (2 vols.), 1874; *Glenaveril, or The Metamorphoses*, 1885; *After Paradise, or The Legends of Exile, and other Poems*, 1887; *Marah*, 1892; *King Poppy*, 1892. The two last-mentioned volumes were published posthumously. A few previously unpublished pieces are included in a volume of *Selections* published, with an introduction by Lady Betty Balfour, in 1894 (Longmans and Co.). His metrical style was easy and copious, but not precise. It often gives the impression of having been produced with facility, because the flow of his thought carried him along, and of not having undergone prolonged or minute polish. It was frequently suggestive of the work of other poets, especially in his earlier productions. The friend who wrote the inscription for the monument to be erected to him at St Paul's described him as "a poet of many styles, each the expression of his habitual thoughts." *Lucile*, a novel in verse, presents a romantic style and considerable wit; and *Glenaveril*, which also contains many passages of great beauty and much poetic thought, has much of the same narrative character. Beside his volumes of poetry, Lytton published in 1883 two volumes of a biography of his father. The second of these contains the beginning of the elder Lytton's unfinished novel, *Greville*, and his life is brought down only to the year 1832, when he was twenty-six years of age, so that the completion of the book upon the same scale would have required at least four more volumes. The executrix of Lytton's mother chose to consider that the publication was injurious to that lady's memory, and issued a volume purporting to contain Bulwer-Lytton's letters to his wife. This Lytton suppressed by injunction, thereby procuring a fresh exposition of the law, that the copyright in letters remains in the writer or his representatives, though the property in them belongs to the recipient. Lytton's appointment to the Parisian embassy caused the biography of his father to be finally laid aside.

Lytton was physically well-proportioned, delicately made, and rather below than above the average size. He had no aptitude for outdoor sports, and was probably at no time robust in health or given to any considerable bodily activity. As a young man he was extremely handsome, his head being well-shaped and thickly covered with closely curling hair, which he retained all his life. In middle age the marked characteristics of his features were intelligence and extreme vitality. His ordinary conversation arrested notice at once by its humour, its wide comprehensiveness, its flexibility, and its startling candour. But in business matters the vigour and swiftness of his intellect were what most distinguished him. The promptness with which he seized and mastered the essential points of the matter under discussion, and the incisive force with which his own view of it was expressed, demonstrated at once and without question that he was a man of the highest ability. With a strong regard for all the conventions of life as such, he entirely refused to govern his conduct by those which he conceived not to be applicable to himself, and there were people who resented this side of his character. His dress, without being startling, was usually distinctive, and his choice of clothes in private life was regulated principally by a regard for his own comfort. He would address any one, in any station of life,

for whom he felt a regard, as "dear —," and both in conversation and in correspondence made far more frequent use of the superlative "dearest" than is at all usual in England. Though he had considerable eloquence, his main methods of expression were conversation and writing. His prose style was extraordinarily lucid and powerful,

but his minutes and despatches were very seldom short. During the interval between his Indian government and his embassy at Paris he lived at Knebworth, where, out of filial affection, he preserved sedulously much of his father's embellishment of the house, and added considerably to the fabric. (H. S*.)

Maasin, a town on the coast in the extreme south-western portion of the island of Leyte, Philippine Islands. It is an important port for the shipment of abacá (*Musa textilis*), and the low, fertile plains in its vicinity also produce cotton, pepper, tobacco, and rice in considerable quantities. It is the only point on the western coast of Leyte where a court of justice is held. The language is Visayan. Population, 18,000.

Macao, a Portuguese possession, situated near the estuary of the Canton river, China. During the south-west (summer) monsoon great quantities (67 inches) of rain fall, especially in July and August. The mean temperature is 74.3° Fahr.; in July, the hottest month, the temperature is 84.2°; in February, the coldest, it is 59°. On the whole the climate is moist. Hurricanes are frequent. Its area is 4 square miles. Population (1896), Chinese, 74,568; Portuguese, 3898; and other nationalities, 161—total, 78,627. Of the Portuguese more than three-fourths were natives of Macao—a race very inferior in point of physique to their European ancestors. Macao is connected with the colony of Hong-Kong by a daily steamer. Being open to the south-west sea breezes, it is a favourite place of resort from the oppressive heat of Hong-Kong. It is ruled by a governor, and, along with Timor (East Indies), constitutes a bishopric, to which belong also the Portuguese Christians in Malacca and Singapore. There are a lyceum, seminary, and college (Santa Rosa de Lima). Silks, mats, tobacco, paper, preserved foods, rugs, timber, opium, and goldsmiths' work are the principal articles manufactured or prepared. The trade, mostly transit and in Chinese hands, increased in value from £2,259,250 in 1880 to £3,771,615 in 1898, the commodities mostly dealt in being opium, tea, rice, oil, raw cotton, fish, and silk. Macao is hardly of any account, however, as a port of foreign trade. In fishing 920 boats and 8700 men and boys are employed. Fish was exported to the value of £882,200 in 1895.

Although Macao is, *de facto*, a colonial possession of Portugal, the Chinese Government persistently refused to recognize the claim of the Portuguese to territorial rights, alleging that they were merely lessees or tenants at will. This diplomatic difficulty prevented the conclusion of a commercial treaty between China and Portugal for a long time, but an arrangement for a treaty was come to in 1887 on the following basis:—(1) China confirmed perpetual occupation and government of Macao and its dependencies by Portugal. (2) Portugal engaged never to alienate Macao and its dependencies without the consent of China. (3) Portugal engaged to co-operate in opium revenue work at Macao in the same way as Great Britain at Hong-Kong. The formal treaty was signed in the same year, and arrangements were come to whereby the Chinese Imperial Customs were able to collect duties on vessels trading with Macao in the same way as they had already arranged for their collection at the British colony of Hong-Kong.

Macarsca (also spelt *Makaraska*), a seaport town in the Austrian crownland of Dalmatia, opposite the island of Brazza, and about 32 miles south-east of Spalato. Some of the best Dalmatian wine is grown in the district, and the town has a considerable trade in corn, figs, and other fruit. It is a station of the Austrian Lloyd. In 1890 it had a population of 10,309, and in 1900, 11,016, chiefly Serbo-Croatian.

Macassar. See CELEBES.

M'Carthy, Justin (1830—), Irish politician,

historian and novelist, was born in Cork, 22nd November 1830, and was educated at a school in that town. He began his career as a journalist at the age of eighteen, in Cork. From 1853 to 1859 he was in Liverpool, on the staff of the *Northern Daily Times*, during which period he married (in March 1855) Miss Charlotte Allman. In 1860 he removed to London, as parliamentary reporter to the *Morning Star*, of which he became editor in 1864. In 1868 he gave up this post, and, after a lecturing tour in the United States, joined the staff of the *Daily News* as leader-writer in 1870. He lectured again in America in 1870–71, and again in 1886–87. He represented Co. Longford in Parliament as a Liberal and Home Ruler from 1879 to 1885; North Longford, 1885–86; Londonderry, 1886–92; and North Longford from 1892 to 1900. He was chairman of the Anti-Parnellites from the fall of Mr Parnell in 1890 until January 1896; but his Nationalism was of a temperate and orderly kind, and though his personal distinction singled him out for the nominal chairmanship he was in no sense the political leader. His real bent was towards literature. His earliest publications were novels, some of which, such as *A Fair Saxon* (1873), *Dear Lady Disdain* (1875), *Miss Misanthrope* (1878), *Donna Quixote* (1879), attained considerable popularity. His most important work is his *History of Our Own Times* (vols. i.–iv. 1879–80; vol. v. 1897), which treats of the period between Queen Victoria's Accession and her Diamond Jubilee. Easily and delightfully written, these volumes form a brilliant piece of narrative from a Liberal standpoint. He also started on a *History of the Four Georges* (1884–1901), of which the latter half was written by his son, Justin Huntly M'Carthy (born 1860), who is the author of various novels, plays, and short histories. Justin M'Carthy, amongst other works, wrote biographies of Sir Robert Peel (1891), Pope Leo XIII. (1896), and W. E. Gladstone (1898), and published his *Reminiscences*, in 2 vols., in 1899.

McClellan, George Brinton (1826–1885), soldier and author, was born in Philadelphia, Pa., 3rd December 1826. After passing two years (1840–42) in the University of Pennsylvania, he entered the U.S. military academy, from which he graduated with high honours, July 1846. Sent as a lieutenant of engineers to the Mexican war, he took part in the battles under General Scott, and won brevets of first lieutenant and captain for gallantry; he was afterwards detailed as assistant-instructor at West Point, and upon explorations at the south-west and in Oregon. Promoted in 1855 to captain of cavalry, he served on a military commission sent to Europe to study the Crimean war, and furnished an able and interesting report. Resigning his commission in 1857, McClellan became successively chief engineer and vice-president of the Illinois Central railroad (1857–60) and president of the St Louis and Cincinnati railroad, with his residence in Cincinnati. When the Civil War broke out, he was, in April 1861, made major-general of three months' militia by the governor of Ohio; but General Scott's favour at Washington promoted him rapidly, 14th May, to major-general, U.S.A., with a military department north of the Ohio river. Pursuant to orders, 26th May, McClellan sent a small force across the Ohio river to Philippi, dispersed the Confederates there in early

June, and aided immensely the movement of the Unionist forces in that region by rapid and brilliant military successes, gained, 11th to 13th July, with Rosecrans next in command, at Rich Mountain and Carrick's Ford. These operations, though comparatively trivial as the Civil War developed, brought great results, in permanently dividing old Virginia, by the erection of the loyal state of West Virginia, and in presenting the first sharp, short, and wholly successful campaign of the war. Soon after the Bull Run disaster, he was summoned to Washington, and the Union hailed him as chieftain and preserver. Only thirty-four years old, and with military fame and promotion premature and quite in excess of positive experience, he reached the capital, 26th July, and assumed command. At first all was deference and compliance with his wishes. The veteran Scott retired that this young hero might have the operations of the whole Union within his closer control. McClellan proved himself a grand organizer, and created that famous army of the Potomac, which idolized him with the devotion of a first faith. But he soon showed petulance towards the civil authorities, from whom he came to differ concerning the political ends in view. His army grew rapidly in numbers and discipline but did not go forward. Autumn and winter passed, and nothing was done until the spring of 1862. McClellan now found severe critics who doubted his capacity for the aggressive; but the Government yielded to his plans for an oblique instead of direct movement upon Richmond and the opposing army. By 5th April his invading column of 121,500 was safely transported to Fortress Monroe, and other troops were sent later at his earnest request, some being retained to cover Washington. McClellan laid slow siege to Yorktown, not breaking the thin line first opposed to him, but giving Johnston full time to reinforce and then evacuate. Next at Williamsburg, 5th May, came an undirected battle, accidentally brought on during his pursuit. Richmond was in danger; but McClellan had made the York rather than the James river his line of approach, and with White House Landing for a base of supplies, he found himself compelled to divide his immense force by the malarial stream of the Chickahominy. At "Seven Pines" (or "Fair Oaks") was fought, 31st May, a bloody battle, ending the following day in a Confederate repulse. Johnston being severely wounded, Lee came to command on the southern side. Long storms now hindered operations, until, with a newly recruited army, Lee despatched two-thirds of his entire force to the north of the Chickahominy to strike McClellan's isolated right wing. The Seven Days' Battles began 26th June, with Lee's assault strenuously resisted by General Fitz-John Porter at Mechanicsville, and then at Gaines's Mill, after which, on the night of the 27th, McClellan announced his purpose to transfer his base to the James river. This change was promptly executed in a masterly manner, but at Glendale and Malvern Hill fierce battles were fought, and all was retreat, without effort to outflank Lee or move by the inner line upon Richmond. Operations nearer Washington having changed the theatre of conflict, General Halleck, who was now general-in-chief, ordered McClellan and his army back from the peninsula to reinforce General Pope in the region of Manassas. The order was obeyed reluctantly. Pope's disastrous defeat (29th and 30th August) brought McClellan a new opportunity to retrieve his fame, for President Lincoln, against the earnest remonstrance of Stanton and others of his cabinet, now placed him once more in command, and sent him to oppose Lee, who crossed the Potomac into Maryland in early September. At Antietam, on the 17th, was fought a great battle, in which Lee was worsted, McClellan having profited by an order which

fell into his hands, disclosing his enemy's whole plan of invasion. But the Confederates safely recrossed the Potomac, and McClellan showed his former faults in a tardy pursuit and aggression. Having by 7th November reached the full limit of experiment, President Lincoln now superseded McClellan in command of the army of the Potomac. McClellan was never again ordered to active command, and the political elements opposed to the general policy of this administration united on him for President in 1864, on a platform which denounced the war as a failure and proposed negotiating with the South for peace. McClellan, while accepting his candidacy, repudiated the platform, like a soldier and patriot. At the polls, 8th November, Lincoln was triumphantly re-elected President. On the day of election McClellan resigned his high commission in the army, and soon afterwards went to Europe, where he remained until 1868. Upon his return he took up his residence in New York City, where (1868-69) he engaged in superintending the construction of an experimental floating battery. In 1870-72 he was engineer-in-chief of the city's department of docks. With Orange, N.J., next as his principal residence, he became Democratic governor of New Jersey (1878-81). During his last years he made several tours of Europe, visited the East, and wrote much for the magazines. He also prepared monographs upon the Civil War, defending his own action. He died suddenly at Orange, of heart disease, 29th October, 1885.

McClellan was a clear and able writer and effective speaker, and his *Own Story*, edited by a friend and published soon after his death, discloses an honourable character, sensitive to reproach, and conscientious, even morbidly so, in his patriotism. He carried himself well while in civil station and was of irreproachable private conduct. During the Civil War, however, he was promoted too early and rapidly for his own good, and the strong personal magnetism he inspired while so young developed an inordinate self-esteem and exaltation, injurious to a full measure of success and usefulness, despite his splendid opportunities. The reasons for his final displacement in 1862 were both civil and military, and the President had been forbearing with him. As a soldier McClellan was a marvellous organizer and moulder of the raw material of an army, and could inspire those under him to fight. But he was slow and feeble, perhaps too tender-hearted, in handling armed masses for action; and though admirable for defensive war and a safe strategist, he showed himself unfitted to take the highly essential initiative, both because of temperament and his habitual exaggeration of obstacles and opposing numbers. (J. SCH.)

Macclesfield, a municipal borough and market town in (since 1885) the Macclesfield parliamentary division of Cheshire, England, on the river Bollin, 17 miles south by east of Manchester by rail. The County Lunatic Asylum has been enlarged to accommodate epileptic patients, and in 1894 the town was presented with the Victoria Park (13 acres). There is a technical school. "Macclesfield Forest" is now nearly treeless. Hand-loomers are still largely used in the silk-throwing mills. Population (1881), 37,514; (1901), 34,635. The parish of SUTTON stretches 4 miles south-south-east of the town, and is partly contained in the municipal borough.

M'Clintock, Sir Francis Leopold (1819—), Arctic explorer, was born at Dundalk in 1819. He entered the navy at the age of twelve, and spent some fifteen or sixteen years on foreign service. His first experience of Arctic travel was gained on H.M.S. *Enterprise*, in an expedition despatched by the Admiralty in 1848, at the time when the greatest anxiety was entertained concerning the fate of Sir John Franklin's

expedition. In 1850 he served with a similar expedition, on H.M.S. *Assistance*, and in the summer of that year saw, at Cape Riley, some traces of the lost explorers. In the following spring he made a sledge journey of 760 miles, and reached the most westerly point then explored in the Arctic. On his return, in 1851, he was promoted to the rank of commander, and in 1852 returned to the Arctic in command of H.M.S. *Intrepid*, one of five vessels sent in that year to continue the search for Franklin. This time he was away for two years, in the course of which he distinguished himself by another long sledge journey of exploration, and by the discovery and rescue of a body of explorers who, under Captain McClure, had been missing for three years. In 1857, having now reached the rank of captain, he took command of the search expedition equipped by Lady Franklin, and, in the ship *Fox*, succeeded in discovering on the shore of King William Land a record of the death of Sir John Franklin and the fate of his men and ships. For his services in this connexion he was knighted (in 1859), and received the freedom of the City of London as well as marks of honour from various universities. From 1859 to 1865 he was on foreign service, and from 1865 to 1868 was commodore at Jamaica. From 1868 to 1871 (when he was promoted to rear-admiral) he was a naval aide-de-camp to Queen Victoria; from 1872 to 1877 admiral superintendent of Portsmouth dockyard; after which, reaching the rank of vice-admiral, he served as commander-in-chief of the North American and West Indian station from 1879 to 1882. In 1884 he retired as full admiral, and became an elder brother of the Trinity House. In 1887 he was awarded a special pension for his services, and was created K.C.B. in 1891. He published, in 1859, his narrative of his search for Sir John Franklin, under the title of *The Voyage of the "Fox"*; it reached a fifth edition in 1881. He married, in 1870, Annette Elizabeth Dunlop.

Mac Cormac, Sir William, BART. (1836–1901), Irish surgeon, was born at Belfast, 17th January 1836, being the son of Dr Henry Mac Cormac. He was educated in medicine and surgery at Belfast, Dublin, and Paris, and graduated in arts, medicine, and surgery at the Queen's University of Ireland, in which he afterwards became an examiner in surgery. He started practice in Belfast, where he became surgeon to the General Hospital, but left it for London on his marriage in 1861 to Miss Katherine M. Charters. In the Franco-German war of 1870 he was surgeon-in-chief to the Anglo-American Ambulance, and was present at Sedan; and he also went through the Turco-Servian war of 1876. He became in this way an authority on gun-shot wounds, and besides being highly successful as a surgeon was very popular in society, his magnificent physique and Irish temperament making him a notable and attractive personality. In 1881 he was appointed assistant-surgeon at St Thomas's Hospital, London, and for twenty years continued his work there as surgeon, lecturer, and consulting surgeon. In 1881 he acted as hon. secretary-general of the International Medical Congress in London, and was knighted for his services. In 1883 he was elected member of the Council of the College of Surgeons, and in 1887 a member of the Court of Examiners; in 1893 he delivered the Bradshaw lecture, and in 1896 was elected president, being re-elected to this office in 1897, 1898, 1899, and 1900 (the centenary year of the College), an unprecedented record. In 1897 he was created a baronet, and appointed surgeon-in-ordinary to the prince of Wales; and in 1898, in recognition of his attendance on the prince at the time of an accident to H.R.H.'s knee-cap, he was made K.C.V.O. His foreign distinctions and orders were also numerous. In 1899 he was

Hunterian Orator. In the same year he volunteered to go out to South Africa as consulting surgeon to the forces, and from November 1899 to April 1900 he saw much active service both in Cape Colony and Natal, his assistance being cordially acknowledged on his return. In 1901 he was appointed honorary serjeant-surgeon to the King. But during 1898 he had suffered from a prolonged illness, and he had perhaps put too much strain on his strength, for on 4th December 1901 he died somewhat suddenly at Bath. Besides treatises on *Surgical Operations* and *Antiseptic Surgery*, and numerous contributions to the medical journals, Sir William Mac Cormac was the author of *Work under the Red Cross* and of an interesting volume commemorating the centenary of the Royal College of Surgeons in 1900. The latter contains biographical notices of all the masters and presidents up to that date. (H. CH.)

McCormick, Cyrus Hall (1809–1884), American inventor of grain-harvesting machinery, was born at Walnut Grove, Rockbridge county, Va., U.S.A., 15th February 1809. His father was a farmer who had invented numerous labour-saving devices for farm work, but after repeated efforts had failed in his attempts to construct a successful grain-cutting machine. In 1831, Cyrus, then twenty-two years old, took up the problem, and after careful study constructed a machine which was successfully employed in the late harvest of 1831 and patented in 1834. The McCormick reaper came into use slowly for many years, but after further improvements proved a complete success; and in 1847 the inventor removed to Chicago, where he established large works for manufacturing his agricultural machines. William H. Seward has said of McCormick's invention, that owing to it "the line of civilization moves westward thirty miles each year." Numerous prizes and medals were awarded for his reaper, and he was elected a corresponding member of the French Academy of Sciences, "as having done more for the cause of agriculture than any other living man." He died in Chicago, 13th May 1884.

M'Cosh, James (1811–1894), educator and philosophical writer, was born at Carskeoch, in Ayrshire, on the 1st of April 1811. He studied at Glasgow and Edinburgh, receiving at the latter his M.A., at the suggestion of Sir William Hamilton, for an essay on the Stoic philosophy. He became a minister of the Established Church of Scotland, and took part in the Free Church movement of 1843. In 1852 he was appointed professor of logic and metaphysics in Queen's College, Belfast; and in 1868 was chosen president of the College of New Jersey, at Princeton, a post which he filled with much acceptance until his resignation in 1888. The list of his philosophical, religious, and controversial (against Mill, Huxley, and Tyndall, in particular) writings began with *The Method of the Divine Government, Physical and Moral* (1850), which was cordially received by conservative theologians, and ended with *The Religious Aspects of Evolution* (1888). His general philosophical attitude and method were Hamiltonian; he insisted on severing religious and philosophical data from merely physical; and though he added little to original thought, he clearly restated and vigorously used the conclusions of others. He died at Princeton on the 16th of November 1894. (C. F. R.)

M'Culloch, Sir James (1819–1893), Australian statesman, son of George M'Culloch, was born in Glasgow in 1819. He entered the house of Dennistoun Brothers, became a partner, and went to Melbourne to open a branch. In 1854, shortly after his arrival in Victoria, he was appointed a nominee member of the Legislative Council, and in the first Legislative Assembly under the new con-

stitution was returned for the electorate of the Wimmera. In 1857 he was appointed Minister of Trade and Customs in the second ministry of Mr Haines, which lasted till 1858, and subsequently, while representing East Melbourne, he became Treasurer in the Nicholson administration, which held office from October 1859 to November 1860. After its resignation Mr M'Culloch revisited Europe, and on his return to Victoria he re-entered the Assembly as member for Mornington. In June 1862 the third O'Shanassy ministry was defeated by a combination between a section of its supporters led by Mr M'Culloch and the Opposition proper under Mr Heales, and Mr M'Culloch became Premier and Chief Secretary. Hitherto he had been regarded as a Conservative, and a supporter of the landed, squatting, and importing interests, but the coalition ministry introduced a number of measures which at the time were regarded by the propertied classes in the colony as revolutionary. In addition to passing a land Bill, which extended the principle of free selection and deferred payments, the ministry announced their intention of reducing the duties on the export of gold and the import duties upon tea and sugar, and of supplying the deficiency by the imposition of duties ranging from 5 to 10 per cent. upon a number of articles which entered into competition with the local industries, thus introducing protection. The mercantile community took alarm at the proposal, and at the general election of 1864 the ministerial policy was warmly opposed. But a majority was returned in its favour, and a new tariff was carried through the popular branch of the Legislature. There was no probability of its being assented to by the Council, which, under the constitution, had the power of rejecting, although it could not amend, any money Bill. The Government therefore decided upon tacking the tariff to the Appropriation Bill, and compelling the Council either to agree to the new fiscal proposals or to refuse to pay the public creditors and the civil servants. The Council accepted the challenge, and rejected the tacked Appropriation Bill. But Mr M'Culloch and his colleagues would not give way. They continued to collect the new duties under the authority of the Assembly, and took advantage of a clause in the Audit Act which directed the Governor to sign the necessary warrants for the payment of any sum awarded by verdicts in the Supreme Court in favour of persons who had sued the Government. Mr M'Culloch borrowed £40,000 from the London Chartered Bank, of which he was a director, to meet pressing payments, and the bank at his instigation sued the Government for the amount of the advance. The Attorney-General at once accepted judgment, and the Governor, who had placed himself unreservedly in the hands of his ministers, signed the necessary warrant, and the Treasury repaid to the bank the amount of its advance, plus interest and costs. In the next session of Parliament the tariff was again sent up to the Council, which promptly rejected it, whereupon the ministry dissolved the Assembly and appealed to the country. The result of the general election was to increase Mr M'Culloch's majority, and the tariff was again sent to the Council, only to be again rejected. Mr M'Culloch resigned, but no member of the Opposition was willing to form a ministry, and he resumed office. Eventually a conference between the two Houses was held, and the Council passed the tariff, after a few modifications in it had been agreed to by the Assembly. Just at the moment that peace was restored, the Governor, Sir Charles Darling, was recalled by the Home Government, on the ground that he had displayed partisanship by assisting Mr M'Culloch's Government and their majority in the Assembly to coerce the Council. In order to show their gratitude to the dismissed Governor, the Assembly de-

ecided to grant a sum of £20,000 to Lady Darling. The Home Government intimated that Sir Charles Darling must retire from the Colonial service if this gift were accepted by his wife, but Mr M'Culloch included the money in the annual Appropriation Bill, with the result that it was rejected by the Council. The new Governor, Viscount Canterbury, was less complaisant than his predecessor, but after an unsuccessful attempt to obtain other advisers, his Excellency agreed to recommend the Council to pass the Appropriation Bill with the £20,000 grant included. The Upper House declined to adopt this course, and again rejected the Bill. A long and bitter struggle between the two Chambers ended in another general election in 1868, which still further increased the ministerial majority; but Lord Canterbury, in obedience to instructions from the Colonial Office, declined to do anything to facilitate the passage of the Darling grant. Mr M'Culloch resigned, and after protracted negotiations Sir Charles Sladen formed from the minority in the Assembly a ministry which only lasted two months. The deadlock seemed likely to become more stringent than ever, when a communication was received from Sir Charles Darling, that neither he nor his wife could receive anything like a donation from the people of Victoria. The attempt to pass the grant was therefore abandoned, and in July 1868 Mr M'Culloch resumed office with different colleagues, but resigned in the following year, when he was knighted. He formed a third ministry in 1870. During this third administration he passed a measure through both Houses which secured a life annuity of £1000 per annum to Lady Darling. Additional taxation being necessary, Sir James M'Culloch was urged by his protectionist supporters to increase the import duties, but he refused, and proposed to provide for the deficit by levying a tax upon town, suburban, and country property. This proposal was defeated in the Assembly; Sir James resigned in June 1871, and was appointed Agent-General for Victoria in London. He held that appointment till 1873, was created K.C.M.G. in 1874, returned to the colony the same year, and was elected for Warrnambool. In 1875 he formed his fourth and last ministry, which kept power till May 1877, when his party was defeated at the general election. During his eighteen months of office he had to encounter a persistent opposition from Mr Berry and his followers, who systematically obstructed the business of the Assembly, on the ground that the Acting Governor, Sir William Stawell, had improperly refused a dissolution. Sir James M'Culloch, to counteract this obstruction, invented the closure, which was afterwards introduced with some modification into the House of Commons. After his defeat in 1877 Sir James retired from public life and returned to England, where he died on 30th January 1893 at Ewell, Surrey. He was twice married—first, in 1841, to Susan, daughter of the Rev. James Renwick, of Muirton, Scotland; secondly, in 1867, to Margaret, daughter of William Inglis, of Walfat, Dumbartonshire. He left the house of Dennistoun Brothers in 1862, and founded a new firm at Melbourne in conjunction with Leishman, Inglis and Co. of London, under the title of M'Culloch, Sellars and Co. He held several important commercial positions, and was President of the Melbourne Chamber of Commerce. (G. C. L.)

Macdonald, George (1824—), Scottish novelist and poet, was born at Huntly, Aberdeenshire, in 1824; his father, a farmer, was one of the Macdonalds of Glencoe, and a direct descendant of one of the families that suffered in the massacre. Macdonald's youth was passed in his native town, under the immediate influence of the Congregational Church, and in an atmosphere strongly impregnated with Calvinism. He took

his degree at Aberdeen University, and migrated thence to London, studying at Highbury College for the Congregational ministry. In 1850 he was appointed pastor of Trinity Congregational Church, Arundel, and, after resigning his cure there, was engaged in ministerial work in Manchester. His health, however, was unequal to the strain, and after a short sojourn in Algiers he settled in London and adopted the profession of literature. In 1856 he published his first book, *Within and Without*, a dramatic poem; following it in 1857 with a volume of *Poems*, and in 1858 by the delightful "faerie romance" *Phantastes*. His first conspicuous success was achieved in 1862 with *David Elginbrod*, the forerunner of a number of popular novels, which include *Alec Forbes of Howglen* (1865), *Annals of a Quiet Neighbourhood* (1866), *Robert Falconer* (1868), *Malcolm* (1875), *The Marquis of Lossie* (1877), and *Donal Grant* (1883). He was for a time editor of *Good Words for the Young*, and lectured successfully in America in 1872-73. He also wrote several stories for the young, and published some striking volumes of sermons. Both as preacher and as lecturer on literary topics (notably on Shakespeare—his study of *Hamlet* being particularly interesting) George Macdonald's great sincerity and moral enthusiasm, amounting at times to something akin to inspiration, exercised great influence upon thoughtful minds. His verse is homely and direct, and marked by religious fervour and simplicity. As a portrayer of Scottish peasant-life in fiction he was the precursor of a large school, which has benefitted by his example and surpassed its original leader in popularity. The religious tone of his novels is relieved by tolerance and a broad spirit of humour, and the simpler emotions of humble life are sympathetically treated. They show considerable insight into character, and several of his stories turn upon the development of the individual nature under the sway of spiritual ascendancy. Their tone throughout is wholesome and elevating. In 1877 George Macdonald was given a Civil List pension.

Macdonald, Sir John Alexander (1815-1891), first Premier of the Dominion of Canada, and the most conspicuous figure that Canadian politics produced in the 19th century, was born in Glasgow on the 11th of January 1815. His father was Hugh Macdonald, a native of Sutherlandshire; his mother's maiden name was Helen Shaw; among the five children of their family the future statesman was the third. The family emigrated to Canada in 1820, settling first at Kingston, Ontario, and later, on the failure of various undertakings, removing in succession to two of the small neighbouring towns. The father, an unpractical man in matters of business, died in 1841. The energy and capacity displayed by the mother in holding the family together seem to have made a deep impression on her brilliant son. Five years spent at the Kingston Grammar School constituted the lad's only formal education. At the age of fifteen he entered the law office of Mr George Mackenzie of Kingston; he studied there for six years, was called to the bar in 1836, and began in the same town the practice of his profession. This was a particularly critical period in the history of Canada, and one calculated to stimulate political thought in a young and active mind. It was the year before the rebellion of 1837: the condition of the whole country was very unsettled, and it seemed well-nigh impossible to reconcile the differences arising from racial and political antagonisms. During the rebellion young Macdonald volunteered for active service, but the uprising was easily crushed, and his military career never went farther than drilling and marching. The year 1844 saw his entry into political life. In his first address to the electors of Kingston a sentence occurs which strikes

the dominant note of his subsequent political faith and public career:—"I therefore need scarcely state my firm belief that the prosperity of Canada depends upon its permanent connexion with the mother country, and that I shall resist to the utmost any attempt (from whatever quarter it may come) which may tend to weaken that union." For forty-six years of public life this idea gave the main direction to his policy. He was elected by a large majority, and took his seat on 28th November 1844 as a supporter of the Draper Government. In 1847 he was made Receiver-General, with a seat in the Executive Council. The Government of which he thus became a member held office for only ten months, and then, on appealing to the country, was placed in a hopeless minority. The Rebellion Losses Bill, passed by the victorious Liberals and assented to by Lord Elgin in circumstances that provoked a riot ending in the burning of the Houses of Parliament, caused much indignation among the hitherto ultra-loyal Conservative party, and many of its members at this period signed a document favouring annexation to the United States. Macdonald, on the other hand, took steps to form a British American League, having for its object the confederation of all the provinces, the strengthening of the connexion with the mother country, and the adoption of a national commercial policy. He remained in Opposition till 1854, and then, as a consequence of the fierce dissensions connected with the secularization of the clergy reserves in Ontario and the abolition of seigniorial tenure in Quebec, he planned a coalition of the Conservatives and the moderate Reformers, among whom was a large French Canadian element. Out of this union grew the Liberal-Conservative party, of which until his death Macdonald continued to be the most prominent figure. He was Attorney-General for Upper Canada from 1854 to 1857, and then, on the retirement of Colonel Taché, he was himself called on to form a ministry. So closely were parties divided at this time that defeat and reinstatement of Governments followed each other in rapid succession.

The experiment of applying responsible government on party lines to the two Canadian provinces at last seemed to have come to a deadlock. Two general elections and the defeat of four ministries within three years had done nothing to solve the difficulties of the situation. At this critical period a proposal was made for a coalition of parties in order to carry out a broad scheme of British American confederation. The immediate proposal is said to have come from George Brown; the large political idea had long been advocated by Macdonald and Alexander Galt in Upper Canada—by Joseph Howe and others in the Maritime Provinces. The close of the American Civil War, the Fenian raids across the American border, and the dangers incident to the international situation, gave a decisive impulse to the movement. Macdonald, at the head of a representative delegation from Ontario and Quebec, met the public men of the Maritime Provinces in conference at Charlottetown in 1864, and the outline of confederation then agreed upon was filled out in detail at a conference held at Quebec soon afterwards. The constitution then framed was submitted to the Imperial Parliament in the autumn of 1866, and passed early in the following year. On 1st July 1867 the Act by which Canada was confederated as a Dominion under the Crown was proclaimed. In all the discussions leading up to this great step in colonial development Macdonald took the leading part, and thus he naturally became the first Premier of the Dominion. He was made at this time K.C.B. in recognition of his services to the empire.

The difficulties of organizing the new Dominion, the questions arising from diverse claims and the varied con-

ditions of the country, called for infinite tact and resource on the part of the Premier. Federal rights were to be safeguarded against the provincial governments, always jealous of their privileges. The people of Nova Scotia in particular, dissatisfied with the way in which their province had been drawn into the Union, maintained a fierce opposition to the Ottawa Government, until their leader, Joseph Howe, fearing an armed rising, came to an agreement with Macdonald and accepted a seat in his cabinet. The establishment of a supreme court also occupied the attention of Sir John, who had a strong sense of the necessity of maintaining the purity and dignity of the judicial office. The pledge made at confederation with regard to the building of the Intercolonial railway was fulfilled. The North-West

Territories were secured as a part of confederated Canada by the purchase of the rights of the Hudson Bay Company, and the establishment of Manitoba as a province in 1870. Canada's interests were protected during the negotiations which ended in the Treaty of Washington in 1871, and in which Sir John took part as one of the British delegates. In this year British Columbia entered the confederation, one of the provisions of union being that a transcontinental railroad should be built within ten years. This was declared by the Opposition to be impossible. It was possible only to a leader of indomitable will. Charges of bribery against the Government in connexion with the contract for the building of this line led to the resignation of the cabinet in 1874, and for four years Sir John was in Opposition. But he was by no means inactive. During the summer of 1876 he travelled through Ontario

addressing the people on the subject of a commercial system looking to the protection of native industries. This was the celebrated "National Policy" which had been in his thoughts as long ago as the formation of the British American League in 1850. The Government of Mr Alexander Mackenzie refused to consider a protection policy, and determined to adhere to Free Trade with a tariff for revenue only. On these strongly-defined issues the two parties appealed to the people in 1878. The Liberal party was almost swept away, and Sir John, on his return to power, put his policy into effect with a thoroughness that commanded the admiration even of his opponents. He also undertook the immediate construction of the Canadian Pacific railway, which had been postponed by the former Government. The line was begun late in 1880, and finished in November 1885—an achievement which Sir John ranked among his greatest triumphs. "The faith of Sir John," says one of his biographers, "did more to build the road than the money of Mount-Stephen."

During the remaining years of his life his efforts at administration were directed mainly towards the organization and development of the great North-West. From

1878 until his death in 1891 Sir John retained his position as Premier of Canada. For forty-six years of stormy political life he remained true to the cardinal policy that he had announced to the electors of Kingston in 1844. "A British subject I was born; a British subject I will die," says his last political manifesto to the people of the Dominion. At his advanced age the anxiety and excitement of the contested election of 1891 proved too great. An illness followed from which he never recovered. On the 29th of May he suffered a stroke of paralysis, which caused his death eight days later (6th June).

An intelligent view of the career of Sir John Macdonald is only possible when considered in connexion with the political history of Canada and the conditions of its

SIR JOHN A. MACDONALD.

(From a photograph by Wm. Notman and Son, Montreal.)

government during the latter half of the 19th century. Trained in a school where the principles of responsible government were still in an embryonic state, where the adroit management of coalitions and cabals was essential to the life of a political party, and where plots and counterplots were looked upon as a regular part of the political game, he acquired a dexterity and skill in managing men that finally gave him an almost autocratic power among his political followers. But great personal qualities supplemented his political dexterity and sagacity. A strong will enabled him to overcome the passionate temper which marked his youth and, later in his career, a habit of intemperance, which he at first shared with many public men of his time. He was a man of strong ambitions, but these were curbed by a shrewd foresight which led him for a long time to submit to the nominal leadership of other and

smaller men. Politics he made his business, and to this he devoted all his energies. He had the gift of living for the work in hand, without feeling the distraction of other interests. He had a singular faculty for reading the minds and the motives of men, and to this insight he perhaps owed the power of adaptability (called by his opponents shiftiness) which characterized his whole career. To this power the successful guidance of the Dominion through its critical formative period must be ascribed. Few political leaders have ever had such a number of antagonistic elements to reconcile as presented themselves in the first Canadian Parliament after confederation. The man who could manage to rule a congeries of jealous factions, including Irish Catholics and Orangemen, French and English anti-federationists and agitators for independence, Conservatives and Reformers, careful economists and prodigal expansionists, was manifestly a man of unusual power, superior to small prejudices and without strong bias towards any creed or section. Such a man Sir John proved himself to be. His personality stands out at this period as the central power in which each faction chiefly reposed trust, and under which it could join hands with the others in the

service of the State. His singleness of purpose, personal independence, and indomitable energy enabled him to achieve triumphs that to others seemed impossible. After the "Pacific Scandal" of 1874, the leader of the opposite party declared that "John A." (as he was generally called) "has fallen, never to rise again." Yet he not only cleared his own character from the charges laid against him, but succeeded four years later in achieving his most signal party triumph. His natural urbanity allowed him to rule without seeming to rule. When baffled in minor objects he gave way with a good-natured flexibility which brought upon him at times charges of inconsistency. Yet Canada has seen statesmen of more contracted view insist on such small points, fall, and drag down their party with them. He lived at a time when the exigencies of state seemed to require the peculiar talents which he possessed. Entering politics at the dreariest and least profitable stage in Canadian history, he took the foremost part in the movement which made of Canada a nation; he guided that nation through the nebulous stages of its existence, and left it united, strong and vigorous, a monument to his patriotic and far-sighted statesmanship. In the crypt of St Paul's Cathedral a memorial has rightly been placed to him as a statesman, not merely of Canada, but of the Empire. In unveiling that memorial, Lord Rosebery fitly epitomized the meaning of his life and work when he said: "We recognize only this, that Sir John Macdonald had grasped the central idea that the British Empire is the greatest secular agency for good now known to mankind; that that was the secret of his success; and that he determined to die under it, and strove that Canada should live under it."

The authorized and most trustworthy biography of Sir John A. Macdonald is one written by his private secretary, Joseph Pope (2 vols., Arnold). Others have been written by his nephew, Colonel J. Pennington Macpherson, and by Mr J. E. Collins. A bright and amusing anecdotal life has also been compiled by Mr E. D. Biggar (Montreal, J. Lovell and Sons). (G. R. P.)

McDowell, Irvin (1818–1885), American soldier, was born in Columbus, Ohio, on 15th October 1818, and after early training in France graduated at the United States Military Academy in 1838. He was adjutant and instructor at West Point, 1841–45, won brevet rank in the Mexican war, and served as adjutant-general, chiefly at Washington, until 1861, being promoted to major in 1856. While inspector on General Scott's staff and occupied in mustering volunteers at the capital, he was made brigadier-general in May 1861, and placed in command during the premature Virginian campaign of July, which ended in the defeat at Bull Run. Under McClellan he became a corps commander and major-general of volunteers (March 1862). When the Peninsular campaign began, McDowell's column was detained against McClellan's wishes, and, eventually united with General John Pope, engaged at Cedar Mountain, Rappahannock Station, and the second Bull Run. McDowell was relieved of duty in the field (September 1862), sharing Pope's odium, and served at the Pacific coast 1864–68. He became (November 1872) major-general of regulars, was retired in 1882, and died at San Francisco, California, on 4th May 1885. His military merits during the Civil War have provoked much discussion. He appears to have been a faithful, unselfish, energetic soldier, in patriotic sympathy with the Administration, and capable of the highest achievement as commander when well sustained. But he was perhaps too ready to brave great risks at the instance of his superiors, and hence lost instead of gained by his early opportunities. (J. SCH.)

Macduff, a police burgh, burgh of barony, seaport, watering-place, and railway station, 1½ miles east of Banff, Scotland. It is an important centre for the herring fishing, and has a good bathing beach and a mineral well; also a town hall. The harbour, constructed by the duke of Fife, was transferred to the burgh in 1898. Population (1881), 3650; (1901), 3418.

M A C E D O N I A.

THE name Macedonia is now generally given to that portion of European Turkey which is bounded on the N. by the Kara-Dagh mountain range and the frontier of Bulgaria, on the E. by the river Mesta, on the S. by the Ægean Sea and the frontier of Greece, and on the W. by an ill-defined line coinciding with the chains of Shar, Grammos, and Pindus. The limits thus marked out do not correspond with those of any Turkish administrative division or with any ethnical boundary. In Macedonia are included the vilayets of Selanik (Salonica), the eastern and greater portion of the vilayet of Monastir (sanjaks of Monastir, Servia, and part of that of Kortcha), and the south-eastern portion of the vilayet of Kossovo (sanjak of Usküb). The coast-line is broken by the remarkable peninsula of Chalcidice, with its three promontories of Athos (anc. *Acte*), Longos (*Sithonia*), and Cassandra (*Pallene*). The country is divided into two almost equal portions by the river Vardar (anc. *Axios*), the valley of which has always constituted the principal route from Central Europe to the Ægean. The other important rivers are the Struma (*Strymon*) and Mesta (*Nestos*), to the east, running almost parallel to the Vardar, and the Bistritza (anc. *Haliacmon*) to the south, all falling into the Ægean. The Struma runs through a narrow defile till within a short distance of the sea; the valleys of the other rivers and their tributaries broaden here and there into fertile upland basins, which were formerly lakes. Of these the extensive plateau of Monastir (*Vitolia*), drained

by the Tchernia, is the most remarkable. The principal lakes are Ochrida, on the confines of Albania; Prespa, separated from Ochrida by the Galinitza mountains; Ostrovo, midway between Prespa and the Vardar; Tachino, on the lower course of the Struma; and Beshik (*Bolbe*), separating the Chalcidian peninsula from the mainland. The surface of the country is generally mountainous. The great chain of Rhodope, continued to the north by the Rilaska and Osogovska Planina, forms a natural boundary on the north; the principal summit, Musallá (2924 metres), is just over the Bulgarian frontier. Between the upper courses of the Mesta and Struma is the Perim Dagh, or Pirin Planina (anc. *Orbelos*), with Elin (2681 metres), continued to the south by the Bozo Dagh; between the Struma and the Vardar are the Belasitza, Krusha, and other ranges; west of the Vardar the lofty Shar chain, terminating at its eastern extremity in Liubotrn, supposed to be the highest mountain in the peninsula (3050 metres), continues the natural boundary, which is prolonged towards the south by the Grammos and Pindus ranges. Between the Vardar and the plain of Monastir the Nija range culminates in Kaimakzolan (2317 metres); south-west of Monastir is Mount Peristeri (2350 metres), overlooking Lake Prespa; between Lake Ostrovo and the lower Bistritza are the Bermios and Kitarion ranges, with Doxa (1600 metres) and Turla (about 1000 metres). South of the Bistritza are the Cambunian mountains, forming the boundary of Thessaly, and terminating to the east in the

imposing mass of Elymbos, or Olympus (2985 metres). Lastly, Mount Athos, at the extremity of the peninsula of that name, reaches the height of 1935 metres. The general aspect of the country is bare and desolate, especially in the neighbourhood of the principal routes; the trees have been destroyed, and large tracts of land remain uncultivated. Magnificent forests, however, still clothe the slopes of Rhodope and Pindus. The well-wooded and cultivated districts of Grevena and Kastoria, which are mainly inhabited by a Vlach population, are remarkably beautiful, and the scenery around Lakes Ochrida and Prespa is exceedingly picturesque. The climate is severe; the spring is often rainy, and the melted snows from the encircling mountains produce inundations in the plains. The natural products are in general similar to those of southern Bulgaria and Servia—the fig, olive, and orange, however, appear on the shores of the Ægean, and in the sheltered valleys of the southern region. The best tobacco in Europe is grown on the southern declivity of Rhodope in the Kavala district.

The population of Macedonia may perhaps be estimated at 2,200,000. Of this number about 1,300,000 are Christians, belonging to various churches and nationalities; more than 800,000 are Mahomedans, and about 75,000 are Jews. Of the Christians, the great majority profess the Eastern Orthodox faith, owing allegiance either to the Greek patriarchate or the Bulgarian exarchate. Among the Orthodox Christians are reckoned some 4000 Turks. The small Catholic minority is composed chiefly of "Uniate" Bulgarians (about 3600), occupying the districts of Kukush and Doiran; there are also some 2000 Bulgarian Protestants, principally inhabiting the valley of Razlog. The Mahomedan population is mainly composed of Turks (about 500,000). In addition to these there are some 130,000 Bulgars, 120,000 Albanians, 35,000 gypsies, and 14,000 Greeks, together with a smaller number of Vlachs, Jews, and Circassians, who profess the creed of Islam. The Turkish statistics, which are entirely untrustworthy, take religion, not nationality, as the basis of classification. All Moslems, to whatever race they may belong, are included in the *millet*, or nation, of Islam. The Rûm, or Roman (*i.e.*, Greek) *millet* comprises all those who acknowledge the authority of the Œcumenical Patriarch, and consequently includes, in addition to the Greeks, the Servians, the Vlachs, and a certain number of Bulgarians; the Bulgar *millet* comprises the Bulgarians who accept the rule of the exarchate; the other *millets* are the Katolik (Catholics), Ermeni (Gregorian Armenians), Musevi (Jews), and Prodesdan (Protestants). The population of Macedonia, at all times scanty, has undoubtedly diminished in recent years. The prevailing insecurity, the exactions of the Turkish officials, the severities practised by the authorities in the repression of political agitation, the prevalence of brigandage, authorized and unauthorized, and the ravages of Albanian marauders in the western districts, have all tended to this result. For many years there has been a continual outflow of the Christian population in the direction of Bulgaria, Servia, and Greece, and a corresponding emigration of the Turkish peasantry to Asia Minor. Many of the smaller villages are being abandoned by their inhabitants, who migrate for safety to the more considerable towns—the latter are usually situated at some point where a mountain pass descends to the outskirts of the plains. In the agricultural districts the Christian peasants, or *rayas*, are either small proprietors or cultivate holdings on the estates of Turkish landowners, receiving a certain portion of the product, after the payment of the tithe and other taxes to the Government. The upland districts are thinly inhabited by a nomad pastoral population.

Inhabited by a variety of races, Macedonia possesses a peculiar importance as the principal theatre of the struggle of nationalities in Eastern Europe. All the races which dispute the reversion of the Turkish possessions in Europe are represented within its borders. Here are centred the rival aspirations of the various states which during the 19th century became detached from the Ottoman empire. The Macedonian problem may therefore be described as the quintessence of the Eastern Question. The Turks, the ruling race, form less than a quarter of the entire population, and their numbers are steadily declining. The first Turkish immigration from Asia Minor took place under the Byzantine emperors before the conquest of the country. The first purely Turkish town, Yenijé-Vardar, was founded on the ruins of Vardar in 1362. After the capture of Salonica (1430), a strong Turkish population was settled in the city, and similar colonies were founded in Monastir, Ochrida, Serres, Drama, and other important places. In many of these towns half or more of the population is still Turkish. A series of military colonies was subsequently established at various points of strategic importance along the principal lines of communication. Before 1360 large numbers of nomad shepherds, or Yuruks, from the district of Konieh, in Asia Minor, had settled in the country; their descendants are still known as Konariotes. Further immigration from this region took place from time to time up to the middle of the 18th century. After the establishment of the feudal system in 1397, many of the Seljuk noble families came over from Asia Minor; their descendants may be recognized among the beys or Moslem landowners in southern Macedonia. At the beginning of the 18th century the Turkish population was very considerable, but since that time it has continuously decreased. A low birth-rate, the exhaustion of the male population by military service, and great mortality from epidemics, against which Moslem fatalism takes no precautions, have brought about a decline which has latterly been hastened by emigration. On the other hand, there has been a considerable Moslem immigration from Bosnia, Servia, Bulgaria, and Greece, but the newcomers, or *mohajirs*, do not form a permanent colonizing element, and most of them remain housed in miserable dwellings on the outskirts of the larger towns. The Turkish rural population is found in three principal groups: the most easterly extends from the Mesta to Drama, Pravishta, and Orfano, reaching the sea-coast on either side of Kavala, which is partly Turkish, partly Greek. The second, or central, group begins on the sea-coast, a little west of the mouth of the Strymon, where a Greek population intervenes, and extends to the north-west along the Kara-Dagh and Belasitza ranges in the direction of Strumnitza, Veles, Shtip, and Radovisht. This long line of Turkish colonies was probably designed to protect the Vardar valley, and to separate the Christian population into two divisions. The third, or southern, group is centred around Kaïlar, an entirely Turkish town, and extends from Lake Ostrovo to Selfijé (Servia). The second and third groups are mainly composed of Konariot shepherds. Besides these fairly compact settlements there are numerous isolated Turkish colonies in various parts of the country. The Christian Turks already alluded to are resident at Zeliachovo, in the Bozo Dag; they are probably descendants of the earliest colonists introduced by the Byzantine emperors. The Turkish rural population is quiet, sober, and orderly, presenting some of the best characteristics of the race. The urban population, on the other hand, has become much demoralized, while the official classes, from the gendarmes to the highest functionaries, are as a rule corrupt and avaricious, and seem to have parted with all scruple in their dealings with the

Races: the
Turks.

Christian peasantry. The Turks, though still numerically and politically strong, fall behind the other nationalities in point of intellectual culture, and the contrast is daily becoming more marked owing to the educational activity of the Christians. Originally a nomad race, they have never become rooted in the soil, and remigration to Asia Minor will probably be their ultimate destiny.

The Greek and Vlach populations are not always easily distinguished, as a considerable proportion of the latter has been Hellenized. Both show a remarkable

The Greeks and Vlachs.

aptitude for commerce; the Greeks have maintained their language and religion, and the Vlachs their religion, with greater tenacity than any of the other races. From the date of the Ottoman conquest until comparatively recent times, the Greeks occupied an exceptional position in Macedonia, as elsewhere in the Turkish empire, owing to the privileges conferred on the patriarchate of Constantinople, and the influence subsequently acquired by the great Phanariot families. All the Christian population belonged to the Greek *millet* and called itself Greek; the bishops and higher clergy were exclusively Greek; Greek was the language of the upper classes, of commerce, literature, and religion, and Greek alone was taught in the schools. The supremacy of the patriarchate was consummated by the suppression of the autocephalous Slavonic churches of Ipek in 1766, and Ochrida in 1767. In the latter half of the 18th century Greek ascendancy in Macedonia was at its zenith; its decline began with the War of Independence, the establishment of the Hellenic kingdom, and the extinction of the Phanariot power in Constantinople. The patriarchate, nevertheless, maintained its exclusive jurisdiction over all the Orthodox population till 1870, when the Bulgarian exarchate was established, and the Greek clergy continued to labour with undiminished zeal for the spread of Hellenism. Notwithstanding their venality and intolerance, their merits as the only diffusers of culture and enlightenment in the past should not be overlooked. The process of Hellenization made greater progress in the towns than in the rural districts of the interior, where the non-Hellenic populations preserved their languages, which alone saved the several nationalities from extinction. The typical Greek, with his superior education, his love of politics and commerce, and his distaste for laborious occupations, has always been a dweller in cities. In Salonica, Serres, Kavala, Kastoria, and other towns in southern Macedonia the Hellenic element is strong; in the northern towns it is insignificant, except at Melnik, which is almost exclusively Greek. The Greek rural population extends from the Thessalian frontier to Kastoria and Verria (*Beroza*); it occupies the whole Chalcidian peninsula and both banks of the lower Strymon from Serres to the sea, and from Nigrita on the west to Pravishta on the east; there are also numerous Greek villages in the Kavala district. The Mahommedan Greeks, known as *Valachites*, occupy a considerable tract in the upper Bistritza valley near Grevena and Liapsista. The purely Greek population of Macedonia may possibly be estimated at a quarter of a million. The Vlachs, or Rumans, who call themselves *Aromuni* or *Aromani* (i.e., Romans), are also known as *Kutzovlachs* and *Tzintzars*: the latter two appellations are, in fact, nicknames, "Kutzovlach" meaning "lame Vlach," while "Tzintzar" denotes their inability to pronounce the Rumanian *cinci* (five). The Vlachs are styled by some writers "Macedo-Rumans," in contradistinction to the "Daco-Rumans," who inhabit the country north of the Danube. They are, in all probability, the descendants of the Thracian branch of the aboriginal Thracio-Illyrian population of the Balkan peninsula, the Illyrians being represented by the Albanians. This early native population,

which was apparently Hellenized to some extent under the Macedonian empire, seems to have been Latinized in the period succeeding the Roman conquest, and probably received a considerable infusion of Italian blood. However this may be, the Latin origin of the Vlach language is indisputable. There is evidence to show that Latin was generally spoken by the peasantry of the interior before the Slavonic invasion. The Latin-speaking race was expelled from the plains by the Slavonic immigrants, and took refuge in the mountainous districts, where it still remains. The Vlachs are for the most part either highland shepherds or wandering owners of horses and mules. Their settlements are scattered all over the mountains of Macedonia: some of these consist of permanent dwellings, others of huts occupied only in the summer. The compactest groups are found in the Pindus and Agrapha mountains (extending into Albania and Thessaly), in the neighbourhood of Monastir, Grevena, and Kastoria, and in the district of Meglen. The Vlachs who settle in the lowland districts are excellent husbandmen. The urban population is considerable; the Vlachs of Salonica, Monastir, Serres, and other large towns are, for the most part, descended from refugees from Moschopolis, once the principal centre of Macedonian commerce. At the beginning of the 18th century this Vlach city numbered 80,000 inhabitants; it was plundered by the Albanians in 1769, and ultimately destroyed by Ali Pasha in 1788. The towns of Metzovo, on the confines of Albania, and Klisura, in the Bistritza valley, are almost exclusively Vlach. The urban and most of the rural Vlachs are bilingual, speaking Greek as well as Rumanian; a great number of the former have been completely Hellenized, partly in consequence of mixed marriages, and many of the wealthiest commercial families of Vlach origin are now devoted to the Greek cause. The Vlachs of Macedonia possibly number 90,000, of whom only some 3000 are Mahommedans. The Macedonian dialect of the Rumanian language differs mainly from that spoken north of the Danube in its vocabulary and certain phonetic peculiarities; it contains a number of Greek words which are often replaced in the northern speech by Slavonic or Latin synonyms.

The Albanians, called by the Turks and Slavs *Arnauts*, by the Greeks *Ἀρβανίται*, and by themselves *Shkyipetar*, have always been the scourge of western Macedonia; even before the Turkish conquest these predatory mountaineers were accustomed to devastate the fertile valleys inhabited by the agricultural Slavonic population. After the first Turkish invasion of Albania many of the chiefs or beys adopted Mahommedanism, but the conversion of the great bulk of the people took place in the 16th and 17th centuries. This change of faith was productive of serious consequences to their Christian neighbours. Professing the creed of the dominant Power and entitled to bear arms, the Albanians were enabled to push forward their limits at the expense of the defenceless population around them, and their encroachments have continued to the present day. They have not only advanced themselves, but have driven to the eastward numbers of their Christian compatriots and a great portion of the once-prosperous Vlach population of Albania. The indulgence extended to them by the Porte has been requited by constant rebellions: with the decline of the Ottoman power in the 18th century the arrogance of the Albanian chieftains increased, and their military energies were as often employed in combating the Turkish authority as in prosecuting local feuds or raiding the Christian peasantry. The ravages of Ali Pasha of Tepelen, who maintained a practically independent sovereignty at Iannina from 1788 to 1832, will long be remembered in Macedonia: in his time the

The Albanians, Circassians, &c.

Albanians established themselves in the district of Kortcha and on the southern shores of Lake Ochrida, ejecting the Slavonic population. In 1830 Arslan Bey and other Albanian chiefs, who had revolted and invaded Macedonia, were invited to Monastir under pretext of an armistice by the Grand Vizier, Reshid Pasha, and were massacred with 500 of their followers as they were about to partake of a banquet prepared by their host. A little later an Albanian invasion under Mustafa Pasha of Scutari was repulsed by the Grand Vizier, and the Slavonic population was re-established in the district of Ochrida. In recent years Albanian revolts and disturbances have been frequent along the western confines of Macedonia, especially in the neighbourhood of Dibra: the Slavonic peasants have been the principal sufferers from these troubles, while the Porte, in pursuance of the "Islamic policy" adopted by the Sultan Abdul Hamid II., deals tenderly with the recalcitrant believers. An invincible repugnance to the payment of taxation, and an equally strong aversion from regular military service are the main causes of Albanian discontent and the principal obstacles to a farther advance of the race into Macedonia. While confined to their mountains the tribesmen escape both these obligations, and enjoy greater facilities for plundering the populations of the plains. In southern Macedonia the Albanians of the Tosk race extend over the upper Bistritza valley as far west as Kastoria, and reach the southern and western shores of Lakes Prespa and Ochrida: they are also numerous in the neighbourhood of Monastir. In northern Macedonia the Albanians are of the Gheg stock: they have advanced in large numbers over the districts of Dibra, Kalkandele, and Usküb, driving the Slavonic population before them. The total number of Albanians in Macedonia may be estimated at about 120,000, of whom some 10,000 are Christians (chiefly Orthodox Tosks). Without a national literature, a common religion, or any of the elements of unity, the Albanians, notwithstanding their remarkable self-assertiveness, cannot be regarded as an important political factor in Macedonia. (For the origin, language, and institutions of this singular race, see ALBANIA, vol. xxv.) The Circassians, who occupy some villages in the neighbourhood of Serres, now scarcely number 3000: their predatory instincts may be compared with those of the Albanians. The Jews had colonies in Macedonia in the time of St Paul, but no trace remains of these early settlements. The Jews now found in the country descend from refugees who fled from Spain during the persecutions at the end of the 15th century: they speak a dialect of Spanish, which they write with Hebrew characters. They form a flourishing community at Salonica, which numbers more than half the population: their colonies at Monastir, Serres, and other towns are poor. A small proportion of the Jews, known as *Deunmé* by the Turks, have embraced Mahomedanism.

With the exception of the southern and western districts already specified, the principal towns, and certain isolated tracts, the whole of Macedonia is inhabited by a race or races speaking a Slavonic dialect. If language is adopted as a test, the great bulk of the rural population must be described as Slavonic. The Slavs first crossed the Danube at the beginning of the 3rd century of our era, but their great immigration took place in the 6th and 7th centuries. They overran the entire peninsula, driving the Greeks to the shores of the Ægean, the Albanians into the Mirdite country, and the Latinized population of Macedonia into the highland districts, such as Pindus, Agrapha, and Olympus. Slavonic place-names, occurring in regions where every other trace of the immigration has now dis-

appeared, bear witness to the multitude of the invaders and the permanency of their settlements. The Slavs, a primitive agricultural and pastoral people, were often unsuccessful in their attacks on the fortified towns, which remained centres of Hellenism. In the outlying parts of the peninsula they were absorbed, or eventually driven back, by the original populations, but in the central region they probably assimilated a considerable proportion of the Latinized races. The western portions of the peninsula were occupied by Serb and Slovene tribes: the Slavs of the eastern and central portions were conquered at the end of the 7th century by the Bulgarians, a Ugro-Finnish horde, who established a despotic political organization, but being less numerous than the subjected race, were eventually absorbed by it. The Mongolian physical type, which prevails in the districts between the Balkans and the Danube, is also found in central Macedonia, and may be recognized as far west as Ochrida and Dibra. In general, however, the Macedonian Slavs differ somewhat both in appearance and character from their neighbours beyond the Bulgarian and Servian frontiers: the peculiar type which they present is probably due to a considerable admixture of Vlach, Hellenic, Albanian, and Turkish blood, and to the influence of the surrounding races. Asiatic colonization under the Byzantine emperors from the 9th to the 13th century has perhaps in some degree affected the Slavs as well as the other races in the southern half of Macedonia. Almost all independent authorities, however, agree that the bulk of the Slavonic population of Macedonia is Bulgarian. The principal indication is furnished by the language, which, though resembling Servian in some respects (*e.g.*, the case-endings, which are occasionally retained), presents most of the characteristic features of Bulgarian (see BULGARIA, Part III. vol. xxvi.). Among these may be mentioned the suffix-article, the nasal vowels (retained in the neighbourhood of Salonica and Kastoria, but modified elsewhere as in Bulgarian), the retention of *l* (*e.g.*, *vulk* "wolf," *bel* "white"; Servian *vuk*, *beo*), and the loss of the infinitive. There are at least four Slavonic dialects in Macedonia, but the suffix-article, though varying in form, is a constant feature in all. The Slavs of western Macedonia are of a lively, enterprising character, and share the commercial aptitude of the Vlachs: those of the eastern and southern regions are a quiet, sober, hard-working agricultural race, more obviously homogeneous with the population of Bulgaria. In upper Macedonia large family communities, resembling the Servian and Bulgarian *zadruga*, are commonly found: they sometimes number over 50 members. The whole Slavonic population of Macedonia may be estimated at about 1,150,000, of whom about 1,000,000 are Christians of the Orthodox faith. The majority of the latter now own allegiance to the Bulgarian exarchate, but a certain minority still remains faithful to the Greek patriarchate. The Moslem Bulgarians form a considerable element: they are found principally in the valley of the upper Mesta and the Rhodope district, where they are known as *Pomaks* or "helpers," *i.e.*, auxiliaries to the Turkish army. Other groups exist in the neighbourhood of Usküb and Dibra. The conversion of the Pomaks took place at various intervals from the 15th to the 18th century: for a long period these mountaineers, a remarkably fine race, maintained a position of absolute independence under their beys and agas. One of their principal villages, Dospat, was destroyed by raiders from over the Bulgarian frontier in 1895.

The embittered struggle of the rival nationalities in Macedonia dates from the middle of the 19th century. Until that period the Greeks, owing to their superior culture and their privileged position, exercised an exclusive influence over the whole population professing the Orthodox

faith. All Macedonia was either Moslem or Orthodox Christian, without distinction of nationalities, the Catholic or Protestant *millets* being inconsiderable. The first opposition to Greek ecclesiastical ascendancy came from the Bulgarians. The Bulgarian literary revival, which took place in the earlier part of the 19th century, was the precursor of the ecclesiastical and national movement which resulted in the establishment of the exarchate in 1870 (see BULGARIA, Parts II. and III.). In the course of the struggle some of the Bulgarian leaders entered into negotiations with Rome; a Bulgarian uniate church was recognized by the Porte, and the pope nominated a bishop, who, however, was mysteriously deported to Russia a few days after his consecration (1861). The first exarch, who was elected in 1871, was excommunicated with all his followers by the patriarch, and a considerable number of Bulgarians in Macedonia—the so-called “Bulgarophones”—fearing the reproach of schism, or influenced by other considerations, refrained from acknowledging the new spiritual power. Many of the recently converted uniates, on the other hand, offered their allegiance to the exarch. The firman of the 28th February 1870 specified a number of districts within the present boundaries of Bulgaria and Servia, as well as in Macedonia, to which Bulgarian bishops might be appointed; other districts might be subjected to the exarchate should two-thirds of the inhabitants so desire. In virtue of the latter provision the districts of Veles, Ochrida, and Usküb declared for the exarchate, but the Turkish Government refrained from sanctioning the nomination of Bulgarian bishops to these dioceses. It was not till 1891 that the Porte, at the instance of Stamboloff, the Bulgarian prime minister, whose demands were supported by the Triple Alliance and Great Britain, issued the *berat*, or exequatur, for Bulgarian bishops at Ochrida and Usküb; the sees of Veles and Nevrokop received Bulgarian prelates in 1894, and those of Monastir, Strumnitza, and Dibra in 1898. The Bulgarian position was further strengthened in the latter year by the establishment of “commercial agents” representing the principality at Salonica, Usküb, Monastir, and Serres. During this period (1891–1898) the Bulgarian propaganda, entirely controlled by the spiritual power and conducted within the bounds of legality, made rapid and surprising progress. In latter years the interference of the Macedonian committee at Sofia, in which the advocates of physical force predominate, has done much to injure the movement; the hostility of the Porte has been provoked and the sympathy of the Powers alienated by a series of assassinations and other crimes. According to the official figures, the Bulgarian schools, which in 1893 were 554, with 30,267 pupils and 853 teachers, were, in 1898, 762 (including 68 secondary schools), with 39,466 pupils and 1778 teachers. The Rumanian movement comes next to the Bulgarian in order of time. The Vlachs had shown greater susceptibility to Greek influence than any of the other non-Hellenic populations of Macedonia, and, though efforts to create a Rumanian propaganda were made as early as 1855, it was not till after the union of the principalities of Wallachia and Moldavia in 1861 that any indications of a national sentiment appeared amongst them. In 1886 the principal apostle of the Rumanian cause, a priest named Margaritis, founded a gymnasium at Monastir, and the movement, countenanced by the Porte, supported by the French Catholic missions, and to some extent encouraged by Austria, has made no inconsiderable progress since that time. There are now about forty Rumanian schools in Macedonia, including two gymnasia, and large sums are devoted to their maintenance by the ministry of education at Bucharest, which

also provides qualified teachers. The Rumanian and Servian movements are at a disadvantage compared with the Bulgarian, owing to their want of an ecclesiastical organization, the orthodox Vlachs and Serbs in Turkey owning allegiance to the Greek patriarchate. The Governments of Bucharest and Belgrade have therefore endeavoured to obtain the recognition of Vlach and Servian *millets*, the former demanding the establishment of a Rumanian bishopric at Monastir, while the latter seeks the restoration of the patriarchate of Ipek and the appointment of a Servian metropolitan at Usküb. Their efforts, however, have hitherto been unsuccessful. The Servian movement in Macedonia is of comparatively recent date. Previously to 1878 the hopes of the Servians were centred on Bosnia, Herzegovina, and the vilayet of Kossovo; but when the Berlin Treaty assigned Bosnia and Herzegovina to Austria, the national aspirations were directed to Macedonia, the Slavonic population of which was declared to be Servian. The strained relations existing between Russia and Bulgaria from 1886 to 1895 were to the advantage of the Servian propaganda, which since 1890 has made remarkable progress. Great expenditure has been incurred by the Servian Government in the opening and maintenance of schools. At the beginning of 1899 there were stated to be 178 Servian schools in the vilayets of Usküb, Salonica, and Monastir (including fifteen gymnasia), with 321 teachers and 7200 pupils. The Albanian movement has not yet taken definite shape, and its future development seems doubtful. Some of the Albanian chiefs have demanded the establishment of schools in which their language will be taught, but their request has been persistently refused by the Porte. Notwithstanding the encroachments of their rivals, the impoverishment of the patriarchate, and the injury sustained by their cause in 1897, the Greeks still maintain a large number of schools; according to statistics prepared at Athens there were in 1901, 927 Greek schools in the vilayets of Salonica and Monastir (including five gymnasia), with 1397 teachers and 57,607 pupils. The great educational activity displayed by the proselytizing movements in Macedonia, while tending to the artificial creation of parties, daily widens the contrast between the progressive Christian and the backward Moslem populations, and must sooner or later bring about a change in the present system of government. Meanwhile the reforms stipulated by Article XXIII. of the Berlin Treaty have neither been carried out by the Porte nor insisted upon by the Powers.

Macedonia, like the neighbouring Balkan countries, still awaits exploration; as yet we possess but scanty indications of the earlier developments of civilization in these regions. This is especially true with regard *Antiquities.* to the most primitive epoch, although there can be little doubt that the ancient indigenous population has left traces behind it which will one day be brought to light. The numerous tumuli which occur in the plains, more particularly in the valley of the Vardar, have not yet been systematically investigated; excavations, however, have been made by Körte and Franke at Niausta and near Salonica (see Kretschner, *Einleitung in die Geschichte der griechischen Sprache*, pp. 176, 421), and fragments of primitive pottery, with peculiar characteristics, have been found by M. Perdrizet at Tehepelje, on the left bank of Lake Tachino. The oldest archæological monuments of Macedonia are its coins, for which the mines of Crenides (the later Philippi), at the foot of Mount Pangæus, of Chalcidice, of the island of Thasos, and of the mountains between Lake Prasias and the ancient Macedonian kingdom (Herod. v. 17), furnished abundance of metal. From the reign of Alexander I., the epoch of the Persian wars, the Macedonian dynasty issued silver coins of a purely Greek

style. The Thracian communities around Mount Pangæus also produced a variety of coins, especially at the beginning of the 5th century. The great octodrachms of this period were perhaps struck for the purpose of paying tribute to the Persians when the country between the Strymon and the Nestos was in their possession; most of the specimens have been found in Asia Minor. These large pieces present many characteristics of the Ionian style; it is evident that the Thracians derived the arts of minting and engraving from the neighbouring Thasos, itself a colony from the Ionian Paros. The monarchs of Pella were enthusiastic admirers of Hellenic culture, and their court was doubtless frequented by Greek sculptors as well as men of letters, such as Herodotus and Euripides. At Pella has been found a funerary *stèle* of the late 5th or early 4th century representing a Macedonian *hetærus*—a beautiful specimen of the best Greek art, now preserved in the Imperial Ottoman Museum at Constantinople. To the Hellenic period belong the vaulted tombs under tumuli discovered at Pella, Pydna, Palatitza, and other places; the dead were laid in marble couches ornamented with sculptures, like those of the so-called sarcophagus of Alexander at Constantinople. These tombs doubtless received the remains of the Macedonian nobles and *hetæri*; in one of them a fresco representing a conflict between a horseman and a warrior on foot has been brought to light by Kinch. Similarly-constructed places of sculpture have been found at Eretria and elsewhere in Greece. At Palatitza the ruins of a remarkable structure, perhaps a palace, have been laid bare by Heuzey and Daumet. Unlike Greece, where each independent city had its acropolis, Macedonia offers few remnants of ancient fortification; most of the country towns appear to have been nothing more than open market-centres. The most interesting ruins in the country are those of the Roman and Byzantine epochs. Salonica (Thessalonica) in the time of the Low Empire was one of the greatest cities in the world. Of its two triumphal arches, one, the "Vardar Gate," which marked the end of the Via Egnatia, has been recently demolished; the other, which has been proved by Kinch to commemorate the victories of Galerius, is one of the largest structures of the kind in existence. Between these stood the beautiful monument with caryatides known as *Las Escantadas*, the fragments of which have been conveyed to Paris, and have latterly been put together at the Louvre. For the unique Byzantine churches of Salonica, with their interesting mosaics, the work of Texier and Pullan should be consulted. The celebrated marble *ambon* of the church of St George, with reliefs representing the adoration of the Magi, was removed to Constantinople in 1899. The conversion of these churches into mosques has preserved them from destruction, though not from disfigurement. The walls of Salonica are among the most interesting constructions of Byzantine military architecture; they have been repaired at various epochs, and numerous sarcophagi and fragments of Greek and Roman temples are built up in the masonry. The Byzantine fortifications and aqueduct of Kavala are also remarkable. At Verria (*Bereca*) may be seen some Christian remains, at Melnik a palace of the age of the Comneni, at Serres a Servian fortress built by Dushan. The remains at Filibejik (*Philippi*) are principally of the Roman and Byzantine periods; the numerous *ex voto* rock-tablets of the acropolis are especially interesting. The Roman inscriptions found in Macedonia are mainly funerary, but include several ephêbic lists. The funerary tablets afford convincing proof of the persistence of the Thracian element, notwithstanding Hellenization and Latinization; many of them, for instance, represent the well-known Thracian horseman hunting the wild boar.

MOUNT ATHOS.

The picturesque promontory of Mount Athos (Greek *Ἁγίου Ὄρους*, Turkish *Aineros*, Italian *Monte Santo*) possesses a peculiar interest, owing to its unique group of monastic communities with their mediæval customs and institutions, their treasures of Byzantine art and rich collections of manuscripts. The promontory is about 40 miles in length, with a breadth varying from 4 to 7 miles; its whole area belongs to the various monasteries. It was inhabited in the earliest times by a mixed Greek and Thracian population; of its five cities mentioned by Herodotus few traces remain; some inscriptions discovered on the sites have been published by Leake. The legends of the monks attribute the first religious settlements to the age of Constantine, but the hermitages are first mentioned in historical documents of the 9th century. It is conjectured that the mountain was at an earlier period the abode of anchorites, whose numbers were increased by fugitives from the iconoclastic persecutions (726–842). The "cenobian" rule to which many of the monasteries still adhere was established by St Athanasius, the founder of the great monastery of Laura, in 969. Under a constitution approved by the Emperor Constantine Monomachos in 1046, women and female animals were excluded from the Holy Mountain. In 1060 the community was withdrawn from the authority of the Patriarch of Constantinople, and a monastic republic was practically constituted. Owing to the timely submission of the monks to the Turks after the capture of Salonica (1430), their privileges were respected by successive sultans: a tribute is paid to the Turkish Government, which is represented by a resident *kaimakam*, and the community is allowed to maintain a small police force. Under the present constitution, which dates from 1783, the general affairs of the commonwealth are entrusted to an assembly (*σύναξις*) of twenty members, one from each monastery; a committee of four members, chosen in turn, styled *epistates* (*ἐπιστάται*), forms the executive. The president of the committee (*ὁ πρῶτος*) is also the president of the assembly, which holds its sittings in the village of Karyes. The twenty monasteries, which all belong to the order of St Basil, are: Laura (*ἡ Λαῖρα*), founded in 963; Vatopédi (*Βατοπέδιον*), said to have been founded by the Emperor Theodosius; Rossikón (*Ῥωσσικόν*), the Russian monastery; Chilandári (*Χιλαντάριον*: variously derived from *χίλιοι ἄνδρες* and *χίλια λεοντάρια*), founded by the Servian prince Stephen Nemanya; Iveron (*ἡ μονὴ τῶν Ἰβήρων*), founded by Iberians, or Georgians; Esphigmenú (*τοῦ Ἐσφιγμένου*: the name is derived from the confined situation of the monastery); Kutlumush (*Κουτλουμούση*); Pandocratoros (*τοῦ Παντοκράτορος*); Philotheu (*Φιλοθέου*); Caracallu (*τοῦ Καρακάλλου*); St Paul (*τοῦ ἁγίου Παύλου*); St Denis (*τοῦ ἁγίου Διονυσίου*); St Gregory (*τοῦ ἁγίου Γρηγορίου*); Simópetra (*Σιμόπετρα*); Xeropotámu (*τοῦ Ξεροποτάμου*); St Xenophon (*τοῦ ἁγίου Ξενοφώντος*); Dochiariú (*Δοχειαρίου*); Constamonítu (*Κωνσταμονίτου*); Zográphu (*τοῦ Ζωγράφου*); and Stavronikítu (*τοῦ Σταυρονικίτου*). The "cenobian" monasteries (*κοινόβια*), each under the rule of an abbot (*ἡγούμενος*), are subjected to severe discipline; the brethren are clothed alike, take their meals (usually limited to bread and vegetables) in the refectory, and possess no private property. In the "idiorrhhythmic" monasteries (*ιδιορρυθμικά*), which are governed by two or three annually elected wardens (*ἐπίτροποι*), a less stringent rule prevails, and the monks are allowed to supplement the fare of the monastery from their private incomes. Dependent on the several monasteries are twelve *sketes* (*σκήτια*, *ἀσκητήρια*), or monastic settlements, some of considerable size, in which

a still more ascetic mode of life prevails: there are, further, several *metochs* or farms (*μετόχια*), and many hundred hermitages (*κελλάς*). The monasteries, with the exception of Rossikon (St Panteleimon) and the Serbo-Bulgarian Chiliandari and Zographu, are occupied exclusively by Greek monks. The large skete of St Andrew and some others belong to the Russians; there are also Rumanian and Georgian sketes. The great monastery of Rossikon, which numbers nearly a thousand inmates, has been under a Russian abbot since 1875; it is regarded as one of the principal centres of the Russian politico-religious propaganda in the Levant. The tasteless style of its modern buildings is out of harmony with the quaint beauty of the other monasteries. Furnished with ample means, the Russian monks neglect no opportunity of adding to their possessions on the Holy Mountain; their encroachments are resisted by the Greek monks, whose wealth, however, has been much diminished by the secularization of their estates in Greece and Rumania. The population of the Holy Mountain numbers from 6000 to 7000; about 3000 are monks (*καλόγεροι*), the remainder being lay brothers (*κοσμικοί*). The monasteries, which are all fortified, generally consist of large quadrangles enclosing one or more churches; standing amid rich foliage, they present a wonderfully picturesque appearance, especially when viewed from the sea. Their inmates, when not engaged in religious services, occupy themselves with husbandry, fishing, and various handicrafts; the standard of intellectual culture is not high. A large academy, founded by the monks of Vatopedi in 1749, for a time attracted students from all parts of the East, but eventually proved a failure, and is now in ruins. The muniment rooms of the monasteries contain a marvellous series of documents, including chrysobulls of various emperors and princes, sigillia of the patriarchs, typica, irades, and other documents, the study of which will throw an important light on the political and ecclesiastical history and social life of the East from the middle of the 9th century. Up to comparatively recent times a priceless collection of classical manuscripts was preserved in the libraries; many of them were destroyed during the War of Greek Independence by the Turks, who employed the parchments for the manufacture of cartridges; others fell a prey to the neglect or vandalism of the monks, who, it is said, used the material as bait in fishing; others have been sold to visitors, and a considerable number have been removed to Moscow and Paris. The library of Simopetra was destroyed by fire in 1891. There is now little hope of any important discovery of classical manuscripts. The codices remaining in the libraries are for the most part theological and ecclesiastical works. Of the Greek manuscripts, numbering about 11,000, 6618 have been catalogued by Professor Spyridon Lambros of Athens; his work, however, does not include the MSS. in some of the sketes or those in the libraries of Lauri and Vatopedi, of which catalogues (hitherto unpublished) have been prepared by resident monks. The Slavonic and Georgian MSS. have not been catalogued. Apart from the illuminated MSS., the mural paintings, the mosaics, and the goldsmiths' work of Mount Athos are of infinite interest to the student of Byzantine art. The frescoes in general date from the 15th or 16th century: some are attributed by the monks to Panselinos, "the Raphael of Byzantine painting," who apparently flourished in the time of the Paleologi. Most of them have been indifferently restored by local artists, who follow mechanically a kind of hieratic tradition, the principles of which are embodied in a work on iconography by the monk Dionysius, a pupil of Panselinos. The same spirit of conservatism is manifest in the architecture

of the churches, which are all of the mediæval Byzantine type.

(J. D. B.)

Macerata, a town, bishop's see, and capital of the province of the same name, the Marches, Italy, between the Apennines and the Adriatic, 43 miles by rail south of Ancona. It has a fine prefecture (formerly palace of the Gonzaga), a town hall, a university (1290), with a law faculty and special classes in medicine (11 professors, 310 students, in 1898), an agricultural school, and an industrial institute. The industries comprise the making of bricks, matches, terra-cotta, and chemicals. Population (1881), 20,249; (1901), 22,806.

Macfarren, Sir George Alexander (1813–1887), English composer, was born in London, 2nd March 1813, and entered the Royal Academy of Music in 1829. A symphony by him was played at an Academy concert in 1830, and another in 1831; for the opening of the Queen's Theatre in Tottenham Street, under the management of his father, in the latter year, he wrote an overture, and various similar works were provided for theatrical and other occasions. His *Cherry Chase* overture, the orchestral work by which he is perhaps best known, was written as early as 1836, and in a single night. On leaving the Academy in 1836, Macfarren was for about a year a music teacher in the Isle of Man. Undeterred by the untoward fate of an opera projected two years before, he wrote another, ultimately called *El Malechor*, which was no more fortunate, three successive managers of theatres becoming bankrupt after they had promised to produce it. In 1837 he was appointed a professor at the Academy, and wrote his *Romeo and Juliet* overture. In the following year he brought out *The Devil's Opera*, one of his best works; for Queen Victoria's marriage in 1840 he joined his father in preparing an "Emblematical Tribute" for Drury Lane. Five years afterwards he became conductor at Covent Garden, producing the *Antigone* with Mendelssohn's music; he finished an opera on *Don Quixote* in the same year, and it was produced under Bunn at Drury Lane in 1846; his

subsequent operas include *Charles II.* (1849), *Robin Hood* (1860), *She Stoops to Conquer* (1864), and *Helvellyn* (1864); a number of other dramatic works were either of such smaller calibre as *Jessy Lea* (1863) (for the German Reeds); *Frey's Gift*, a masque in honour of the prince of Wales's marriage (1863); or works that for one reason or another never saw the light, such as *Allan of Aberfeldy* (1851) and *Kenilworth* (1880), his last opera. A gradual failure of his eyesight, which had been defective from boyhood, resulted in total blindness in 1865, but he overcame the difficulties by employing an amanuensis in composition, and made hardly a break in the course of his work. He was made principal of the Royal Academy of Music in succession to Sterndale Bennett in February 1875, and in March of the same year Professor of Music in Cambridge University. Shortly before this he had begun a series of oratorios, which were the most ambitious, if not the most important, works of his later years: *St John the Baptist* (Bristol, 1873); *Resurrection* (Birmingham, 1876); *Joseph* (Leeds, 1877); and *King David* (Leeds, 1883). In spite of their solid workmanship, and the skill with which the ideas are treated, it is difficult to hear or read them through without smiling at some of the touches of quite unconscious humour often resulting from the way in which the Biblical narratives have been, as it were, dramatized. The list of his other works includes many cantatas, eight symphonies, many overtures, concertos, chamber compositions, anthems, &c. He delivered many lectures of great and lasting value, and his theoretical works, such as the *Rudiments of Harmony*, and the treatise on counterpoint, will probably be remembered longer than many of his compositions. A most important work of his is the first (historical) part of the article Music in the earlier volumes of this Encyclopædia, ninth edition. He was knighted in 1883, and died suddenly in London, 31st October 1887.

An excellent memoir by H. C. Banister appeared in 1891.

(J. A. F. M.)

MacGregor, John ["Rob Roy"] (1825-1892), Scottish canoeist, traveller, and philanthropist, son of General Sir Duncan MacGregor, K.C.B., was born at Gravesend, 24th January 1825, and educated at different schools, according to his father's changes of station. He combined a roving disposition with a natural taste for mechanics and for literature. In 1839 he went to Trinity College, Dublin, and in 1844 to Trinity, Cambridge, where he was a wrangler. He was called to the bar in 1851, but being financially independent, he did not pursue his profession. He travelled a great deal in Europe, Egypt, Palestine, Russia, Algeria, and America, and between 1853 and 1863 was largely occupied with researches into the history and methods of marine propulsion. He was the pioneer of British canoeing. In 1865 he started on a first long canoeing cruise in his "Rob Roy" canoe, and in this way made a prolonged water tour through Europe, a record of which he published in 1866 as *A Thousand Miles in the Rob Roy Canoe*. This book, which was succeeded by others of the same sort, made MacGregor and his canoe famous. He made similar voyages in later years in the North Sea and in Palestine, and was the author of the article on CANOEING in vol. iv. of this Encyclopædia (ninth edition). He did not, however, confine his energies to travelling. He was active in charity and philanthropic work, one of the founders of the Shoe-black Brigade, vice-president of the Ragged School Union, honorary secretary of the Protestant Alliance, and a supporter of the Open-air Mission, British and Foreign Bible Society, and Reformatory and Refuge Union. In 1870 and again in 1873 he was elected on

the London School Board. He died at Boscombe, 16th July 1892.

Machine Guns.—In the article GUN-MAKING in vol. xi. of this work (ninth edition) will be found a description of the machine guns in use in the British service up to the year 1880. It will be noticed that all of them are worked by hand-power applied to a lever or winch-handle, the motion of this lever being translated by suitable mechanism into those by which the cartridges are loaded, fired, extracted, and ejected—the cycle continuing as long as the lever is worked and there are cartridges in the "hoppers" which feed the gun. In the modern "automatic" machine gun the loading, firing, extracting, and ejecting are all performed automatically by the gun itself, either by the recoil of its barrel, or by a small portion of the gases of explosion being allowed to escape through a minute hole in the barrel near the muzzle. It is obvious, therefore, that as the due performance of the cycle of operations above mentioned is dependent on the explosion of the cartridge, a "hang-fire" merely causes a delay and nothing more, whereas, with a hand-worked gun, a cartridge which has "hung fire" must be extracted, and may explode in and derange the mechanism. Again, since no hand-power is applied, no disturbance of aim, due to this cause, can arise. Guns of this class can be worked by one man, although two at least are generally employed.

The idea of using the recoil, or a portion of the gases of explosion, for the working of the breech mechanism is by no means new, the latter system having been proposed and patented (certainly in a very crude and probably unworkable form) by Mr. afterwards Sir Henry, Bessemer in 1854; but whatever might be discovered by a search in old patent and other records or in museums, there can be no doubt that Sir Hiram Maxim was the first to produce a finished automatic gun of practical value. His patents in connexion with this particular class of weapon date back to 1884, and his gun on the recoil system was, after extensive trials, adopted into the British army in 1889 and into the navy in 1892. It is very possible that Bessemer's idea did not bear fruit earlier because the fouling left by the old forms of "black" or smoky powders was apt to clog the moving parts and to choke any small port. With the modern smokeless powders this difficulty does not arise.

The Maxim gun, as will be seen from Figs. 1 and 2, consists of two parts, the barrel casing (*a*) and breech casing (*d*), secured firmly together. The former (*a*), which is cylindrical in form, contains the barrel (*b*), and the water surrounding it to keep down the very high temperature attained by rapid fire, and the steam tube (*c*), which by the action of a sliding valve allows of the escape of steam but not of water. The barrel has asbestos packings at its front and rear bearings in the casing, which allow of its sliding in recoil without the escape of water. The breech casing (*d*) is a rectangular oblong box, and contains the lock and firing mechanism. At its rear end it has handles (*e*) by which the gun is directed, and the thumb-piece (*m*) by which the trigger is actuated. Its top is closed by a lid, hinged at (*i*) in front, and provided with a spring catch. At its front is a recess holding the feed-block (*f*) through which the belt of cartridges (*g*) is fed to the gun. Attached to the rear of the barrel (*b*) on either side are two side plates (*h*), between which in guides O works the aggregation of parts D, F, J, K, L, P, T, and V, which constitute the lock, and (in bearings) the crank-axle E, crank E', and connecting rod I. (See Figs. 2 to 6.)

The connecting rod I joins the lock and crank, being attached to the side levers J of the former by means of the "interrupted" screw U, which enables the lock to be readily detached as a whole, and removed from the mechanism.

The crank-axle E extends through both sides of the breech casing (*d*), slots (*k*, Fig. 1) allowing it a longitudinal movement of about an inch. To its left-hand end, outside the breech casing, is attached the fusee chain Y of the recoil spring X (see dotted lines in Fig. 1), and to its right-hand end a bell trunk lever, B B'; the arm B, which terminates in a knob, being turned by the crank handle, the arm B' working against the buffer stop C.

In Figs. 2, 3, and 5 the breech is shown closed, and it will be noticed that the crank pin *l'* is *above* the straight line joining the axis of the barrel, the striker *T*, and the crank axle *E*. As the crank is prevented from further movement *upwards* by the crank handle *B* taking against the check-lever *G* (Fig. 1), it is clear that the pressure on discharge of the cartridge cannot cause the crank axle to rotate, and so open the breech as shown in Figs. 4 and 6.

The withdrawal of the lock and opening of the breech are effected as follows:—The *total* travel in recoil of the barrel is about one inch, but on discharge, the barrel, the side plates, and lock all recoil *together* for about a quarter of an inch without any disturbance of the locking as explained above, and by the time this short travel is completed the *bullet has left the muzzle*. The arm *B'* of the crank handle then engages the buffer stop *C* and causes the crank axle *E* to

Figs. 1 and 2.—Mechanism of Maxim Gun.

rotate and the crank *E'* to *fall* and so draw back the lock from, and open, the breech. At the same time the fusee chain *Y* is wound up round the left-hand end of the crank axle *E* and the spring *X* extended. In the meantime the knob of the buffer handle *B* swings over, and just as the lock reaches its rearmost position (as in Figs. 4 and 6) strikes the flat buffer spring *H*, and, rebounding, assists the crank in revolving in the reverse direction; the spring *X* also contracts, and, unwinding the fusee chain, draws back the lock again, and closes the breech, a fresh cartridge having been placed in the barrel as explained below.

The extractor *D* (see Figs. 3 to 6) which performs the operations of inserting, extracting, and ejecting the cartridges, travels vertically in guides on the face of the lock. Projecting outwards from each side of its top are horns *N* (Figs. 3 and 4). These travel round the edges of the cams *M* (Fig. 2) situated on each side of the breech casing, and in conjunction with the spring *W* (Fig. 2), compel the top of the extractor to take the path shown by the dotted lines and arrows in Figs. 3 to 6.

The extractor (Figs. 5 and 6) is recessed to take a movable plate (*u*) termed a "gib," behind which is a spring (*v*). In the face of the gib is a recess (*w*) into which the base of a cartridge can just enter. On either side of the gib the face of the extractor has under-cut flanges, open at the top and bottom, between which the base of a cartridge can fit the rim, being held in the undercuts (Figs. 3 and 4).

It is clear from this arrangement that the base of the cartridge having been introduced between the flanges at the top of the extractor, can be pushed down, the spring (*v*) yielding, till arrested at the recess (*w*); and, as the lower edges of this recess are slightly sloped, further pressure will make it leave the recess (*w*) and slide over the face of the gib, leave it, and take up a position in front of the hole for the point of the striker (*x*), being now only prevented from slipping out of the extractor by the extractor spring (*y*). If this last be clear of the extractor stop (*z*) it will yield to pressure and the cartridge will be free. This is the action in the gun except

FIG. 3.—Maxim Gun Mechanism.

The gun is fired by means of the trigger *F*, which is actuated by the projection (*l*) on the trigger bar (*S*), the latter being drawn back when the button (*m*) on the push-lever (*n*) is pressed forwards. If, therefore, the button be kept permanently pressed, the projection (*l*) will always lie in the path of the trigger *F* just as the lock reaches its forward position, and the breech is closed, and the gun will fire automatically, and continue to do so as long as there are cartridges in the belt.

The loading, extraction, and ejection of the cartridges are effected as follows:—The left-hand side-plate is extended forwards a little beyond the breech, and communicates the reciprocating motion of the barrel to a lever on the feed-block, which causes the cartridges in the belt to be fed forward one by one by a "step-by-step" pawl action, the cartridge which is next to be taken from the belt being arrested exactly above the breech, the ejector-tube *Q* being below in the same vertical plane.

that the cartridge is held firm and the extractor pushed against it.

In Fig. 4, the extractor holds a cartridge (*r*) and a fired case (*q*) ready to be pushed into the empty breech and ejector-tube *Q* respectively. In the latter there is already a fired case (*p*), which will be driven by the fired case (*q*) beyond the ejector spring *R*. As soon as the lock reaches the face of the breech, the cartridge (*r*) and case (*q*) are deposited in the breech and ejector-tube respectively, and the extractor *D* rises under the action of the levers *L* and *J*, slides, as already explained, by the bases of the cartridges (*r*) and case (*q*), and then over the base of the cartridge (*s*) in the belt (*g*). Assuming the push-lever (*n*) to be pressed, the gun fires immediately this has occurred, and the bullet of the cartridge (*r*) is expelled. The position is now that shown in Fig. 3. The barrel now recoils and the lock is withdrawn, taking with it the fresh cartridge (*s*) from the belt and the now fired case (*r*). The extractor travels horizontally for a time and then drops (as shown by the dotted line

and arrows), assuming the position shown in Fig. 6, which is exactly similar to that in Fig. 4 but with different cartridges; continuing the action, the position shown in Fig. 5 is arrived at. It will thus be seen that each cartridge makes two complete journeys with the extractor; the first as a live cartridge from the belt to the breech, the second from the breech to the ejector-tube, the forward journey being always on a lower level than that of the backward one. The sections in Figs. 5 and 6 clearly show the cocking and firing mechanism and the safety arrangement. The lock is cocked, after firing, by the arm of the "tumbler" K, being pressed down by the side lever J as it swings down when following the crank E'. Safety against firing before the breech is closed is provided by the projection on the safety lever V, which does not clear the striker T until lifted by the side lever J at the top of its travel, that is, when the crank E' has passed the axial line as already explained.

The lock in its rearmost position is kept in place by the block Z on the underside of the cover of the breech casing. When in this position it is clear of the guides O on the side plates, and if the cover be opened, it can be turned up, unscrewed by a turn through an eighth of a circle (the screw-thread U being interrupted in four places) and removed. To

The Hotchkiss gun, Figs. 9 to 12, which has been adopted by the French army and navy, depends for its action on the use of a small portion of the gases of the cartridge itself. The barrel A is

FIG. 4.—Maxim Gun Mechanism.

firmly attached to the receiver or frame B, the latter containing the breech and firing mechanism. Under the barrel A, and communicating with it by a port (c) near the muzzle is a cylinder or tube C. When the gun is fired, and the bullet has passed the port (c), a portion of the gases of explosion pass into the cylinder C and drive back the piston F contained in it, a lug on the under part of the piston compressing the spring M, the latter, when the trigger N is pulled, driving back the piston again. The reciprocating motion of the piston performs all the processes of loading and firing the gun, and the action is continuous as long as the trigger is kept pressed back.

The piston F, enlarged and suitably shaped at the rear, actuates the breech-block H and firing pin or striker J; and, by suitable cam grooves (f) at about the centre of its length, works the larger feed-wheel U of the feed-box S; the smaller wheel U on the same axis in turn imparting a step-by-step motion to the metal feed-strips (see Fig. 12), each containing 30 cartridges, so that fresh cartridges are placed one by one before the face of the breech-block ready to be pushed into the breech when the fired cartridge has been extracted and ejected.

On the under surface of the piston F, in rear, is a recess or sear (f) in which the nose of the trigger N engages, holding back the

prepare the gun for firing, the crank handle is pushed over by hand to the buffer-spring, thus withdrawing the extractor, and held in this position; the tongue on the end of a filled belt is then pushed through the feed-block from the left and pulled as far as it will go from the opposite side. This places a cartridge above the breech ready to be seized by the extractor. The crank handle is now released and the lock flies forwards. The crank handle is now again pushed over and let go, and the first cartridge thus taken from the belt and placed in the breech. The gun is ready to fire.

To remove a partially filled belt, the crank handle must be pushed over, thus freeing the extractor from the belt, and the latter withdrawn after pressing a spring catch under the feed block which releases the pawls. The gun now has two live cartridges in it—both in the extractor. Letting go the crank handle, one of them is deposited in the ejector-tube, and again pushing over and letting go the crank handle does the same with the second.

Figs. 7 and 8 show the feed-block and method of packing the cartridge belts. The greatest number usually carried in a belt is 250.

The gun is sighted to 2500 yards and has a folding tangent sight as shown. Its weight varies from 50 to 60 lb, and it can fire about 450 rounds per minute.

The diagrams have been made from drawings, by permission of Messrs Vickers, Sons, and Maxim.

FIG. 5.—Maxim Gun Mechanism.

FIG. 6.—Maxim Gun Mechanism.

piston when it has been driven back by the gases. As already stated, a lug on the under surface just in rear of the cam (f) engages with the front of the mainspring.

Taking first the position shown in Fig. 10 with the breech closed

and locked, and the cartridge fired, it will be seen that the breech is locked by the *upper cam* (f^1), on the end of the piston F, having caused the movable locking-dog (h) to fall and bear against the recoil blocks Z (see Fig. 9 also) on the walls of the receiver or frame B. Consequently the breech is not unlocked until the piston has moved sufficiently to the rear for the *lower cam* (f^2) to lift the locking-dog (h) clear of the recoil blocks Z. As the piston F is not actuated by the gases until the bullet has passed the port (c), and then has to move a short distance before the locking-dog is raised, the bullet, travelling at some 2000 feet per second, is clear of the muzzle *before* the breech is unlocked.

Fig. 7.—Maxim, Feed-block.

As the piston continues to recoil it draws back the striker J and then the breech-block H, and is then caught and retained by the engagement of the sear

(f^3) with the trigger N, and the position assumed is that shown in Fig. 9.

From the head or nose-piece I of the breech-block projects the

claw K of a spring extractor which, as the cartridge is pushed home by the breech-block, rides up over the rim of rimmed, or over the base into the grooves of rimless cartridges, and thus attaches itself

Fig. 8.—Maxim, Cartridge-packing.

to the cartridge, extracting the fired case when the breech-block is withdrawn. Ejection of the fired case is effected by means of the ejector L (Fig. 11) which catches against the base of the case, on the opposite side to the extractor claw, and so throws it sideways

HOTCHKISS AUTOMATIC MACHINE GUN.

Figs. 9, 10, 11.—Hotchkiss Gun Mechanism.

through the oblong-pointed opening in the receiver just in rear of the breech (see Fig. 9).

The platform on the top of the feed-box through which the teeth of the smaller feed-wheel U project, and on which the feed-

Fig. 12.—Hotchkiss Cartridge Feed-strips.

strips rest, lies *below* the axial line of the breech-block H, so that the face or nose-piece I of the latter only engages a *portion* of the base of the cartridge in the feed-strip as it pushes the cartridge into the breech, the bullet of the cartridge being guided into the breech by the incline at the opening of the latter. This point should be specially noted, the object of the arrangement being to enable the under surface of the breech-block to clear the clips which hold the cartridges in the feed-strips. The cartridge

therefore, being extracted in the line of the axis of the block, is ejected through an opening *above* its plane of entry in the feed-strip.

Returning to the position shown in Fig. 9, if the trigger be pulled, the compressed spring M reacts and drives the piston forwards, carrying the breech-block with it, the latter in turn driving a cartridge in front of it out of the feed-strip. When the block and cartridge are home, and *not till then*, the piston completes its travel, the upper cam (f^1) locking the dog (h), and the firing pin protrudes and fires the cartridge. Anything, therefore, which prevents the breech-block from being home against the breech, or the locking-dog from falling in front of the recoil blocks Z, renders firing of the cartridge impossible. Clearly if the trigger be kept depressed the action becomes automatic.

A *special feature* of this gun is the absence of a separate spring to actuate the firing-pin; the recoil spring M performing this function, in addition to that of driving the piston forwards.

The feed-strips have holes in them in which the teeth of the smaller feed-wheel U engage. The engagement of this feed with the piston F can be released by pulling out the feed arbor W, so that the strips can be removed at any time.

Under the feed-box is a spring stop V, which is depressed when there is a feed-strip in the block, but, when this is not the case, engages with and holds back the piston F when in its rear position. When, therefore, the last shot in a feed-strip has been fired, the stop V at once acts and holds the piston and block ready for a fresh feed-strip to be inserted. As the stop V acts quite independently of the trigger, this action takes place even if the

trigger be still depressed after the last cartridge in a strip has been fired.

To cock the gun, when in the locked position, a cocking handle G is provided. This has a long arm projecting to the front with a catch which takes against the front of the lug on the under side of

can be turned so as to enter the semicircular slot just in front of the sear (f), and so hold back the piston when in the cocked position.

Radiation of the heat, generated in the barrel by rapid fire, is facilitated by the radiator (a), which consists of rings on the barrel close to the breech, which offer an increased surface to the air.

The gun is sighted to 2000 yards, with the ordinary flap back-sight, weighs about 53 lb, and can fire from 500 to 600 rounds per minute.

The diagrams have been made from drawings, by permission of the Hotchkiss Ordnance Company.

The Colt automatic gun, which has been adopted by the American army and navy, depends for its action, similarly to the Hotchkiss, on the escape of a small portion of the gases of explosion through a port in the barrel a short distance from the muzzle. Figs. 13 and 14 give a plan, and side elevation with the left side plate removed, respectively. Into the recess in the barrel (92) just below the port fits the piston (35), capable of slight motion round the pivot (36), by which it is attached to the gas lever (29). The latter is a bell crank lever pivoted at (34), its short arm being attached at (46) by a pivot to a long link with a cross head, termed the retracting connexion (45). This link extends from a point close to the figures (44), where the arms of the cross head bear against the ends of two long spiral retracting springs, (37) and (38), contained in two tubes, (39) and (40), which are slotted for a few inches of their length to allow the cross head to follow up and compress the springs. (Only (38) and (40) are shown, (37) and (39) lying in the same plane of projection.)

When the gun fires, and the bullet has passed the port, the gases drive the piston (35) and gas lever (29) downwards, and the momentum imparted causes them to swing back round the pivot (36), as shown by the dotted circle. The gas lever is brought up now by the bottom plate (91); and the retracting springs, compressed by the cross head of the long link (45) owing to the forward motion of the short arm of the gas lever, react, and drive the gas lever into its forward position again.

The rotary movement of the gas lever is converted into a reciprocating movement of the slide (86) by means of the gas lever connexion rod (31) pivoted at (32) to the gas lever, and at (87) to the slide.

The slide (86) is a nearly flat bar, travelling in guides in the receiver, extending from (14) to (87). It is slotted completely through longitudinally for nearly the whole of its length, this slot affording an opening through which work the cartridge extractor (82) and carrier (21). At its rear end it engages by means of a pin (14) in a cam slot (97) in the bottom rib of the bolt (13), and at (83) it bears the pivot of the cartridge extractor (82). Its rear end is enlarged below to form a cam lug (98), and on its right side are two projections (95) and (96), which work the feed lever (66).

The feed wheel (61), over which passes the belt containing the cartridges, is actuated by a pawl "step-by-step" gear by means of the feed lever (66).

The carrier (21) is a long trip lever pivoted at (22), and provided with a spring dog (23) pivoted at (24).

The bolt (13) is a cylinder with a guide rib extending from its under surface. It is actuated by the slide by means of the pin (14) and cam slot (97) as already stated, and is bored through to take the striker or firing pin (18). The rear end of the latter projects slightly beyond the rear face of the bolt, being retained in this position by the spring (19). When this projecting end is pushed into the bolt, the point protrudes from the front of the bolt and fires the cartridge. The bolt, when the breech is locked, is held firm by two recoil blocks on the receiver (not shown) as is explained later. At the front of the bolt is an extractor (15) with a spring claw for extracting the fired case. (This is of course quite distinct from the cartridge extractor (82)). Ejection is effected by means of an ejector projecting into the path of the fired case in a manner similar to that employed in the Hotchkiss gun as already described.

The firing of the gun is performed by the cylindrical hammer (6) hollowed out in rear to contain the mainspring (7). When pushed back and cocked as shown in Fig. 14, it is held during a portion of the operations of the mechanism by two detents working independently of each other—the sear (10) and the nose of the trigger (8). The former is automatically released by a trip lever (not shown) as soon as the breech is locked, leaving the hammer held by the trigger only. This is the position shown in Fig. 14. The necessity for the two detents is explained later.

The hammer, when cocked, can also be permanently locked by the handle lock (2) actuated by a thumb piece on the outside of the receiver. The air compressed in rear of the hammer, as the latter is driven back, passes through the tube (99) to the breech; and a puff of air is therefore blown through the barrel after every shot, clearing out any loose fouling, or grains of unconsumed powder, from the cartridge chamber, and assisting to an appreciable extent to keep down the temperature of the barrel.

Figs. 13 and 14.—Colt Automatic Gun Mechanism.

the piston. To prepare the gun for action the gun is cocked, and a feed-strip is pushed into the feed-block.

The pressure of the gas on the piston is regulated by the regulator screw D, by means of which the space in the cylinder C in front of the piston F can be reduced or increased.

A safety lock R is furnished, which is a "half round" pin which

Taking the position shown in Fig. 14, the hammer is only held back by the trigger nose, the sear (10) having been released as stated above. A belt of cartridges (not shown) has been placed on the feed-wheel, and the cartridge next to be used after the one (not shown) now in the breech has its rim (or base with rimless cartridges) just above the hook on the extractor (82). If now the

FIG. 15.—Colt Gun mounted.

trigger be pulled, the hammer flies forwards, strikes the protruding end of the firing pin, and the cartridge fires; the gases cause the gas lever to swing round and drive back the slide. The pin (14) working in the cam groove (97) causes the rear of the bolt to rise and clear itself from the recoil blocks (not shown) on the receiver, and then to move rearwards horizontally, driving the hammer back until the latter is caught and held by the sear and trigger. In the meantime the extractor (82) has pulled a cartridge from

FIG. 16.—Hotchkiss Gun mounted.

the belt, and, assisted by two spring cartridge guides (80) and (81), of which only (80) is shown, deposits it on the carrier (21); the projection (95) strikes the feed-lever (66), and moves the feed mechanism so as to prepare to revolve the feed-wheel and place a fresh cartridge ready for the next round; and, as the slide completes its travel backwards, the cam (98) strikes the dog (23) and slightly depresses it (the spring (25) yielding), the carrier and cartridge on it consequently rising a little and falling again (this latter action is incidental only to the form of the parts, and is not a necessity).

The retracting springs now react and pull the slide forwards; the cam (98) strikes the dog (23), which, as the spring arrangement is of the "non-return" class, does not yield but is depressed, and the front of the carrier and the cartridge on it are therefore raised sharply, and the latter placed in the path of the bolt. The bolt being now pulled forwards, the cartridge is driven off the carrier into the breech, and the bolt locked by the pin (14), causing the bolt to drop in front of the recoil blocks; the carrier is pushed down flat by the advance of the cam lug (98), the trip releases the sear (10), and the projection (96) pushes back the feed lever, completing the action of feeding a fresh cartridge forward. The position shown in Fig. 13 is now resumed.

It is clear that were the trigger kept permanently pulled the gun would fire immediately the bolt was locked and the sear (10) depressed, and the action would become automatic.

The object of two detents, though now probably obvious, may here be explained. The whole action of the gun depends upon the hammer, after it is pushed back by the bolt, being held back until the bolt has gone completely forwards and locked the breech. If only the trigger detent existed, and that were kept pressed down, the hammer, after being pushed back by the bolt, would immediately follow up the latter, and might fire the cartridge prematurely, or fail to fire it at all; hence the use of the sear in addition to the trigger.

To cock the lock, or work the mechanism by hand, the gas lever is pulled round by the pin (30) provided for the purpose, and by this means the gun is prepared for firing. A brass tongue on the end of the belt is pushed through the opening above the feed-wheel and then pulled from the other side of the gun as far as it will go. This places a cartridge in front of the extractor, and if the gas lever be now pulled right back and let go, this cartridge is placed in the breech as already described, and the gun is ready for firing. If it be desired to remove a belt from the feed, a button (68) is pressed and the feed-wheel is then free to revolve backwards.

The gun is sighted with the ordinary rifle pattern sights, up to 2000 yards or more if required. It weighs about 40lb, and can fire about 400 rounds per minute as usually adjusted, though this rate can be increased. There is no means of altering the gas pressure in the field as with the Hotchkiss.

The diagrams have been made from drawings, by permission of the Colt Gun Company.

Comparing the principle of employing a recoiling barrel with that of using a portion of the gas, the advantages of the former are that the recoil is made to do useful work instead of straining the gun and mounting in its absorption; the latter system, however, has undoubtedly the advantage in simplicity of mechanism (the Hotchkiss is extraordinarily simple in construction for an automatic gun), and in the large margin of power for working the mechanism with certainty in all conditions of exposure to climate, dust, and dirt. While inferior in this respect, it is nevertheless the fact that the Maxim has proved itself in the field to be a very efficient and powerful weapon.

The great difficulty which has to be met in all single-barrel machine guns is the heating of the barrel. How great this heat is may be gathered from the fact that the $7\frac{1}{2}$ pints of water in the water-jacket of the Maxim gun are raised to boiling point by 600 rounds of rapid fire,—i.e., in about $1\frac{1}{2}$ minutes,—and if firing be continued, about $1\frac{1}{2}$ pints of water are evaporated for every 1000 rounds. Assuming that the operation is continuous, the rate of waste of energy due to heat expended on the water alone is equivalent to about 20 horse-power (294 foot tons per minute). The water-jacket acts well in keeping down the temperature of the barrel; but apart from the complications entailed by its use, the provision of water for this purpose is at times exceedingly troublesome on service. In the Hotchkiss and Colt guns, which have no water-jacket, an attempt is made to meet the heating, in the one by the radiator, and in the other by a very heavy barrel.

For military and naval purposes the automatic gun is, under certain conditions, of great value. For the sweeping of defiles, the warding off of the attacks of masses of men in close formation, or the pouring in of an immense number of bullets into a rapidly advancing torpedo boat, it is a most valuable weapon, and in addition its moral effect is

great; but against men scattered over a wide front there is no doubt it is very wasteful for the effect obtained. It is by no means easy to proportion the fire to the target, as there are only two rates of fire, viz., rapid automatic and slow single shots. To fire a single shot requires some practice, since the gun will fire some 7 shots in one *second*, and to press the trigger and remove the finger or thumb instantly, and at the same time be ready to traverse to a fresh target, requires considerable skill. The result of these difficulties is that the target

Mackay, a seaport town, Queensland, Australia, in the county of Carlisle, on the Pioneer river, 625 miles north-west of Brisbane. The harbour is not a good one. Sugar, tobacco, and coffee thrive in the district, which is dotted with hundreds of sugar-farms. There are several important sugar-mills, and one of these, the largest in Queensland, is capable of an annual output of 8000 tons. Rum is distilled. Workable coal is found in the district. This is the port of the Mount Orange and Mount Gott-hart copper mines, and the Mount Britten and Eungella gold-fields. It is a calling station for the Queensland Royal Mail steamers. Population (1901), 5157.

FIG. 17.—Maxim Gun mounted.

when struck is often riddled with bullets, when a few or even one would have sufficed. The aiming of the gun, when rapid fire is taking place, is also difficult even on firmly fixed mountings, as the vibration, due to the rapidly repeated similar impulses, is very great. Figures 15 to 17 show these guns on three classes of mounting which are in common use.

(H. W. B.)

Mackay, Charles (1814–1889), Scottish writer, was born at Perth, 27th March 1814. He was educated at the Caledonian Asylum, London, and in Brussels; and in 1830, being engaged as private secretary to a Belgian ironmaster, he began writing articles and verses for local newspapers. Returning to London, he devoted himself to literary and journalistic work, and was attached to the *Morning Chronicle* (1835–44). He published a book called *Memoirs of Extraordinary Public Delusions* (1841), and gradually made himself known as an industrious and prolific journalist. In 1844 he was made editor of the *Glasgow Argus*, and two years later was given the degree of LL.D. by the university. His literary reputation was made by the publication in 1846 of a volume of verses, *Voices from the Crowd*, some of which (among them "The Good Time Coming") were set to music by Henry Russell and became very popular. In 1848 Mackay returned to London and worked for the *Illustrated London News*, of which he became editor in 1852. In it he published a number of songs, set to music by Bishop and Russell, and in 1855 they were collected in a volume; they included the popular "Cheer, Boys! Cheer!" It was as a songwriter that he was best known, but he was also a prolific author in prose, and after his severance from the *Illustrated London News* in 1858 he started two periodicals which turned out unsuccessfully, and also acted as special correspondent for *The Times* in America during the Civil War from 1862 to 1865. Among his publications must be mentioned the well-known *Thousand and One Gems of English Poetry* (1867). Mackay died in London, 24th December 1889. His son, **ERIC MACKAY** (1851–1899), is known as a writer of verse, particularly by his *Love Letters of a Violinist* (1886).

and its business streets are paved largely with bricks and granite blocks. It is in the midst of the coking coal region, and has an abundance of natural gas. Its industries consist mainly in iron and steel manufacture. In 1890 it contained a total of 118 manufacturing establishments, with a capital of \$10,979,812, employing 6292 men, and with a product valued at \$17,432,721. Not less than $\frac{1}{5}$ ths of this consisted of iron and steel goods. The assessed valuation of real and personal property in 1900 (on a basis in the case of the former of about three-fourths of the full value) was \$17,604,560, the net debt of the city was \$705,148, and the rate of taxation \$20.25 per \$1000. Population (1880), 8212; (1890), 20,741; (1900), 34,227, showing a rapid rate of increase, due to the development of the city's manufactures of iron and steel.

M'Kees Rocks, a borough of Allegheny county, Pennsylvania, U.S.A., on the south bank of the Ohio river, opposite Allegheny city, in the south-western part of the state. It is entered by the Pittsburg and Lake Erie, and the Pittsburg, Charleston, and Youngstown railways. The leading industries of the town are iron and glass manufacturing. Population (1890), 1687; (1900), 6352, of whom 1264 were foreign-born and 20 were negroes.

Mackenzie, a river of the North-West Territories, Canada, discharging the waters of Great Slave Lake into the Arctic Ocean; discovered and first navigated by Alexander Mackenzie (1789). It has an average width of one mile; an average fall of six inches to the mile; an approximate discharge, at a medium stage, of 500,000 cubic feet per second; and a total length, including its great tributary the Peace, of 2350 miles. The latter rises, under the name of the Finlay, in the mountains of British Columbia, and flows north-eastwards and then south-eastwards, in the great intermontane valley that bounds the Rocky Mountains on the west, to its confluence with the Parsnip. From the confluence the waters of the combined rivers, now called

the Peace, flow eastwards through the Rocky Mountains, and then north-eastwards to unite with the river which discharges the waters of Lake Athabasca; thence to Great Slave Lake it is known as Slave river. The principal tributaries of the Peace are: Omineca, Nation, Parsnip, Halfway, North Pine, South Pine, Smoky, Battle, and Loon rivers. The only considerable streams draining into Lake Athabasca are the Black, William, and Athabasca, and into Great Slave Lake the La Martre, Yellowknife, Lockhart—draining Aylmer, Clinton-Colden, and Artillery lakes—Du Rocher, Slave, and Hay. The principal tributaries of the Mackenzie are the Liard, 650 miles long, which rises near the sources of the Pelly—west of the Rocky Mountains—and breaks through that range on its way to join the parent stream, Great Bear river, which discharges Great Bear Lake, Nahanni, Dahadinni, Arctic Red and Peel rivers. The Mackenzie and its continuation, Slave river, are navigable from the Arctic Ocean to Fort Smith, a distance of over 1200 miles, and between the latter and the head of Lesser Slave Lake, a further distance of 625 miles, there is only one obstruction to navigation, the Grand Rapids near Fort McMurray. The Mackenzie is navigable from about 10th June to 20th October, and Great Slave Lake from about 1st July to the end of October.

Mackenzie, Alexander (1822–1892), Canadian statesman, was born in Perthshire, Scotland, 28th January 1822. His father was a builder, and young Mackenzie emigrated to Canada in 1842 and worked in Ontario as a stone-mason, setting up for himself later as a builder and contractor at Sarnia with his brother. In 1852 his keen interest in questions of reform and Liberal politics led to a connexion with a local paper, which brought him to the front, and in 1861 he became a member of the provincial parliament, where he at once made his mark and was closely connected with the Liberal premier, George Brown. He was elected for Lambton to the first Dominion House of Commons in 1867, and soon became the recognized leader of the Liberal Opposition; from 1871 to 1872 he also sat in the Ontario provincial assembly. In 1873 his attack on Sir John Macdonald's ministry with regard to the Pacific railway charter resulted in their defeat, and Mackenzie formed a new Government, taking the portfolio of public works and becoming the first Liberal premier of Canada. He remained in power till 1878, when industrial depression led to a reaction against the Liberal free-trade policy and enabled Sir John Macdonald to return to office on a protectionist programme. In 1875 Mackenzie paid a visit to Great Britain, and was received at Windsor by Queen Victoria; he was offered a knighthood, but declined it. After his defeat he suffered from failing health, but though he resigned the leadership of the Opposition, he retained a seat in parliament till his death at Toronto on 17th April 1892. (See also CANADA.)

Mackenzie, Sir Alexander Campbell (1847—), British composer, son of an eminent Edinburgh violinist and conductor, was born 22nd August 1847. On the advice of a member of Gung'l's band who had taken up his residence in Edinburgh, one Bartel, the young Mackenzie was sent for his musical education to Bartel's native place, Sondershausen, where he entered the Conservatorium under Ulrich and Stein, remaining there from 1857 to 1861, when he entered the ducal orchestra as a violinist. It was at this time that he made Liszt's acquaintance. On his return home he won the King's Scholarship at the Royal Academy of Music, and remained the usual three years in the institution, after which he established himself as a teacher of the piano, &c.,

in Edinburgh. He appeared in public as a violinist, taking part in Chappell's quartette concerts, and starting a set of classical concerts. He was appointed precentor of St George's Church in 1870, and conductor of the Scottish Vocal Music Association in 1873, at the same time getting through a prodigious amount of teaching. He kept in touch with his old friends by playing in the orchestra of the Birmingham Festivals from 1864 to 1873. The most important compositions of this period of Mackenzie's life were the Quartette in E flat for piano and strings, Op. 11, and an overture *Cervantes*, which owed its first performance to the encouragement and help of von Bülow. On the advice of this great pianist, he gave up his Edinburgh appointments, which had quite worn him out, and settled in Florence in order to compose. The cantatas *The Bride* (Worcester, 1881) and *Jason* (Bristol, 1882) belong to this time, as well as his first opera. This was commissioned for the Carl Rosa Company, and was written to a version of Merimée's *Colomba* prepared by Dr Franz Hueffer. It was produced with great success in 1883, and was the first of a too short series of modern English operas; Mackenzie's second opera, *The Troubadour*, was produced by the same company in 1886; and his third dramatic work was *His Majesty*, an excellent comic opera, given at the Savoy Theatre in 1897. In 1884 his *Rose of Sharon* was given with very great success at the Norwich Festival; in 1885 he was appointed conductor of Novello's oratorio concerts; *The Story of Sayid* came out at the Leeds Festival of 1886; and in 1888 he succeeded Macfarren as principal of the Royal Academy of Music. *The Dream of Jubal* was produced at Liverpool in 1889, and in London very soon afterwards. A fine setting of the hymn "Veni, Creator Spiritus" was given at Birmingham in 1891, and the oratorio *Bethlehem* in 1894. From 1892 to 1899 he conducted the Philharmonic Concerts, and was knighted in 1894. Besides the works mentioned he has written incidental music to plays, as, for instance, to *Ravenswood*, *The Little Minister*, and *Coriolanus*; concertos and other works for violin and orchestra, much orchestral music, and many songs and violin pieces. The romantic side of music appeals to Mackenzie far more strongly than any other, and the cases in which he has conformed to the classical conventions are of the rarest. In the orchestral ballad, *La Belle Dame sans Merci*, he touches the note of weird pathos, and in the nautical overture *Britannia* his gift of a strong sense of humour stands revealed. If his single comic opera was one of the least successful of the productions at the Savoy Theatre, it was certainly not the least humorous, and it had many passages of real and lasting beauty. In the two "Scottish Rhapsodies" for orchestra, in the music to *The Little Minister*, and in a beautiful fantasia for pianoforte and orchestra on Scottish themes, he has seized the essential, not the accidental, features of his native music.

Mackenzie, Sir Morell (1837–1892), British physician, son of Stephen Mackenzie, surgeon (d. 1851), was born at Leytonstone, Essex, 7th July 1837. After going through the course at the London Hospital, and becoming F.R.C.S. in 1858, he studied abroad at Paris, Vienna, and Pesth; and at Pesth he learnt the use of the newly-invented laryngoscope under Professor Czermak. Returning to London in 1862, he worked at the London Hospital, and took his degree in medicine. In 1863 he won the Jacksonian prize at the Royal College of Surgeons on "Pathology of the Larynx," and he then devoted himself to becoming a specialist in diseases of the throat. In 1863 the Throat Hospital in King Street, Golden Square,

was founded, largely owing to his initiative, and by his work there and at the London Hospital (where he was one of the physicians from 1866 to 1873) Morell Mackenzie rapidly became recognized throughout Europe as a leading authority, and acquired an extensive practice. So great was his reputation that in May 1887, when the Crown Prince of Germany (afterwards the Emperor Frederick III.) was attacked by the affection of the throat of which he ultimately died, Morell Mackenzie was specially summoned to attend him. The German physicians who had attended the Prince since the beginning of March (Gerhardt, and subsequently Tobold, von Bergmann, and others) had diagnosed his ailment on 18th May as cancer of the throat; but Morell Mackenzie insisted (basing his opinion on a microscopical examination by Virchow of a portion of the tissue) that the disease was not demonstrably cancerous, that an operation for the extirpation of the larynx (planned for 21st May) was unjustifiable, and that the growth might well be a benign one and therefore curable by other treatment. The question was one not only of personal but of political importance, since it was doubted whether any one suffering from an incapacitating disease like cancer could, according to the family law of the Hohenzollerns, occupy the German throne; and there was talk of a renunciation of the succession by the Crown Prince. It was freely hinted, moreover, that some of the doctors themselves were influenced by political considerations. At any rate, Morell Mackenzie's opinion was followed: the Crown Prince went to England, under his treatment, and was present at the Jubilee celebrations in June. Morell Mackenzie was knighted in September 1887 for his services, and decorated with the Grand Cross of the Hohenzollern Order. In November, however, the German doctors were again called into consultation, and it was ultimately admitted that the disease really was cancer; though Mackenzie with very questionable judgment, more than hinted that it had become malignant since his first examination, in consequence of the irritating effect of the treatment by the German doctors. The Crown Prince (see FREDERICK III.) became Emperor on 9th March 1888, and died on 15th June. During all this period a violent quarrel raged between Sir Morell Mackenzie and the German surgeons and medical world, both as to the diagnosis and also as to the treatment both before and after the existence of a malignant growth was determined; and the discussion as to the part played by Mackenzie was carried on in a wider circle with much display of feeling after the Emperor's death. The German doctors published an account of the illness, to which Mackenzie replied by a work entitled *The Fatal Illness of Frederick the Noble* (1888), the publication of which caused him to be censured by the Royal College of Surgeons. After this sensational episode in his career, the remainder of Sir Morell Mackenzie's life was uneventful, and he died somewhat suddenly in London, 3rd February 1892. He published several books on laryngoscopy and diseases of the throat. A full discussion of the much-controverted details about Mackenzie's treatment of the Emperor Frederick will be found in *The Times* of 16th October 1888.

(H. CH.)

McKinley, William (1843-1901), twenty-fifth President of the United States, was born in Niles, Trumbull county, Ohio, on 29th January 1843. His ancestors on the paternal side were of Scottish-Irish origin. His great-great-grandfather settled in York county, Pennsylvania, about 1743, whence his great-grandfather, David McKinley, moved to Ohio in 1814. David's son James had preceded him, having gone to Columbiana county,

Ohio, in 1809. William McKinley, father of the President, was the son of this James McKinley, and was born in 1807. He was married in 1829 to Nancy Campbell Allison, of Columbiana county, Ohio, and to them were born nine children, of whom William, the President, was the seventh. In 1852 William McKinley, senior, took his family from Niles, Trumbull county, to Poland, Mahoning county, where the younger William was placed at school in the Union Seminary. At seventeen he was sent to Meadville, Pa., to enter the junior class of Allegheny College. He studied beyond his strength, however, and did not remain to finish his course, but returned to Poland, where for a time he taught in a neighbouring country school. When the Civil War broke out in 1861 he was eighteen years old, and promptly enlisted as a private soldier. He served until the end of the war, and was mustered out with his regiment 26th July 1865, with the brevet rank of major. Army life had changed the rather pale and sickly lad of eighteen into a man of superb figure and health at twenty-two. His regiment was the 23rd Ohio Volunteer Infantry, of which Rutherford B. Hayes was the first colonel. Mr Hayes became a general, and McKinley was for some time a member of his staff. Throughout General Hayes's subsequent career as member of Congress, Governor of Ohio, and President of the United States, he was deeply devoted to the younger man, who was destined to follow a like career as Congressman, Governor, and President.

After the war McKinley returned to Poland, and bent all his energy upon the study of law. He completed his preparatory reading at the Albany (N.Y.) Law School, and was admitted to the bar at Warren, Ohio, in March 1867. He was now twenty-four years old, and ripened and disciplined by experience. On the advice of an elder sister, who had been for several years a teacher in Canton, Ohio, he began his law practice in that place, which was to be his permanent home. He identified himself immediately with the Republican party, and took part in the campaign work on behalf of Grant's Presidential candidature in 1868. In the following year, in spite of the fact that his county (Stark) had almost invariably given Democratic majorities, he was elected prosecuting attorney—a position with which the public careers of many American statesmen have begun. He served in this position for two years, when, failing to obtain re-election by a narrow margin, he devoted himself to his profession, while not relaxing his interest in politics. He was married in 1871 to Miss Ida Saxton, daughter of a banker of Canton.

In 1876 Mr McKinley was elected to Congress. Conditions both in Ohio and in Congress had placed him, and were to keep him so for twenty years, in an attitude of aggressive and uncompromising partisanship. His congressional district was naturally Democratic, and its boundaries were changed two or three times by Democratic legislatures—"gerrymandered," to use an established American expression—for the purpose of so grouping Democratic strongholds as to cause his defeat. But he overcame what had threatened to be adverse majorities on all occasions from 1876 to 1890. Mr McKinley's was a manufacturing district, and his home town of Canton was growing by reason of its industrial enterprises. As a strong believer in the essential relation of the protective tariff policy to the growth of American industries, Mr McKinley soon became known in Congress as one of the most diligent students of industrial policy and questions affecting national taxation. In his first term he took part in the debates over the Wood Tariff Bill, proposing lower import duties. In his second term he was appointed to a position on the Ways and Means Committee. He was

prominent in the debate which resulted in the defeat of the Democratic Morrison Tariff Bill in 1884, and he took an even more notable part in the defeat of the tariff revision project known as the Mills Bill. Soon after the opening of the fifty-first Congress in 1889, Mr McKinley became the chairman of the Ways and Means Committee, and Republican leader in the House. Party feeling was exceptionally intense at that time, and Mr McKinley's name as chairman of the Ways and Means Committee

made him the most conspicuous among the framers of the new Republican tariff measure. His name was popularly attached to it, and he could not evade the storm of controversy which raged in Congress and throughout the country. The Democrats made a concentrated effort to prevent his return to Congress (1890), and they were successful. But Mr McKinley, in the darkest hours of the unpopularity of the McKinley tariff, continued to express his belief in its value. His defeat for Congress was accomplished chiefly by an extraordinary gerrymandering of his district, and he won a moral victory in view of the fact that more Republican votes were cast for him than had ever been cast for any Republican candidate before in the history of the counties which were now aggregated to form the district. The Republicans of the state at once proceeded to champion him and his tariff views by according him the unanimous nomination for the

Governorship. His four years as chief of the executive of Ohio must be regarded as important, largely by reason of the valuable training they afforded in executive as distinguished from legislative work.

Mr McKinley had now become a public man of the first rank. He had been for some time a prominent figure at the quadrennial conventions which bring together the leading Republicans of the entire nation to adopt a platform and nominate a President, and he had also been looked upon in the light of a possible Presidential candidate. In 1888 he was chairman of the platform committee, and leader of the delegation from Ohio, and found a condition prevailing in the convention which would unquestionably have given him the Presidential nomination, but for his absolute refusal to permit his name to be used,

on account of the fact that the Ohio delegation had been instructed to urge the nomination of John Sherman. In 1892 Governor McKinley was the presiding officer of the National Convention; but he had concurred in the opinion that President Harrison ought to be renominated, and this view prevailed, although in spite of all his efforts a large number of delegates cast their votes for him.

It had been supposed that the tariff question would again play a leading part in the campaign of 1896, and

PRESIDENT MCKINLEY.

(From a Photograph by Parker, Washington, D.C.)

such would probably have been the case but for the vast proportions assumed in the West and South by the propaganda for the free coinage of silver. In 1873, preparatory to a resumption of specie payments, the currency and coinage system of the United States had been revised, the silver dollar, which had formerly been the unlimited legal standard jointly with the gold dollar, being demonetized, and the gold dollar becoming the sole monetary standard. Subsequently the great development of silver-mining and the decline in the price of silver bullion gave rise—first among the silver miners, and afterwards among the Western farmers—to a movement for the remonetization of silver. At first this movement was irrespective of party lines. It was generally hoped that a large use of silver in the coinage and currency system with ultimate gold redemption would help the silver bullion market, and that meanwhile European

nations might be persuaded to join the United States in some plan of international bimetallism. Mr McKinley had been heartily in favour of a restoration of free silver, provided it could be brought about safely and honourably; and this view had been very general among leading public men of all parties. At length, however, the Democratic party of the West and South assumed the position that the mints ought to be opened to the free coinage of silver, irrespective of European action, and the Republican party found itself resisting this movement. In the convention at St Louis, 1896, which nominated Mr McKinley for President, the Republicans declared themselves firmly for the existing gold standard until such time as silver might be rehabilitated with the co-operation of leading commercial nations.

The Democratic Convention met a few days later at Chicago, and nominated Mr William J. Bryan for the Presidency, on a platform of the immediate opening of the mints to the free and unlimited coinage of silver at the old ratio with gold of 16 to 1. The Republicans were thus diverted from their expected advocacy of high protection as the principal issue to the defence of the gold standard. The popular vote for McKinley electors in the ensuing election was 7,104,779, and that for Bryan electors about 600,000 less. Mr McKinley received 271 votes in the Electoral College, and Mr Bryan 176.

Immediately after his inauguration on 4th March 1897, President McKinley issued a proclamation calling Congress to assemble in an extra session on 15th March. The Democratic tariff in 1893 had been enacted as part of the general revenue measure which included an income-tax. The income-tax having been declared unconstitutional by the Supreme Court, the measure had failed to produce a sufficient revenue, in consequence of which Mr McKinley's predecessor had been obliged to increase the public debt. Mr McKinley's message to the new Congress dwelt upon the necessity of an immediate revision of the tariff and revenue system of the country, and the so-called Dingley Tariff Bill was accordingly passed through both houses, and was approved by the President on 24th July.

The regular session of Congress which opened in December was occupied with the situation in Cuba. A formidable rebellion of the Cuban patriots against the Spanish Government had begun in 1895, and the unavailing attempts of Spain to subdue it had been upon a large military scale, accompanied by measures of harshness towards the entire population, women and children included, that were resulting in wholesale starvation. A popular demand had arisen throughout the United States for intervention. The already strained situation was rendered worse by an explosion on 15th February 1898, in the harbour of Havana, which resulted in the destruction with great loss of life of the United States battleship *Maine*. The increasing difficulties of the situation led early in March to the unanimous vote in both Houses of Congress of \$50,000,000, to be placed at the disposal of the President, and to be used at his discretion for the national defence. On 23rd March an ultimatum was presented to the Spanish Government by direction of President McKinley, setting forth the intolerable condition that existed in Cuba, and calling upon Spain to relinquish its sovereignty and withdraw from the island. A period of negotiation followed which culminated in Mr McKinley's message to Congress of 25th April recommending a declaration of war against Spain. Such a declaration was immediately passed by both Houses of Congress and approved by the President.

As commander-in-chief of the army and navy of the United States, Mr McKinley prosecuted a brief but vigorous war in which a volunteer army of nearly a quarter of a million men was called into existence, and two Spanish fleets were destroyed—one by the Asiatic squadron under Admiral Dewey in Manila Harbour, the other by the North Atlantic squadron under Admiral Sampson near the harbour of Santiago de Cuba. These victories at sea, together with the surrender to an American expeditionary force of the city of Santiago, in eastern Cuba, led to the signing of a peace protocol on 12th August, which was followed by the signature at Paris on 10th December of articles of peace. After a long discussion the peace treaty was ratified by the United States Senate, 6th February 1899; and in accordance with its terms Porto Rico, the Philippine Archipelago, and a portion of the Ladrone Islands were transferred

by Spain to the sovereignty of the United States, while Cuba came under American jurisdiction pending the establishment there of an independent government. Two days before the ratification of the peace treaty, a conflict took place between armed Filipinos under the leadership of Emilio Aguinaldo and the American forces that were in possession of Manila. The six months that had elapsed between the signing of the peace protocol and the ratification of the treaty had constituted a period of virtual interregnum, Spain's authority having been practically destroyed in the Philippines and that of the United States not having begun. In this period a formidable native Filipino army had been organized and a provisional government created. The warfare waged by these Filipinos against the United States, while having for the most part a desultory and guerilla character, was of a very protracted and difficult nature. Sovereignty over the Filipinos having been accepted by virtue of the ratification of the Paris treaty, President McKinley was not at liberty to do otherwise than assert the authority of the United States and use every endeavour to suppress the insurrection. There was, however, a wide difference of opinion in the United States whether or not it had been wise to accept responsibility for so distant a territorial possession. In the foreign relations of the United States, as directed by President McKinley, the most significant change was the cordial understanding established with the British Government. Under no previous American administration since the establishment of Independence had the relations between the two Governments been so free from difficulty or embarrassment.

The elements which had supported Mr Bryan in 1896 had not been disheartened by their defeat, but had immediately organized for a new campaign in 1900 under the same candidate and with the same platform. The Democratic Convention, held on 4th July at Kansas City, again nominated Mr Bryan and again declared for the free coinage of silver. But the Republican policy of "imperialism" was declared to be "the paramount issue," and Mr Bryan, during a campaign of incessant travel and public speech, constantly denounced the course that had been pursued under Mr McKinley's leadership. The latter was unanimously renominated by the National Republican Convention which met in Philadelphia on 19th June. In 1896 Garret A. Hobart, of New Jersey, had been elected Vice-President, but had died in 1899. At the Philadelphia Convention of 1900, Governor Theodore Roosevelt, of the State of New York, was nominated for the Vice-Presidency. The Republican Convention demanded the maintenance of the gold standard, and pointed to the fulfilment of some of the most important of the pledges given by the Republican party four years earlier. The intervening period had been one of very exceptional prosperity in the United States, foreign commerce having reached an unprecedented volume, and agriculture and manufactures having made greater advancement than in any previous period of the country's history. The tendency towards the concentration of capital in great industrial corporations had been active to an extent undreamt of, with incidental consequences that had aroused much apprehension; and the Democrats accused President McKinley and the Republican party of having fostered the "trusts." As the result of the polling in November, 292 Republican Presidential electors were chosen, while 155 Democratic electors, chiefly in the Southern States, represented the final strength of the Bryan and Stevenson ticket. The Republican popular vote was about 7,208,000, and the Democratic about 6,358,000. Since the re-election of Mr Lincoln in 1864, and of General Grant in 1872, no American President had succeeded in securing a second consecutive term

until Mr McKinley's re-election for the first quadrennial period of the 20th century.

In the term of Congress immediately following the Presidential election it was found possible to reduce materially the war taxes which had been levied on the outbreak of the Spanish-American war. Arrangements were perfected for the termination of the American military occupation of Cuba and the inauguration of a Cuban Republic as a virtual protectorate of the United States, the American Government having arranged with the Cuban Constitutional Convention for the retention of a series of naval stations on the Cuban coast. In the Philippines advanced steps had been taken in the substitution of civil government for military occupation, and a governor-general had been appointed and sent to Manila. Progress had been made towards the final solution of the preliminary problems affecting the construction of a ship canal across the isthmus connecting North and South America, a very important commission of engineers appointed by Mr McKinley having completed its investigations, while negotiations with Great Britain had resulted in a new convention setting aside the Clayton-Bulwer treaty and providing for a canal under American control. Prosperity at home was great, and foreign relations were free from complications. The problems which had devolved upon Mr McKinley's Administration had been far advanced towards final settlement. He retained without change the cabinet of his first Administration. After an arduous and anxious term, which had included the war with Spain, the war against the Philippine insurgents, and participation in the joint expedition to Peking, Mr McKinley had reached a period that promised to give him comparative repose and freedom from care. He had secured, through the co-operation of Congress, the permanent reorganization of the army and a very considerable development of the navy. The public revenues were superabundant, and the nation's outlook had never been so full of promise for peace and general progress. In these circumstances, in accordance with a long-anticipated plan, President McKinley, accompanied by the greater part of his cabinet, set forth in the early summer on a tour to visit the Pacific coast, where he was to witness the launching of the battleship *Ohio* at San Francisco. The route chosen was through the Southern States, where many stops were made, and where Mr McKinley delivered brief addresses. The heartiness of the welcome accorded him seemed to mark the disappearance of the last vestige of sectional feeling that had survived the Civil War, in which Mr McKinley had participated as a young man. After his return he spent the happiest and most restful month of his long period of official life in a visit at his old home in Canton, Ohio. At the end of this visit, by previous arrangement, he visited the city of Buffalo, New York, in order to attend the Pan-American Exposition and make a public address. This address, which was delivered on 5th September 1901, was a public utterance designed by Mr McKinley to affect American opinion and public policy. It declared that henceforth the progress of the nations must be through harmony and co-operation, in view of the fast-changing conditions of communication and trade, and it maintained that the time had come for wide-reaching modifications in the tariff policy of the United States, the method preferred by Mr McKinley being that of commercial reciprocity arrangements with various nations. On the following day, 6th September 1901, a public reception was held for President McKinley in one of the buildings of the Exposition, all sorts and conditions of men being welcome. Advantage of this opportunity was taken by a young man of Polish parentage, by name Leon Czolgosz, to shoot at the President with a revolver at close range. One of the two

bullets fired penetrated the abdomen. After the world had been assured that the patient was doing well and would recover, he collapsed and died on the 14th. The assassin, who professed to hold the views of that branch of Anarchists who believe in the assassination of rulers and persons exercising political authority, was promptly seized, and was subsequently convicted and executed. Mr McKinley's conduct and utterances in his last days revealed a loftiness of personal character that everywhere elicited admiration and praise. Immediately after his death Vice-President Roosevelt took the oath of office, announcing that it would be his purpose to continue Mr McKinley's policy, while also retaining the cabinet and the principal officers of the Government. Mr McKinley's funeral took place at Canton, Ohio, on 19th September, the occasion being remarkable for the public manifestations of mourning, not only in the United States, but in Great Britain and other countries.

(A. SW.)

M'Kinney, a city in the north-east of Texas, U.S.A., capital of Collin county, at the intersection of the Houston and Texas Central, and the Sherman, Shreveport, and Southern railways. It is in a cotton-growing region, and is a compressing and shipping point for that staple. Population (1880), 1479; (1890), 2489; (1900), 4342—50 foreign-born and 917 negroes.

Macleod, Henry Dunning (1821–1902), Scottish political economist, was born in Edinburgh in 1821, and educated at Eton, Edinburgh University, and Trinity College, Cambridge, where he graduated in 1843. He travelled in Europe, and in 1849 was called to the English bar. He was employed in Scotland on the work of poor-law reform, and devoted himself to the study of economics. In 1856 he published his *Theory and Practice of Banking*, in 1858 *Elements of Political Economy*, and in 1859 a *Dictionary of Political Economy*. In 1873 appeared his *Principles of Economist Philosophy*, and other books on economics and banking were published later. Between 1868 and 1870 he was employed by the Government in digesting and codifying the law of bills of exchange. Macleod's principal contribution to the study of economics consists in his work on the theory of credit, to which he was the first to give due prominence. For a judicious discussion of the value of Macleod's writings, see an article on "The Revolt against Orthodox Economics" in the *Quarterly Review* for October 1901 (No. 388). He died on 16th July 1902.

MacMahon, Marie Edmé Patrice Maurice de, DUC DE MAGENTA (1808–1893), French Marshal and President of the Republic, was born on 13th July 1808 at the château of Sully, near Autun. He was a descendant of an Irish family who went into exile with James II. Educated at the military school of St Cyr, in 1827 he entered the army, and soon saw active service in the French campaign in Algeria, where his ability and bravery became conspicuous. He was in the engagement at the Col de Terchia, and was subsequently sent on a difficult and dangerous mission to the general in command at Blida. This he successfully accomplished. Being recalled to France, he gained renewed distinction in the expedition to Antwerp in 1832. He became captain in 1833, and in that year returned to Algeria. He led daring cavalry charges across plains infested with Bedouin, and especially distinguished himself at the siege of Constantine in 1837. From then until 1855 he was almost constantly in Algeria, and rose to the rank of general of division. During the Crimean war MacMahon was given the command of a division, and in September 1855 he successfully conducted the assault upon the Malakoff redoubt which led to the fall of Sebastopol. After his return to France honours

were showered upon him, and he was made a senator. Desiring a more active life, however, and declining the highest command in France, he was once more sent out, at his own request, to Algeria, where he completely defeated the Kabyles. After his return to France he voted as a senator against the unconstitutional law for general safety, which was brought forward in consequence of Orsini's abortive attempt on the emperor's life. MacMahon greatly distinguished himself in the Italian campaign of 1859. Partly by good luck and partly by his boldness and sagacity in pushing forward without orders at a critical moment at the battle of Magenta, he enabled the French to secure the victory. For his brilliant services MacMahon received his marshal's baton and was created duc de Magenta. In 1861 he represented France at the coronation of William I. of Prussia, and in 1864 he was nominated governor-general of Algeria. MacMahon's action in this capacity formed the least successful episode of his career. Although he did institute some reforms in the colonies, complaints were so numerous that twice in the early part of 1870 he sent in his resignation to the emperor. When the ill-fated Ollivier Cabinet was formed the emperor abandoned his Algerian schemes, and MacMahon was recalled.

War being declared between France and Prussia in July 1870, MacMahon was appointed to the command of the First Army Corps, his mission being to defend Alsace. On 6th August MacMahon was in chief command at Woerth, having under him a total of 50,000 men, and he occupied a strong position on the slopes of the Vosges. The Germans numbered about 120,000 men. The Marshal fought valiantly, and his courage in braving death again and again extracted the admiration even of his foes. But all was in vain, and the superior strength and strategy of the Germans triumphed. MacMahon was compelled to retreat upon Nancy, leaving in the enemy's hands 4000 prisoners, 36 cannon, and 2 standards. He fell back upon Saverne, and from thence proceeded in succession to Toul, Rheims, and Reithel. Though he suffered further losses in the course of his retreat, his movements were so ably conducted that the emperor confided to him the supreme command of the new levies which he was mustering at Châlons, and he was directed to effect a junction with Bazaine. This operation he undertook against his will. He had an army of 120,000 men with 324 guns; but large numbers of the troops were disorganized and almost entirely without discipline. On 25th August the Germans ascertained that MacMahon was endeavouring to effect a union with Bazaine at Metz, and altered their plans in order to circumvent him. When the Marshal reached Sedan with his dispirited troops, it was only to find that he was surrounded by the enemy, who by vigorous forward movements had captured the bridges over the Meuse and the commanding positions round the town. Early on 1st September the fierce and decisive battle of Sedan began. After some hours of sanguinary fighting MacMahon was dangerously wounded in the thigh, and resigned his command to General Wimpffen, who soon found he had no choice but to surrender. MacMahon shared the captivity of his comrades in Germany, and resided at Wiesbaden until the conclusion of peace.

In March 1871 the Marshal was appointed by Thiers commander-in-chief of the army of Versailles; and in that capacity he suppressed the Communist insurrection, and successfully conducted the second siege of Paris. In the following December the Marshal was invited to become a candidate for Paris in the elections to the National Assembly, but declined nomination. On the resignation of M. Thiers as President of the Republic, on 24th May 1873, MacMahon was elected to the vacant

office by an almost unanimous vote, being supported by 390 members out of 392. The Marshal accepted the Presidency in a manly and dignified letter. The duc de Broglie was empowered to form a Conservative administration, but the President also took an early opportunity of showing that he intended to uphold the sovereignty of the National Assembly. On 5th November 1873 General Changarnier presented a motion in the Assembly to confirm MacMahon's powers for a period of ten years, and to provide for a commission of thirty to draw up a form of constitutional law. The Marshal consented, but in a message to the Assembly he declared in favour of a confirmation of his own powers for seven years, and expressed his determination to use all his influence in the maintenance of Conservative principles. After prolonged debates the Septennate was adopted on 19th November by 378 votes to 310. There was no *coup d'état* in favour of "Henri V.," as had been expected, and the President resolved to abide by "existing institutions." One of his earliest acts was to receive the finding of the court-martial upon his old comrade in arms, Marshal Bazaine, whose death sentence he commuted to one of twenty years' imprisonment in a fortress. Though MacMahon's life as President of the Republic was of the simplest possible character, his term of office was marked by many brilliant displays, while his wife was a leader in all works of charity and benevolence.

The President was very popular in the rural districts of France, through which he made a successful tour shortly after the declaration of the Septennate. But in Paris and other large cities his policy soon caused great dissatisfaction, the Republican party especially being alienated by press prosecutions and the attempted suppression of Republican ideas. Matters were at a comparative deadlock in the National Assembly, until the accession of some Orleanists to the Moderate Republican party in 1875 made it possible to pass various constitutional laws. In May 1877, however, the constitutional crisis became once more acute. A peremptory letter of censure from MacMahon to Jules Simon caused the latter to resign with his colleagues. The duc de Broglie formed a ministry, but Gambetta carried a resolution in the Chamber of Deputies in favour of parliamentary government. The President declined to yield, and being supported by the Senate, he dissolved the chamber, by decree, on 25th June. The prosecution of Gambetta followed for a speech at Lille, in which he had said "the Marshal must, if the elections be against him, *se soumettre ou se démettre*." In a manifesto respecting the elections, the President referred to his successful government, and observed, "I cannot obey the injunctions of the demagogy; I can neither become the instrument of Radicalism nor abandon the post in which the constitution has placed me." The confidence of the Marshal in the result of the elections was misplaced. Notwithstanding the great pressure put upon the constituencies by the Government the elections in October resulted in the return of 335 Republicans and only 198 anti-Republicans, the latter including 30 MacMahonists, 89 Bonapartists, 41 Legitimists, and 38 Orleanists. The President endeavoured to ignore the significance of the elections, and continued his reactionary policy. As a last resort he called to power an extra-parliamentary cabinet under General Rochebouet, but the Republican majority refused to vote Supplies, and after a brief interval the President was compelled to yield, and to accept a new Republican ministry under M. Dufaure. The prolonged crisis terminated on 14th December 1877, and no further constitutional difficulties arose in 1878. But as the senatorial elections, held early in 1879, gave the Republicans an effective working majority in the Upper

Chamber, they now called for the removal of the most conspicuous anti-Republicans among the generals and officials. The Marshal refused to supersede them, and declined to sanction the law brought in with this object. Perceiving further resistance to be useless, however, the Marshal resigned the Presidency on 30th January 1879, and M. Jules Grévy was elected as his successor.

Marshal MacMahon now retired into private life, having already passed his seventieth year. Relieved from the cares of state, his simple and unostentatious mode of existence enabled him to pass many years of dignified repose. He died at Paris on 17th October 1893, in his eighty-sixth year. A fine, tall, soldierly man, of a thoroughly Irish type, in private life the Marshal was universally esteemed as generous and honourable; as a soldier he was brave and able, without decided military genius; as a politician he was patriotic and well-intentioned, but devoid of any real capacity for statecraft.

(G. B. S.)

Macomb, a city of Illinois, U.S.A., capital of McDonough county, on the Chicago, Burlington, and Quincy railway, in the western part of the state. Population (1890), 4053; (1900), 5375.

Macon, a city of Georgia, U.S.A., capital of Bibb county, on the Ocmulgee river, at the head of navigation, in the central part of the state, at an altitude of 334 feet. It is the intersecting point of six railways, which make it, after Atlanta, the most important railway junction of the state. It is situated in the cotton belt, and has a large cotton trade. In 1900 its manufacturing establishments numbered 182, with a capital of \$5,076,005, and products valued at \$6,495,767. They employed an average number of 3700 wage-earners, who received \$1,047,437 total wages. The principal article of manufacture (rapidly growing) was cotton goods, the product of which was valued at \$1,237,125. Other products of importance are railway cars, lumber, and foundry and machine-shop products. Macon is the seat of a number of educational institutions, among which are Mercer University, which in 1899 had 15 instructors and 252 students, and Wesleyan Female College, with 20 instructors and 185 students. The assessed valuation of real and personal property in 1899 was \$14,023,942, the net debt of the city was \$752,193, and the rate of taxation was \$26.50 per \$1000. Population (1890), 22,746; (1900), 23,272, of whom 478 were foreign-born and 11,550—almost one-half of the total—were negroes.

Macquarie, a British island in the South Pacific, about 500 miles south-west of New Zealand, in 54° 30' S. and 158° 50' E. It is about 20 miles long, and covered with a grassy vegetation, with some trees or shrubs in the sheltered places which afford food to a parrot of the genus *Cyanorhamphus*, allied to those of the Auckland Islands. Although it has no settled population, Macquarie is constantly visited by sailors in quest of the seals which abound in its waters.

Madách, Imre (1829–1864), Hungarian dramatist, was born at Alsó-Sztrégova in 1829. He took part in the great revolution of 1848–49, was imprisoned, and on his return to his small estate in the county of Nógrád, he found that his family life had meanwhile been completely wrecked. This only increased his natural tendency to melancholy, and he withdrew from public life till 1861, devoting his time mainly to the composition of his great work, *Az ember tragédiája* (*The Tragedy of Man*). John Arany, then at the height of his fame as a poet, at once recognized the great merits of that peculiar drama, and Madách enjoyed a short spell of fame before his untimely death of heart disease in 1864. In *The Tragedy of Man* Madách takes us from the hour when Adam and Eve

were innocently walking in the Garden of Eden, to the times of the Pharaohs; then to the Athens of Miltiades; to sinking Rome; to the period of the Crusaders; into the study of the astronomer Kepler; thence into the horrors of the French Revolution; into greed-eaten and commerce-ridden modern London; nay, into the ultra-Socialist state of the future, when all the former ideals of man will by scientific formulæ be shown up in their hollowness; still further, the poet shows the future of ice-clad earth, when man will be reduced to a degraded brute dragging on the misery of his existence in a cave. In all these scenes, or rather anticipatory dreams, Adam, Eve, and the arch-fiend Lucifer are the chief and constantly recurring *personæ dramatis*. So, in the end, Adam, despairing of his race, wants to commit suicide, when in the critical moment Eve tells him that she is going to be a mother by him. Adam then prostrates himself before God, who encourages him to hope and trust. The diction of the drama is elevated and pure, and although not meant for the stage, it has proved very effective at several public performances. Concerning Madách there is an ample literature, consisting mostly of elaborate articles by Charles Szász (1862), Augustus Greguss (1872), B. Alexander (1871), M. Palágyi (1890), and others.

(E. RE*.)

Madagascar, an important island in the Indian Ocean, and the third largest island in the world, about 300 miles from the south-east coast of Africa. It is 985 miles in length from north to south, and about 250 miles in average breadth, although near the centre it is nearly 350 miles across; its area is about 230,000 square miles. In 1902 the governor, General Gallieni, proposed to remove the capital from Antananarivo in the interior to Tamatave on the east coast. Since the French conquest of Madagascar in 1895 great advances have been made in the triangulation, surveying, and mapping of the interior; and although detailed surveys have still to be made of the greater portion, the country has been traversed in many directions by French military officers and other travellers; and the provinces of Imèrina and Bètsiléô, as well as several of the chief river valleys, have been mapped very minutely. The south-western corner of the island is now the only large portion still unexplored.

The geology is far from being completely known, but much has been done towards the examination of the rocks of the interior northern provinces, as well as of those of the coast. **Geology.** plains of the northern half. A considerable collection of fossils has been made, and a large number of rock sections prepared for polariscopic investigation. From the information thus obtained it may be affirmed that "by far the greater part of the north-eastern half of Madagascar consists of gneiss and other crystalline rocks, although gneiss very largely predominates. Granite occurs frequently in the form of bosses, and in some places apparently intercalated with the crystalline schists. Diorite is also frequently met with, but gneiss is certainly the prevailing rock." "The region occupied by these crystalline (chiefly metamorphic) rocks has a length of about 730 miles, and an average breadth of probably not less than 150," with a total area of 100,000 or possibly 130,000 square miles. "Among the accessory minerals existing in the gneiss are magnetite, iron-pyrites, clay slate, hornblende, actinolite, mica-, chlorite-, and cyanite-schists, crystalline limestone, quartzite, graphite, and many varieties of quartz. Granite forms some of the most remarkable of the mountains and hill ranges of the interior."¹ Vast portions of the country are covered by red soil, which resembles and is often described as clay, but is really decomposed rock, chiefly gneiss, reddened with oxidized magnetite. The lower portions of Madagascar, chiefly situated in the west and south, which do not apparently much exceed 600 feet in height above the sea-level, consist of sedimentary rocks, the fossils of which show that they belong to the Jurassic, Cretaceous, and Eocene systems. In the north-west of the island sandstone covers a vast extent of country, beds of clay and shale are common,

¹ The above extracts are from a paper by the Rev. R. Baron, F.G.S., in *Quart. Jour. Geol. Soc.*, May 1889; to him we owe most of our knowledge of the geology as well as of the botany of Madagascar.

and there are extensive deposits of limestone. Lignite has been discovered in the same part of the island, but hitherto no true coal has been found. As regards metals, gold has been worked in many parts of the central and north-western regions, but not in large quantities in any one place. Lead is obtained from galena, and nickel and copper are also found in certain localities. Iron is found in abundance as magnetite, also as hæmatite and ironstone. Sulphur, saltpetre, bitumen, and lime are also procured, the last-named from the travertine springs of Antslrabè; while corundum, sapphires, spinel, rutile, and tourmaline are among the more precious products. In addition to the Secondary and Tertiary strata already mentioned, there are also beds of a much more modern date (Quaternary), containing fossils of recently extinct birds, mammals, and reptiles (see section on Palæontology).

Observations have shown that the yearly rainfall of the interior averages about 53 inches, while that of the east coast is about 95 inches. On the north-west coast the rainfall is slightly in excess of that of the interior.

About 4100 flowering plants, of which a large proportion (about three-fourths) is endemic, are now known to botanists. The forest

Flora. belt which extends round the island is densest on the eastern side, where it averages 30 miles in width, but on the north-east it attains a breadth of 50 to 60 miles; it is from 1500 to 1600 miles long. On the western side the woods are thinner and more scattered. It is estimated that there are probably 35,000 square miles of forest-covered country in Madagascar, or about one-seventh of its whole surface. The hard-wooded and valuable timber trees contained in these forests include various species of *Weinmannia* (*Lalôna*),¹ *Elaeocarpus* (*Voânana*), *Dalbergia* (*Voambôana*), *Nuxia* (*Vâlanirana*), *Podocarpus*, a pine, the sole species in the island (*Hêtatra*), *Tambourissa* (*Ambôra*), *Neobaronia* (*Hârahâra*), *Ocotia* (*Varôngy*), and probably ebony, species of *Diospyros*, &c. Then, besides those species described in the ninth edition of this work on account of their peculiar characteristics, the tall fir-like *Casuarina equisetifolia*, or beef-wood tree, is very prominent on the eastern coast, as well as several species of screw-pine (*Pandanus*). On the western coast dense thickets of mangrove line the shores of all creeks and rivers, and on all the coast lagoons and lower reaches of the rivers the *Viha* (*Typhonodorum lindleyanum*), a gigantic arum endemic to Madagascar, grows in great profusion to a height of 14 or 15 feet, and has a large white spathe of more than a foot in length. About 70 additional species of ferns have been discovered, making the total number as yet collected some 320. Two of the several beautiful orchids found strike the attention of every traveller on the east coast during the months of June and July by their abundance. One of these, *Angraecum superbum*, has a number of spikes of pure white flowers; the other, *A sesquipedale*, has larger but fewer flowers and has a remarkably long spur. The Rev. R. Baron, F.L.S., divides the flora into three distinctly-marked "regions." These run in a longitudinal direction, following approximately the longer axis of the island, and are termed respectively eastern, central, and western. Of these, the central includes the elevated plateaux of the interior, while the eastern and western occupy the two sides of the island, including the forest belts and most of the wooded country. The divisions between the eastern and western regions in the extreme north and south are almost arbitrary, and cannot be defined with much accuracy. The flora of the extreme south-west is least known, but appears to be marked by numerous spiny plants adapted to its very dry climate. Of the 4100 known plants composing the Madagascar flora, there are Dicotyledons, 3492; Monocotyledons, 248; Acotyledons, 360. Of these, the orders most largely represented (together with their species) are Leguminosæ, 346; Filices, 318; Compositæ, 281; Euphorbiacæ, 228; Orchidæ, 170; Cyperacæ, 160; Rubiacæ, 147; Acanthacæ, 131; Gramineæ, 130. The number of endemic genera now known is 148. Of the 3178 species of plants whose localities have been determined, 35 per cent. are peculiar to the eastern region, 27.5 per cent. to the central, and 22 per cent. to the western. One natural order, *Chlænacæ*, is strictly confined to Madagascar.

Fauna.—Thirty-nine species of *Lemuroida* are now known to exist in the island, while more than 260 species of birds have been classified. Madagascar may also be considered one of the headquarters of the *Chamelionide*, for of the 50 known species no fewer than 25, or half of them, have already been described from the island. Many of these are of curious form, with remarkable developments of the plates of the head and projecting horns and spines.

Closely connected in interest with the animal life at present found in Madagascar is that of the extinct fauna. Researches in various parts of the island have revealed the existence in quite recent deposits, in a sub-fossil state, of the bones of numerous birds of the family *Struthidæ*. These have been arranged in twelve species, belonging to two genera, *Epyornis* and *Mullerornis*, and vary in size from that of a bustard

to that of birds much exceeding an ostrich, and rivalling the recently extinct Moa of New Zealand, one or two species being about 10 feet high. One species of these great wingless birds laid an egg which is the largest known, being 12½ inches by 9½ inches. Associated with these remains are found those of a large rail and a wild-goose, but much larger than any now inhabiting Madagascar. In the same beds the remains of probably three extinct species of hippopotamus have been found, about two-thirds the size of the living African species; also the bones and carapace, &c., of gigantic tortoises, the bones of a species of swine, as well as of a river-hog, and also of a slender-legged form of zebu-ox. Near the south-west coast the skull of a large extinct lemuroid animal has been discovered by Mr J. T. Last, much longer in shape than that of any living lemur, the animal being probably three times the size of any known lemuroid. Most, if not all, of the above-mentioned birds and animals were probably contemporaneous with the earliest human inhabitants of Madagascar. The remains of an animal which appears to form a link between the apes and the lemurs have been discovered; and in 1899 the bones of another gigantic lemuroid, much larger than that just mentioned, were found by M. A. Grandidier.² In the deposits of a much more remote era than those already spoken of—the Jurassic—the bones of some enormous terrestrial lizards have been found by Mr Last, belonging to two if not three species; these are described as belonging to a Sauropodous Dinosaur of the genus *Bothriospondylus*. And in the beds of the Lower Oolite the Rev. R. Baron had previously discovered fragments of the skull of a reptile resembling the gavial of the Ganges; from these a new genus has been founded by Mr R. B. Newton, which he calls *Steneosaurus*. The mammals, birds, and reptiles here described—twenty-six or twenty-seven in number—comprise all that is at present known of the ancient vertebrate fauna of Madagascar. A complete list of all the fossils of the island then known is given by Mr Newton in *Quar. Jour. Geol. Soc.*, February 1895. These, omitting the vertebrates already described, number 140, and belong to the Mollusca, Foraminifera, Echinodermata, Actinozoa, and Plantæ.

History.—The year 1882 was important as marking the beginning of a great change in the history of the island. Towards the middle of the year the relations between the native government and that of France became much strained, and many complaints were made by the latter against the Malagasy, together with demands for compensation. In order to settle, if possible, these causes of dispute, two Hova officers of high rank were sent to France as ambassadors, but as they were not authorized to concede any territory, their visit accomplished very little. They subsequently concluded treaties with Great Britain, Germany, and America, giving improved facilities for trade with Madagascar, but before their return matters had come to a crisis in the island. In May 1883 an ultimatum was sent to the Malagasy queen, requiring immediate compliance with the demands of France; and as these were refused by the Hova Government, the town and defences of Tamatave were bombarded by a French squadron and were then occupied by the marines, the Malagasy soldiers retiring. Several of the other ports were bombarded from time to time, and the war continued in a desultory fashion for many months; but no serious attempt was made to invade the interior; and at length, in 1885, terms of peace were agreed to. By a treaty signed on 12th December it was agreed that the foreign relations of Madagascar should be directed by France; that a Resident should live at the capital, with a small guard of French soldiers; and that the Bay of Diego Suarez, together with surrounding territory, should be ceded to France. These were the most important provisions, but the word "protectorate" was carefully excluded from the wording of the treaty, although doubtless the French envoys intended that this should be its practical issue. It was at the same time agreed that there should be no foreign interference with the internal government of the country, and that the queen should retain her former position, with all its honours and dignity.

Franco-Malagasy war of 1883-85.

² "Nombreux ossements de lémuiriens disparus, dont la taille était énorme, plus grande que celle d'un homme."—*La Géographie*, January 1900, p. 80.

¹ The words in parentheses are the native Malagasy names.

For about nine years this treaty continued in force: several French Residents successively represented France at Antananarivo; but these found themselves quite unable to obtain that influence in the country which the home authorities thought they had a right to demand. The Malagasy prime minister was not disposed to give any advantage to France beyond what he could help, and at the same time he continued to arm and train, by the help of British officers, a large body of native soldiers. It was inevitable that this state of tension and irritation could not last, and at length, towards the close of 1894, the French Government sent an ultimatum to the Malagasy sovereign, with the following demands: (1) The Malagasy Government to have no dealings with other Powers except through the Resident-General. (2) All concessions to be void unless approved and registered by the Resident-General. (3) The French Government to have power to place soldiers in Madagascar as it may consider necessary. (4) The French Government to have power to carry out works of public utility. (5) French text of treaties alone to be authoritative. These demands were refused by the native Government, and other conditions were offered; but the French envoy, together with the Resident's escort, left the capital, as also did the French traders and others,

French invasion and conquest, 1895.

as all these had left the island, the chief ports were occupied by French troops, and an expeditionary force under General Duchesne was afterwards landed on the north-west coast at Mojangà, with the object of advancing into the interior and breaking the Hova authority. Owing to the necessity of making a road for the passage of artillery and military stores, many months were spent on the way in the early part of 1895, and there was considerable loss of life by fever and other disease among the invading troops. But no effectual resistance was made by the Malagasy, and at length, on the 30th September, the French forces appeared on the heights to the north and east of Antananarivo, bombarded the city, which surrendered in the afternoon, and on the evening of the same day the French entered the capital.

The result of this event was that the protectorate of France was re-established in the central provinces, but the queen was still allowed to retain her position. In the early part of the following year (1896), however, a serious rebellion broke out in several parts of Imèrina, and soon gained ground. This movement was not only anti-French and anti-foreign, but also distinctly anti-Christian. The French troops gradually broke up the power of the rebellion in the central provinces, but as there appeared to be considerable unrest in many other parts of the island, General Gallieni, an officer with a reputation for vigour and ability in the Sudan and Tongking campaigns, was sent out to relieve the then Resident-General.

General Gallieni had a difficult task before him in establishing the authority of France throughout the island among numbers of tribes who had never submitted to any control from others. Among the first steps he took were to put the country under martial law, to abolish royalty and all semblance of Hova government, and to declare Madagascar to be henceforth a colony of France. Queen Ranavàlona III. was exiled to Réunion, and subsequently to Algeria. Meanwhile carriage roads were commenced to connect all the chief centres, and the military posts were gradually extended farther and farther from the central provinces, so as effectually to put down all opposition and to consolidate French rule over all the outlying tribes. French Residents and numerous other officials were placed at every

important town, and various projects were started for the civilization of the Malagasy in accordance with French ideas. The area of the disturbed and unsettled parts of the country was lessened month by month, until, at the close of 1899, General Gallieni was able to report that only portions of the west and south-west remained to be brought into submission. In January 1899 three-fourths of the island was still under military administration. According to the French budget of 1900, the troops in Madagascar amounted to 11,305, of whom 7500 were natives. Diego Suarez, at the northern extremity of Madagascar, held as a French colony from 1885, was in 1896 placed under the authority of the Governor-General.

In the absence of any census, or registration of births, deaths, and marriages, it is impossible to give accurate statistics as to the movement of population; and trustworthy figures of commerce, &c., are likewise very difficult to obtain. It is believed that the population of the whole of Madagascar does not exceed 3,000,000, of whom probably nearly one-third inhabit Imèrina. Antananarivo contains 60,000 people, but the number is very variable.

General condition of the country; statistics.

Notwithstanding repeated proclamations assuring the people that perfect religious liberty was guaranteed by France, the Jesuit missions have made strenuous efforts to break up the numerous Protestant village churches. The French Protestant churches, too, began to take part in 1896 in the missionary work carried on in the new colony, and nearly half the area for long occupied by the London Missionary Society has been transferred to the Paris Society. The bulk of the Malagasy converts are still Protestants, *i.e.*, some three-fourths, probably, of the 150,000 people confessing Christianity. Since 1897 high schools, medical and technical schools, and a few primary schools have been formed by the Government, but the bulk of the educational work is still carried on by the various missionary societies. The Jesuit mission is making strenuous efforts to control education, but the Protestant missions are not less strenuous in maintaining and adding to their primary and high schools and colleges. No statistics can be given as to education, but it is probable that 100,000 children are now being instructed. Information about the people, their language, and their civilization has become fuller, but nothing has been discovered materially to modify the conclusions formerly arrived at. With regard to "ranks of society," slavery was abolished by the French in 1896, and by this act the third great class of the *andèvo* or slaves has become merged in the second, that of the Hova or commoners. The division between the Andriana or nobles and the Hova remains unaltered, notwithstanding that royalty has been abolished. In the other tribes chieftainship is still retained in the administration of the country under the surveillance of French officials. The local budget for 1897 was 4,269,000 francs (about £178,000), which practically covered the expenditure apart from the cost of civil and military administration, for which a sum of 15,170,000 fr. (about £632,000) was voted by the French Chambers; in 1898 these sums were respectively 9,437,000 fr. (£393,000) and 20,185,000 fr. (£841,000). In 1899 the estimated revenue was 11,136,000 fr. (£445,440), including 1,800,000 fr. (£72,000) subvention from France. The cost of Madagascar to France for 1900 was estimated at over 25,000,000 fr. (£1,000,000). The converted debt of Madagascar stood at 20,000,000 fr. (£800,000) at 2½ per cent. in 1900. 1898 many parts of Imèrina suffered severely from famine, which was largely due to the depopulation of large portions of the country by the rebellion of 1896, and the destruction by the rebels of the stores of rice. Agriculture is being encouraged by the formation of *jardins d'essai* near every village; but, on the whole, the agriculture of the Malagasy has been only slightly influenced by political changes, the chief difference being the more extended cultivation of European vegetables and fruits. Their handicrafts have, however, been less exercised, partly through the demands made on the people for Government service (*corvée*), and partly through the greater employment of foreign textile fabrics. The use of sun-dried and of burnt bricks and tiles for all kinds of building has greatly extended, and has much altered the appearance of every town and village in the central provinces. As in all French colonies, very heavy duties are levied upon all imports and exports coming from and going to other countries than France, and this has naturally greatly diminished British as well as American trade with the island, while increasing French imports and exports. The total imports in 1888 were valued at £162,000; in 1898 at £865,640. The United Kingdom's share in the total for 1888 was estimated at £101,000; in that for 1897 at £179,000; for 1898 at £42,000—a great drop. Further, the sum for 1897 included £146,000 for cotton piece goods, an amount which, in consequence of the heavy duties imposed, dwindled to £35,000 in 1898. On the other hand, the figures for

the import of cotton piece goods from France were £19,000 in 1897, but £220,000 in 1898. Imports from the United States were valued at £99,000 in 1896, when those from the United Kingdom totalled £270,000. The total exports in 1888 were valued at £174,000; in 1898 the total was £198,400. Exports to the United Kingdom rose from £43,000 in 1888 to £139,000 in 1895, only to fall again to £62,000 in 1896 and £32,920 in 1898. Exports to France rose from £17,000 in 1895 to £74,680 in 1898. The chief exports are cattle, caoutchouc, and hides. In 1898, 6061 vessels of 879,362 tons entered and cleared the ports, the bulk being French. The carriage roads from the east and north-west to connect the interior with the chief ports are making steady progress, and arrangements are also being made for the construction of railways and canals. There is interior telegraphic communication between Antananarivo and Tamatave and Mojangà, which is now being extended to the Betsilé province. French coin is now the only legal currency, and French weights and measures alone are legal.

French Wars in Madagascar.—In 1882 the French claimed a protectorate over the north-west coast of Madagascar, based on alleged treaties with chiefs of the Sakalava tribes which inhabit that part of the island. Queen Ranavalona II. denied the validity of the claim, and, after fruitless endeavours by the British Government to effect a peaceable settlement, hostilities commenced in 1883. Rear-Admiral Pierre bombarded several coast towns and occupied Mojangà, in the north-west, a port which is the key to the province of Imèrina, and Tamatave, the chief town on the east coast. Ranavalona II. died on 13th July 1883, and was succeeded by her niece, Ranavalona III. Reinforcements having arrived from France and Réunion,

Rear-Admiral Galiber, who had succeeded to the command, after unsuccessful negotiations with the Hova Government, destroyed a number of towns on the eastern seaboard and blockaded others, but was too weak to attempt any inland expedition. An Englishman named Willoughby, who had raised and commanded some irregular horse in the Zulu war, was made first adjutant-general and, later, commander-in-chief of the Malagasy army, which he reorganized. With 10,000 men he occupied a very strong entrenched position at Manjakandrianombana, about five miles from Tamatave. In the meantime, in April 1884, Rear-Admiral Galiber was succeeded by Rear-Admiral Miot, who blockaded the ports, but was defeated in June in an attack in force on Manjakandrianombana. Towards the end of the year Admiral Miot occupied Diego Suarez and adjacent ports after some fighting, and a sharp and successful action at Andraparany on the 5th December placed the whole of the north-east of the island in his hands. His troops, however, suffered so severely from malarial fever that the reinforcements which he received from France, Réunion, and Tongking were only sufficient to make good the "waste." In 1885 Willoughby formed a camp of exercise covering Antananarivo, the capital, and an unsuccessful attempt was made to recapture Mojangà from the French. On 26th August a sharp action was fought at Ambodimadiron, near Passandava Bay, which was claimed as a victory by both sides; Marovoay was bombarded, and on the 10th September an unsuccessful attack was made by the French on the Hova position at Farafette, Admiral Miot personally leading a column. In November negotiations were commenced, which resulted in a treaty of peace, by which Madagascar became politically a French protectorate. The treaty was ratified by the Senate in March 1886, but was not recognized by the British Government until August 1890. In 1893 conflicts between the Hovas and the French led to a partial blockade of the ports by the French in 1894 and, at the end of that year, to an open rupture, followed by the occupation of Tamatave and, in January 1895, by the bombardment and occupation of Mojangà. The French Government then organized an expedition under General of Division Duchesne, consisting of two brigades commanded by Generals of Brigade Metzinger and Voyron, in all some 8400 men. Duchesne arrived at Mojangà in May, and found that Metzinger had already captured Marovoay and Midiani by storm, and that Ambohimarinà had been occupied after severe fighting. Early in June Duchesne crossed the Betsiboka and captured Mevatanana, but experienced such great difficulties from insufficient transport and heavy mortality from sickness amongst his troops that it was not until the 12th August that he arrived near Andriba, which he captured on the 22nd. Here he formed an advanced base and organized a flying column to march on Antananarivo. In command of this column he defeated the Hovas with great loss at Tsinaïndry, and after a sharp action captured Antananarivo, the capital, on the 30th September, when he dictated terms of peace. The campaign, although successful in attaining its object, was a problem in transport and hygiene which cannot be said to have been satisfactorily solved. The so-called "pacification" of Madagascar was very thoroughly carried out after September 1896 by General Gallieni. (R. H. V.)

Madava Rao, Sir Raja T. (1828-1891), native Indian statesman, was born at Combaconum in Madras in 1828. Madava Rao created a new type of minister adapted to the modern requirements of a progressive native state, and he grafted it upon the old stock. He linked the past with the present, using the advantages of heredity, tradition, and conservatism to effect reforms

in the public administration and in Indian society. He attained the position of Diwan of Travancore in 1857, and died on the 4th April 1891. Sprung from a Maratha Brahman stock, the son of a Diwan of Travancore, he was educated in the strictest tenets of his sacred caste. But he readily imbibed the new spirit of the age. To mathematics, science, and astronomy he added a study of English philosophy and international law, and a taste for art and pictures. Although a devout student of the Shastras, he advocated female education and social reform. Refusing to cross the sea and so break caste by appearing before a Parliamentary commission, he yet preached religious toleration. A patron of the Indian Congress, he borrowed from the armoury of British administration every reform which he introduced into the native states. He was respected alike by Europeans and natives, and received titles and honours from the British Government. As tutor of the Maharaja of Travancore, and then as revenue officer in that state, he showed firmness and ability, and became prime minister in 1857. He found the finances disorganized, and trade cramped by monopolies and oppressive duties. He co-operated with the Madras Government in carrying out reforms, and, when his measures led to misunderstandings with the Maharaja, he preferred honourable resignation to retention of a lucrative office in which he was powerless for good. In 1872 he was engaged at Indore in laying down a plan of reform and of public works which he bequeathed to his successor, when a grave crisis at Baroda demanded his talents there. The Gaekwar had been deposed for scandalous misrule, and an entire reorganization was needed. Aided by Sir Philip Melvill, Madava Rao swept away the corrupt officials, privileged sardars, and grasping contractors who had long ruined Baroda. He wrote able minutes defending the rights and privileges of the Gaekwar from fancied encroachment, and justifying the internal reforms which he introduced. He resigned office in 1882, and in his retirement devoted his leisure to reading and writing upon political and social questions. (w. L.-w.)

Madeira, a group of islands in the Atlantic, belonging to Portugal, situated about 500 miles southwest from Lisbon, 3½ days' steaming from Southampton, and 5 days from Liverpool. The capital is Funchal, the seat of a bishop (a suffragan of Lisbon), with 37,011 inhabitants (1900). The district of FUNCHAL, which embraces the entire archipelago, *i.e.*, the islands of Madeira, Porto Santo, the Desertas (Chão, Deserta, Grande, and Bugio), and the two Selvagens, has an area of 315 square miles, and population (1890), 134,040 and (1900) 150,528. There is a medical school at Funchal; also a lyceum. The principal products are wine, sugar, corn, vegetables, potatoes, chestnuts, yams, oranges, honey, walnuts, lemons, wax, olive oil, spirits, bananas, apples, and mangoes. The area planted with vines in 1892 was 24,620 acres, which yielded 867,250 gallons of wine (a fairly average year), valued at £34,000; but since then more land has been replanted with vines. In 1899 the wine exported was valued at £173,333. Sugar, spirits, soap, straw hats, ale, leather, embroidery, baskets, wooden wares, butter, linen, and woollens are manufactured. In 1898 there were 1336 persons engaged in fishing; they used 496 boats, and caught fish to the value of £8100. The total trade increased in value from £428,000 in 1893 to £628,000 in 1900, wine being the principal export, with embroidery, vegetables, fruits, and wicker goods. Between 1860 and 1900 the export of wine increased from 104,880 gallons to 587,880 gallons, the value in the latter year being £137,800. In the year 1899 a total of 1635 vessels of 4,692,264 tons entered and cleared the island ports. There are some 580 miles

of roads in Madeira. The chief island is coming more into repute as a winter station.

Madeira River. See AMAZON.

Madhu Sudan Datta (or MICHAEL MADHU SUDAN DATTA, as he was called after he had embraced the Christian religion) (1824–1873), the greatest poet of India in the 19th century, was born at Sagandari, in the district of Jessor in Bengal, in 1824. His father was a pleader in Calcutta, and young Madhu Sudan received his education in the Hindu College of Calcutta, and was the foremost among the distinguished young students of his day, many of whom lived to make their mark in the literature and social progress of their country. Madhu Sudan left the college in 1842, and in the following year ran away from his father to avoid a marriage to which his father wished to force him, and embraced the Christian religion. Continuing his study now in the Bishop's College, Madhu Sudan learnt Greek and Latin and some modern European languages, and in 1848 went to Madras. There he wrote English verses, and married the daughter of a European indigo-planter, but was soon separated from her. He then united himself with an English lady, the daughter of an educational officer; and she remained true to him through life amidst all his misfortunes, and was the mother of the children he left. Madhu Sudan returned to Calcutta with his English wife in 1856, and soon discovered that the true way for winning literary fame and distinction was by writing in his own language, not by composing verses in English. His three classical dramas—*Sarmishtha*, *Padmavati*, and *Krishna Kumari*—appeared between 1858 and 1861, and were recognized as works of merit. But his great ambition was to introduce blank verse into Bengali. His knowledge of Sanskrit poetry, his appreciation of the Greek and Latin epics, and his admiration of Dante and of Milton, impelled him to break through the fetters of the Bengali rhyme, and to attempt a spirited and elevated style in blank verse. His first poem in blank verse, the *Tilottama*, was only a partial success; but his great epic which followed in 1861, the *Meghanad-Badha*, took the Indian world by surprise, and at once established his reputation as the greatest poet of his age and country. He took his story from the old Sanskrit epic, the *Ramayana*, but the beauty of the poem is all his own, and he imparted to it the pathos and sweetness of Eastern ideas and the vigour and loftiness of Western thought. In 1862 Madhu Sudan left for Europe. He lived in England for some years, and was called to the bar; and in 1867 returned to his country to practise as a barrister in Calcutta. But the poet was unfitted for a lawyer's vocation; his liabilities increased, his health failed, his powers declined. He still wrote much, but he wrote nothing that will be remembered. His brilliant but erratic life ended in a Calcutta hospital on 29th June 1873. Among Madhu Sudan's most intimate friends may be mentioned the great reformer Iswar Chandra Vidyasagar, who often helped him in his difficulties, and the poet Hem Chandra Banerjee, who wrote an appreciative critique on his great epic. Among the young Indians who were studying in England in the 'sixties with Madhu Sudan, a few rose to distinction subsequently. One of them, Satyendra Nath Tagore, was the first Indian who entered the Civil Service of India; and two others, Mano Mohan Ghosh and Umesh Chandra Bonnerjee, were called to the bar, rose to a considerable practice in Calcutta, and were honoured leaders among their countrymen. (R. C. D.)

Madison, a city of Indiana, U.S.A., capital of Jefferson county, on the Ohio river and the Pittsburg, Cincinnati, Chicago, and St Louis railway, in the south-eastern part of the state, at an altitude of 450 feet. It has

much commerce by rail and river, and varied manufactures. Population (1890), 8936; (1900), 7835.

Madison, a city of Wisconsin, U.S.A., capital of the state and of Dane county, on the peninsula between Lakes Monona and Mendota, in the southern part of the state, at an altitude of 870 feet. It is regularly laid out on an undulating site, and is divided into eight wards. It is on three railways—the Chicago and North-Western, the Chicago, Milwaukee, and St Paul, and the Illinois Central. It is the seat of Wisconsin state university, which in 1900 had 137 instructors and 1841 students. Population (1890), 13,426; (1900), 19,164, of whom 3362 were foreign-born and 69 were negroes.

Grand Total	150,798	39,331,062	20,953,337	21,445,594	42,398,931	281

Between 1881 and 1891 the population increased by more than 15 per cent. in British territory, and by more than 10 per cent. in native states, and between 1891 and 1901 by 7.2 and 13.2 per cent. respectively. The high rate of increase in the earlier period is to be attributed mainly to recovery from the famine of 1876-78, and partly to more accurate enumeration in the "agency" tracts. The average density ranges from 605 persons per square mile in the fertile delta of Tanjore to only 116 in the barren uplands of Karnul and in the Nilgiris.

Classified according to religion, and excluding native states, Hindus numbered 31,998,309 in 1891, or 90 per cent. of the total population, being a higher proportion than in any other province. Mahommedans numbered 2,250,386, or only 6 per cent., though they have increased more rapidly than Hindus. Christians numbered 865,528, or 2.4 per cent., of whom 13,462 were Europeans and 26,642 Eurasians, leaving 825,424 for native converts, chiefly in the southern districts of Tinnevelly, Madura, Tanjore, Trichinopoly, and South Canara. In the native

under the administration of a governor. It occupies the entire south of the peninsula. Politically, it includes the Laccadive Islands, off the Malabar coast, in the Indian Ocean. Total area (including native states), 150,798 square miles; population (1891), 39,331,062; (1901), 42,398,931, showing an increase of 7.7 per cent. The capital is Madras city, from which the province takes its name. The "agency" tracts in the hilly interior of the northern Circars are administered on a special system, and for revenue purposes a considerable difference still prevails between the *zamindari* estates scattered throughout the presidency and the ordinary *rayatwari* lands.

The following table gives the area and population of the several districts and native states of Madras in 1891 and 1901:—

states the proportion of Christians rose as high as 19 per cent. Jains, with whom Buddhists are included, numbered 28,461; "others," 487,756, chiefly aboriginal tribes in the "agency" tracts. The languages spoken—all of the Dravidian family—are Telugu in the north-east, Tamil in the south, Malayalam in the west, and Canarese in the central plateau.

Agricultural statistics are not available for the *zamindari* estates, which occupy nearly 27 per cent. of the total area of the presidency, paying an average revenue of R.0.4.3 per acre. On *rayatwari* lands the average incidence of land revenue is R.1.14.4 per assessed acre and Rs.2.4.10 per cultivated acre. In 1897-98 the total cultivated area was 24,247,617 acres, of which 2,961,377 acres were cropped more than once. The irrigated area was 5,875,374 acres, of which nearly one-half was irrigated from Government canals. The principal crops are rice (grown chiefly along the coast); the two kinds of millet (here called *cholam* and *cumbu*); *ragi* (*Eleusine corocana*), chiefly in the uplands; pulse, oil-seeds, cotton, indigo, sugar-cane, and tobacco. In 1897-98 the area under coffee was 64,402 acres, chiefly in the districts of the Nilgiris, Malabar, Salem, and Madura; the area under tea was 7722 acres, almost entirely in the Nilgiris.

The Madras system of irrigation has been most successful in

the case of the three great eastern rivers, the Godavari, Kistna, and Cauvery. Each of these is intercepted by an *anicut* or dam at the head of its delta, from which canals diverge on each side for navigation as well as irrigation. The scheme for diverting the waters of the Tungabhadra (a tributary of the Kistna) over the thirsty uplands of Karnul has proved a failure, and the full result of the bold project of leading the Periyar river through a tunnel across the watershed of the Travancore hills on to the plain of Madura remains to be seen. In 1897-98 the total receipts from nine "major" works amounted to Rs.73,37,055, and the working expenses to Rs.17,90,996, showing a profit of Rs.55,46,059, or an average of 8.4 per cent. on a capital outlay of Rs.6,18,72,013. In addition, 27 "minor" works yielded a profit of Rs.7,52,785, or 4 per cent. on a capital outlay of Rs.1,69,73,752.

Madras possesses no special industry, like the cotton of Bombay or the jute of Bengal. In 1897 the total number of factories under inspection was 71, employing 31,197 operatives, of whom 2892 were women and 2216 children. Cotton-mills numbered 11, with 1705 looms and 274,254 spindles, employing 12,099 hands. The out-turn of yarn was 32,515,445 lb, chiefly of counts between Nos. 10 and 21; the out-turn of woven goods was 5,320,781 lb, chiefly tea-cloths, &c. There is one hemp mill at Vizagapatam, employing 823 hands; three breweries on the Nilgiri Hills, with an out-turn of 341,000 gallons; a flourishing sugar factory in Ganjam; and several tile-works on the Malabar coast. The manufacture of cigars has become an important industry in the districts of Madura and Trichinopoly. One factory alone produces 15 million cigars a year, valued at Rs.4,50,000.

The presidency is well supplied with railways, which naturally have their centre in Madras city, the chief seaport. The Madras railway connects with Bombay and Bangalore, and also crosses the peninsula to Calicut on the western coast. The South Indian serves the extreme south, with its terminus at Tuticorin. The Southern Mahratra traverses the Deccan districts; and the East Coast line, through the Northern Circars, has brought Madras into direct communication with Calcutta.

As might be expected from its double line of coast, the sea-borne trade of the presidency is less concentrated at its capital than is the case with either Bengal or Bombay. Only about 43 per cent. of the total is conducted at the port of Madras, the Malabar coast having 26 per cent., the Northern Circars 12 per cent., and Tinnevely district 12 per cent. The following table gives the value (in tens of rupees) of the foreign exports and imports of merchandise only for the years 1877-78 and 1897-98:—

	Imports.	Exports.
1877-78 . . .	Rx.3,694,712	Rx.5,565,549
1897-98 . . .	7,003,974	11,432,396

Thus both imports and exports approximately doubled in twenty years, showing a more rapid increase than either Bengal or Bombay. But the rate of increase was highest during the first half of the period, exports in particular having been checked by the bad seasons of 1896-98.

The following is the value (in the tens of rupees) of each of the principal articles of import and export in 1897-98:—

Imports:—Cotton piece-goods, Rx.1,813,411; cotton twist, Rx.1,027,642; railway materials, Rx.665,248; wrought metals, Rx.573,402; machinery, Rx.322,351; mineral oils, Rx.274,608; spices, Rx.232,291; liquors, Rx.202,271; apparel, Rx.194,964; hardware and cutlery, Rx.172,031; provisions, Rx.128,000. Exports:—Hides, Rx.3,106,102; coffee, Rx.1,494,261; rice, Rx.1,207,247; indigo, Rx.1,066,445; raw cotton, Rx.852,399; cotton goods, Rx.768,302; oil-seeds, Rx.360,706; spices, Rx.314,996; sugar, Rx.263,090; oils, Rx.248,984; coir manufactures, Rx.237,356.

As compared with previous years, the imports of cotton goods show little change. Piece-goods reached their maximum (Rx.2,546,196) in 1894-95, and twist (Rx.1,156,548) in 1888-89. Railway materials, wrought metals, machinery, mineral oils, hardware, and cutlery all increased steadily during the ten years ending 1898. The foreign imports of coal suddenly dropped by one-half, owing to competition from the Bengal mines, which now supply 80 per cent. of the amount consumed in the railways and factories of Madras. Among metals (wrought and unwrought) iron accounts for Rx.334,418, copper for Rx.178,328, and steel for Rx.60,088.

Under exports, the most noticeable feature is the large proportion of the total (more than one-fourth) contributed by hides, which doubled in the last ten years of the 19th century. The exports of rice, which are mainly to Ceylon, have also doubled. Coffee and indigo, though variable crops, are both fairly maintained. Raw cotton shows a heavy decline, which was continuous during the four years ending 1897-98. It reached its maximum (Rx.2,495,773) in 1889-90. Cotton goods, which consist chiefly of coloured cloth sent to Ceylon, the Straits Settlements, and Burma, are fairly well maintained. Sugar shows a heavy decrease, due to a bad season.

The United Kingdom has maintained its trade with Madras more successfully than with Bombay. The imports from the United Kingdom increased during the ten years 1887-88 to 1897-98, though the proportion to the total fell from 85 to 78 per cent. The exports to the United Kingdom actually decreased, and the proportion to the total fell from 60 to 43 per cent. The special feature of Madras trade is the large exportation to Ceylon, which more than doubled between 1888 and 1898, and now forms 20 per cent. of the total. It consists mainly of cotton piece-goods, rice, fish, and other provisions.

The value of the coasting trade of Madras in 1897-98 was as follows (in rupees):—Ports within the presidency—imports Rs.1,77,54,948; exports, Rs.1,79,63,838. Ports outside the presidency—imports, Rs.4,24,29,976; exports, Rs.3,27,18,949. Total—imports, Rs.6,01,84,924; exports, Rs.5,06,82,787.

The administration of the Madras presidency is conducted by a governor and a council, consisting of two members of the civil service, who are appointed by the Crown for a term of five years. The secretariat includes a chief secretary, a secretary, two under-secretaries, and an assistant. There is a board of revenue of three members. The number of districts is 22, each under the charge of a collector, with sub-collectors and assistants. The districts are not grouped into divisions or commissionerships, as in other provinces. In 1898 the number of covenanted civilians on the Madras establishment was 162. The total number of civil and revenue judges was 310, and of magistrates of all sorts, 725. The total strength of the police was 22,747 officers and men, being 1 policeman to every 8 square miles of area and to every 2167 of the population.

Since the reorganization of the Indian army in 1894 the Madras command, under a lieutenant-general, comprises Burma, Mysore, Haidarabad, and Belgaum in Bombay, in addition to the Madras presidency, with headquarters at Ootacamund in the Nilgiri Hills. It consists of two first-class and six second-class military districts, of which Madras and the southern district alone lie entirely within the presidency. In 1898 the strength of the Madras command was 12,447 Europeans and 29,410 natives; total, 41,857. In addition, there were 5710 enrolled volunteers.

For legislative purposes the council of the governor is augmented by additional members, not exceeding 20, who are nominated by the governor for a term of two years. Of these not more than 9 may be officials, and 7 are nominated on the recommendation of the Madras corporation, groups of municipalities and district boards, selected public associations, and the senate of the Madras University. Members of this legislative council enjoy the right of interpellation and of discussing the annual financial statement.

Excluding Madras city, the number of municipalities in the presidency is 58, with an aggregate population of 1,687,563 in 1891. In 1898 the total number of members was 868, of whom 367 were elected by the ratepayers, and 727 were natives. The aggregate municipal income (including loans) was Rs.29,21,107, of which Rs.7,09,610 was derived from rates, Rs.3,58,951 from tolls, and Rs.2,86,403 from Government contributions. The average incidence of taxation (including tolls) was 14 annas per head. The aggregate expenditure was Rs.35,02,705, of which Rs.10,41,099 was devoted to public works (including water-supply), Rs.10,16,941 to medical services and sanitation, Rs.3,42,801 to education, and Rs.2,57,579 to lighting and miscellaneous.

The principle of local devolution is carried somewhat farther in Madras than in other provinces. At the bottom are union *panchayats* or village committees, whose chief duty is to attend to sanitation. In 1898 these numbered 376, with 3551 members. Above them come 80 *taluk* or sub-divisional boards, with 1122 members. At the head of all are 21 district boards, with 647 members, of whom 296 were elected by the *taluk* boards. In 1897-98 the aggregate income of local funds (including loans) was Rs.88,27,640, of which Rs.63,66,768 was derived from rates and Rs.3,15,143 from a provincial grant. The aggregate expenditure was Rs.83,93,060, of which Rs.35,29,227 was devoted to public works, Rs.18,73,480 to medical and sanitary purposes, and Rs.10,95,782 to education.

The total net revenue of Madras for 1897-98 (in tens of rupees, distributed under the three heads of imperial, provincial, and local, was Rx.7,304,601, Rx.2,811,486, and Rx.1,049,068 respectively, or a total of Rx.11,165,155, the corresponding totals for the expenditure being Rx.3,371,870, Rx.2,811,684, Rx.1,048,870, and Rx.7,232,424.

The following table gives the gross revenue under five principal heads for the years 1887-88 and 1897-98:—

	1887-88.	1897-98.
Land . . .	Rx.4,527,937	Rx.4,937,748
Stamps . . .	597,161	842,026
Excise . . .	973,906	1,462,010
Forests . . .	137,492	213,649
Assessed taxes . . .	168,146	266,446

These figures show steady progress, especially under excise and assessed taxes. The increase of land revenue is the more noticeable as 1897-98 was a bad season.

The following table gives the chief statistics of education in Madras for the years 1886-87 and 1896-97:—

	1886-87.		1896-97.	
	Schools.	Pupils.	Schools.	Pupils.
Colleges	35	3,323	43	4,423
Secondary schools	747	60,856	748	90,610
Primary schools	14,005	384,888	20,792	617,886
Special schools	82	3,022	122	5,386
Private institutions	1,788	30,853	5,167	104,548
Total	16,717	488,942	26,872	822,853

It is noticeable that pupils have increased more rapidly than institutions, especially in the case of secondary schools, which tends to make the stronger institutions more efficient. If we compare the number of pupils with the estimated population of school-going age (15 per cent. of the total population), the increase during the ten years was from 10·6 to 15·4 per cent. Taking girls alone, the number at school increased from 65,137 to 116,747, while the proportion to the female population of school-going age rose from 2·8 to 4·3 per cent. A peculiarity of the Madras system is that English is taught even in primary classes, so that the total number of pupils learning English in 1896-97 was 141,625, being one in every 38 of the population of school-going age. Another feature is the extent to which Brahmans take advantage of the opportunities open to them. Out of every 16 Hindus in colleges, 15 are Brahmans; and out of 103 Hindus in high schools, 94 are Brahmans.

The following table gives the expenditure on education for the same years, according to sources:—

	1886-87.	1896-97.
Provincial revenues	Rs.13,48,923	Rs.18,75,783
Local funds	5,55,762	8,74,237
Municipal funds	1,63,560	2,33,373
Fees	14,98,366	20,22,226
Other sources	9,95,969	16,81,605
Total	45,62,580	66,87,224

Expenditure has not grown quite so fast as the number of pupils. But here, as in other provinces, the larger share of the increased expenditure has come from fees and "other sources," which mainly consist of mission contributions. Altogether, the proportion of the total borne by public funds has fallen from 45·3 to 44·6 per cent. In secondary schools alone public funds contribute less than one-fourth.

Madras has been fortunate in almost entirely escaping the plague, despite serious outbreaks in Mysore and the border district of Dharwar in Bombay. The total number of deaths from plague recorded throughout the presidency down to April 1899 was only 1804. Madras was little affected by the famine of 1899-1900. In April 1900 the total number of persons in receipt of relief was only 18,000, chiefly in the Deccan districts, which had suffered severely in the famine of 1896-97.

For 1897 the total number of deaths registered was 827,525, of which 292,292 were ascribed to fevers and 143,445 to cholera. The death-rate was 25·4 per thousand, compared with a mean of 20·4 during the previous five years. The registered birth-rate was 28·7 per thousand. The number of persons successfully vaccinated was 1,067,319.

(J. S. CO.)

Madras City, the capital of Madras presidency and chief seaport on the eastern coast of India, situated in 13° 4' N. and 80° 17' E. The city, with its suburbs, extends nine miles along the sea and nearly four miles inland, intersected by the little river Cooum. Area, 29 square miles; population (1881) 405,848; (1891), 452,518; (1901), 509,397; showing an increase of 11 per cent. between 1881 and 1891 and of 12·57 per cent. between 1891 and 1901. Madras is thus the third city in India. Classified according to religion, Hindus in 1891 numbered 358,997, or 79 per cent.; Mahommedans, 53,184, or 12 per cent.; Christians, 39,742, or 9 per cent., of whom 4229 were Europeans and 11,943 Eurasians, leaving 23,570 for native converts; Jains (including Buddhists), 410; and "others," 185.

Madras possesses no special industries. There are four cotton-mills, with 1595 looms and 125,220 spindles, employing 6031 hands; a large cement work, several iron-foundries, and two cigar factories. Large sums of money have from time to time been spent upon the harbour works, but without any great success. The port still remains practically an open roadstead, and the P. and O. steamers ceased to call in 1898. Madras conducts about 56 per cent. of the foreign trade of the presidency, but a much smaller share of the coasting trade. In 1897-98 the total sea-borne trade, both merchandise and treasure, was valued at Rs.12,98,85,783, of which Rs.10,50,17,710 represents foreign trade. The number of vessels that entered and cleared with cargo in the foreign trade was 279, with an aggregate tonnage of 523,713. Including coasting trade, the number of vessels was 711, with a tonnage of 1,158,897, which paid dues to the amount of Rs.1,09,495. The total income of the harbour trust was Rs.7,20,000, and the total expenditure Rs.7,30,000, including Rs.2,24,000 for interest and Rs.1,00,000 for repayment of advances.

The municipal government of the city was framed by an Act of the Madras legislature, passed in 1884. The governing body consists of 32 commissioners, of whom 24 are elected by the ratepayers, together with a paid president. The number of registered voters in 1898 was 5720, being 12·5 per thousand of the total inhabitants. At contested elections in ten wards about half the registered voters exercised the franchise. In 1897-98 the total income (excluding loans, &c.) was Rs.13,60,000, of which Rs.10,30,000 was derived from rates and taxes, the incidence of taxation being Rs.2·27 per head. The principal tax is a rate of 10 per cent. on houses and lands. The total expenditure was Rs.17,03,000, of which Rs.7,97,000 was devoted to public works, including a new drainage scheme; Rs.3,83,000 to sanitation and medical purposes; Rs.11,890 to education; and Rs.2,06,000 to interest and repayment of debt. The total amount of debt outstanding was Rs.12,18,400, almost all raised for water-works and drainage. A new system of water-supply is projected. The old system supplied 480 million cubic feet of water during the year.

The Madras University was constituted in 1857, as an examining body, on the model of the University of London. During the five years ending 1897 the total number of candidates who matriculated was 5546, while 2401 graduated B.A., 538 passed examinations in law, 233 in medicine, and 38 in engineering. The chief educational institutions in Madras city are: the Presidency College (with 395 students in 1897), six missionary colleges and one native college; the medical college, the law college, the college of engineering, the teachers' college, and the college of agriculture (in the suburb of Saidapet), all maintained by Government; the Government school of arts (with 674 pupils learning drawing); 18 high schools for boys, one of which is maintained by Government for Mahommedans; 11 high schools for girls. In 1896-97 the total number of pupils under instruction was 40,315, the proportion to the population of school-going age being 89 per cent. for boys and 30 per cent. for girls. For 1897 the death-rate was 35·8 per thousand, compared with a mean of 40·2 during the previous five years; the birth-rate was 41·6 per thousand.

(J. S. CO.)

Madrazo y Kunt, Don Federico de (1815-1894), Spanish painter, was born in Rome on 12th February 1815. He was the son of the painter Madrazo y Agudo (1781-1859), was baptized at St. Peter's, Rome, and received his first instruction from his father. While still attending the classes at the Academy of San Fernando, he painted his first picture, "The Resurrection of Christ"

(1829), which was purchased by Queen Christina. Not long afterwards he painted "Achilles in his Tent," and subsequently presented to the Academy "The Continnence of Scipio," which secured him admission as a member "for merit." While decorating the palace of Vista Alegre, he took up portraiture. In 1852 he went to Paris, where he studied under Winterhalter, and painted portraits of "Baron Taylor" and of "Ingres." In 1837 he was commissioned to produce a picture for the gallery at Versailles, and painted "Godfrey de Bouillon proclaimed King of Jerusalem," which was finished in 1839. The artist then went to Rome, where he worked at various subjects, sacred and profane—among others, "The Three Holy Women at the Sepulchre." Then he painted "Maria Christina in the Dress of a Nun by the Bedside of Ferdinand III." (1843); "Queen Isabella," "The Duchess of Medina-Cœli," and "The Countess de Vilchès" (1845-47), besides a number of portraits of the Spanish aristocracy: "King Don Francisco," the Duchesses of Alba and of Seville, the Countess de Robert-sart, and P. de Madrazo; some of these portraits were sent to the Exhibition of 1855. He had received a third-class medal in 1838, two first-class medals in 1845 and 1855, and the decoration of the Legion of Honour in 1846. He had been corresponding member of the Paris Academy of Fine Arts since 10th December 1853, and in 1873, on the death of Schnorr the painter, he was chosen foreign member. After his father's death he succeeded him as director of the Prado Gallery and president of the Academy of San Fernando. He assisted his brother, Don Pedro, in preparing the catalogue of the Gallery which was published in 1873. He originated in Spain the production of art reviews and journals, such as *El Artista*, *El Renacimiento*, and *El Semanario Pintoresco*. He was corresponding member of the Academies of Belgium and of St Luke at Rome, and was the writer of various historical and critical papers. He died at Madrid on the 11th of June 1894. His brother, DON LOUIS DE MADRAZO, is also known as a painter, chiefly by his "Burial of Saint Cecilia" (1855). Don Federico's best-known pupil is his son, DON RAIMUNDO DE MADRAZO, born in 1841.

(H. FR.)

Madrid, a province of central Spain; area, 2997 square miles. The population rose from 682,644 in 1887 to 737,444 in 1897. The average density of the population is thus about 246 per square mile, but the majority of the inhabitants are within the municipal boundaries of the capital, and the density outside is barely 62 per square mile. The birth-rate averages 38.3 per thousand, the death-rate, 38.4, and the proportion of illegitimate births only 2.63 per cent. About 1100 emigrate annually. The province is divided into 18 administrative districts and 195 parishes. It is included for military purposes within the first army corps commanded by the captain-general of Madrid; for judicial purposes in the Court of Appeal of Madrid, and for ecclesiastical in the diocese of Madrid Alcala. Besides the local lines, all the great railways in the kingdom converge in this province, and it contains in all 221 miles of line. No province in Spain contains a greater number of persons paying the industrial and commercial rates. Local industries, not only in the town and suburbs of Madrid, but in the rest of the province, have developed very much, especially manufactures of chocolate, alcohol, porcelain and pottery, soap, flour, glass, candles, paper, iron, tanning, and saw-milling. Agriculture and wine-growing have also progressed; vines have been extensively planted near the capital, and agricultural methods and machinery improved. Efforts have been made by the various authorities to cover the large stretches of waste ground and commons with pines and other trees.

Much timber is extracted from the forests of the northern and north-eastern part of the province for building purposes and for firewood and charcoal. The royal domains of Escorial, Aranjuez, and El Pardo and the preserves of the nobility are all well wooded, and contain much game. In 1898 the province had 14,094 horses, 23,473 mules, 8463 asses, 19,396 cattle, 260,462 sheep, 37,638 goats, and 11,695 pigs. The south-eastern districts are the best irrigated, and produce in abundance fruit, vegetables, wheat, olives, esparto grass, and excellent wine, red and white. There are more than 60,000 acres well irrigated, and over two millions and a quarter well cultivated, wheat being grown on 167,389 acres, other cereals on 203,252 acres, leguminous crops on 36,922 acres, vines on 158,502 acres, and olives on 18,415 acres.

Madrid, the capital of the above province, and of the kingdom of Spain, situated on the left bank of the river Manzanares. Its population increased to 472,228 in 1887, and to 512,150 in 1897. In the latter year the births were 15,413 (7833 males, 7580 females), being an average for the twelvemonth of 31.85 per thousand inhabitants. The deaths in 1897 were 14,594 (7579 males, 7015 females), 6111 being those of children under ten years of age, the average for the year per thousand inhabitants being 40.50. There is a very great difference between the death-rate in winter and in summer. In the former season it is often as high as 80 daily, dropping to between 20 and 30 in summer. The death-rate is lower than that of 22 provincial capitals. The average proportion of illegitimate births in 1897 was 6.86 per cent., but in the most populous district there were 1636 illegitimate births against only 1339 legitimate.

The public buildings were extensively restored and improved between 1885 and 1900. Foremost must be mentioned the Biblioteca National, standing near the Mint on the Paseo de Recoletos, of which the first stone was laid in 1866, and which was only completed in 1892. Not only the National Library, with its important collections of MSS. and documents, but the Archæological Museum, the Museums of Modern Painting and Sculpture, and the Fine Arts Academy of San Fernando, are within its walls. The total cost of the building was £640,000. The art exhibition in connexion with the celebration of the fourth centenary of the discovery of America by Columbus was held within it in 1892. The royal carpet and tapestry manufactory has been transferred to a site in the Pacifico suburb. A large and handsome building has been erected near the Retiro Park for the Ministers of Public Works, Agriculture, Industry, Commerce, and Fine Arts, and Education; and nearly opposite stands the new station of the Southern Railway Company. The Great Northern and the Spain to Portugal railway companies have also replaced their ugly old stations by very spacious handsome structures, much resembling those of Paris. In 1896 the Royal Exchange was installed in a large monumental building with a fine colonnade facing the Dos de Mayo monument, not far from the Museum of Paintings. In the same part of the city, the Medina-Cœli Palace has disappeared to make room for new streets. In the Salon del Prado the duke of Sexto's palace at the corner of Alcala Street, opposite the War Office, has made way for the new offices of the Bank of Spain, a heavy, imposing building 290 yards long. At each extremity of the Prado two large circular "squares" have been made out of the older and irregular ones, and the fountains of Cibeles and Neptune have been moved to the centre of the Plazas de Castelas and de Canovas. The north and north-east of the city—the new suburbs—have developed past the Retiro Park as far as the Bull-ring, built in 1874 to hold 16,000 spectators, and have covered all the vast space included between the Retiro, the Bull-ring, the long Castellana Drive to the race-course, and the Exhibition building. On the slopes of the other side of the Castellana, and away along what were the northern

limits of Madrid in 1875, the modern suburbs have extended to the vicinity of the fine cellular prison that was built at the close of the reign of King Alphonso XII. to replace the gloomy building known as El Saladero. It can hold nearly 1000 male prisoners, and serves also as a house of correction for offenders undergoing short terms of imprisonment. The prison for females calls for considerable improvement. The new parts of the capital, with their broad streets and squares, and their villas sometimes surrounded with gardens, the noble mansions of the upper classes, the boulevards lined with rather stunted trees, and the modern public buildings, all resemble the similar features of other European capitals, and contrast with the old Madrid that has preserved so many of its traits in architecture, popular life, and habits. Some of the streets have been widened slightly, and in many thoroughfares new houses are gradually studding the background formed by the ugly irregular dwelling-places of the 18th and earlier centuries. This contrast is to be seen especially in and about the Calle Mayor, the Plaza Mayor, the Calle Toledo, the Rastro, and the heart of the city. There are, however, several buildings, dating from times long past, which are worthy of admiration—grand, old-world residences of the ancient nobility, massive convents, the episcopal palace, the Town Hall opposite the palace of the Lujanes, the Government House, the house of the seven chimneys that was the residence of Charles I. of England and Buckingham in 1623, and the many ministerial offices installed in old conventual buildings. The churches of Madrid underwent alteration in the last quarter of the 19th century. When the capital was separated from the archiepiscopal see of Toledo, and erected into a bishopric, styled of Madrid Alcala, the church of San Isidro was made the cathedral. The church of the old Franciscan convent, San Francisco el Grande, has been splendidly restored by the State at considerable expense. Its dome, chapels, and walls were covered with remarkable works, frescoes, and paintings by most of the leading Spanish artists of the last half of the 19th century. The modern chapels and churches of the capital are not worth noticing, except the church of the Almudena, founded by King Alphonso XII. close to his palace, which, however, has progressed so slowly that only its crypt and the base of its massive walls and columns of solid granite were complete in 1901. The Campo de Moro, as the slope below the palace down to the river road is styled, was greatly improved by the Queen Mother (Maria Christina). Some noble timber has been sacrificed, and a modern park and gardens substituted. Little progress has been made in the reconstruction of the historic church of the Virgin of Atocha, which it was at one time intended to make a pantheon for the worthies of modern Spain, several of whom, like Castanos and Palafox, the heroes of the War of Independence against Napoleon I., and Prim, the chief of the Revolution of 1868, had found there a last resting-place. The Courts of Justice are still held in the 17th-century convent of Las Salesas Reales. The Houses of Parliament are in separate buildings. The Congreso, or House of Deputies, which has met since 1843 in a large handsome structure in the Carrera San Geronimo, has a very important library; the Senate is in an old convent of the Augustine order (restored), and has fine modern paintings, and also a library of 20,000 volumes. The squares of the Spanish capital are adorned with many statues of kings, statesmen, soldiers of the War of Independence, and great writers like Calderon and Cervantes; and not a few of the residences or birthplaces of eminent men have been redeemed from oblivion and distinguished by slabs of marble with inscriptions. There are no less than fourteen theatres and two circuses, besides the Royal Opera House and the Retiro Gardens,

also with a theatre that is the chief summer resort at night.

Few capitals have more extensively developed their electric and horse tramways, gas and electric light companies, and telephones. Much was done to improve the sanitary conditions of the city in the last twenty years of the 19th century. The streets are deluged three times a day with fire-hose, but even that has little effect upon the dust. Unfortunately the water-supply, which used to be famed for its abundance and purity, is now wholly insufficient owing to the growth of the city. The reservoirs of the Lozoya canal, 32 miles long, are quite inadequate for the requirements of modern Madrid, and they have been kept in such an unsatisfactory state that in 1898 and 1899 for several months the water not only was on the point of giving out, but at times was of such inferior quality that the people had recourse to the many wells and fountains still extant in the ten districts of the Spanish capital. A decided improvement has been made in the burial customs. No bodies are allowed to be interred in the churches and convents. Some of the older burial grounds in the northern suburbs have been closed altogether, and in those which remain open, few coffins are placed in the niche vaults in the depth of the thick walls, as was once the practice. A large modern necropolis has been established a few miles to the north-east, where most burials now take place, and the older cemeteries must all be closed at no distant date. Madrid had a British cemetery more than thirty years before the end of the 19th century. The city contains also a British Embassy chapel, a German chapel, and several Spanish Protestant chapels attended by over 1200 native Protestants, while the Protestant schools, chiefly supported by British, German, and American contributions, are attended by more than 2500 children.

The first Protestant bishop of Madrid was ordained in 1895 by Archbishop Plunkett of Dublin. The Spanish educational establishments have also been considerably improved. The university had in 1897 a staff of 102 professors and 21,500 students. Of these 11,500 belonged to the faculty of law, 8000 to that of medicine, 150 to that of science, 1650 to pharmacy, and 200 to philosophy and literature. Besides the special superior schools there are a self-supporting institute for preparing girls for the higher degrees and for certificates as primary teachers, and two institutes for secondary education, one attached to the university and the other conducted chiefly by ecclesiastics. There are now more than 120 primary, State, and municipal schools, educating 58,000 boys and 49,500 girls. The Jesuit schools of Chamartin and the Scolapian fathers are conspicuous among private institutions. The charitable institutions have been remarkably improved. The Princess Hospital has been completely restored on modern methods, and can accommodate several hundred patients. The old contagious diseases hospital of San Juan de Dios has been pulled down and a fine new hospital built in the suburbs beyond the Retiro Park, to hold 700 patients. The Military Hospital has also been demolished and a very good one built in the suburbs. The old Provincial Hospital, to hold 1200 patients, is, however, in anything but a satisfactory condition. There are now in all twenty hospitals in Madrid, and a lunatic asylum on the outskirts of the capital, founded by one of the most eminent of Spanish surgeons, and conducted by him on a scale which enables the institute worthy to compare with those in other European capitals. The rate of mortality in the three founding hospitals is high, the services being seriously crippled by lack of funds. New buildings have been provided for the orphanages, and for the asylums for the blind, deaf and dumb, incurables, and aged paupers. There are hospitals supported by the French, Italian, and Belgian colonies; these are old and well-endowed foundations. Public charity generally is very active. In Madrid, as in the rest of Spain, there has been an unprecedented increase in convents, monasteries, and religious institutions, societies, and Catholic workmen's clubs and classes.

Apart from private institutions for such purposes, the State maintains in the capital a savings bank for the poorer classes, and on the other hand acts the rôle of pawnbroker for their benefit. The commerce of the capital is chiefly important in the retail trade, and the mercantile and industrial classes are organized in "guilds," which themselves collect the lump sum of taxation exacted by the exchequer and the municipality, from each *gremio* or class of taxpayers. The working classes also have commercial and industrial *circulos* or clubs that are obeyed by the guilds with great *esprit de corps*, a chamber of commerce and industries, and associations of "productions" to defend their economic interests. The industries of the capital have developed extraordinarily since 1890. In the town and within the municipal boundaries in the suburbs many manufactories have been established, giving employment to more than 30,000 hands, besides the 4000 women and girls of the Tobacco Monopoly Company's factory. Among the most important factories are those which make every article in leather, especially cigar and card cases, purses and pocket-books, all duly stamped Paris, London, and

Vienna, to be sold more profitably in the shops of Madrid. Next come the manufactures of fans, umbrellas, sun-shades, chemicals, varnishes, buttons, wax candles, beds, cardboard in all shapes, porcelain, coarse pottery, matches, baskets of all kinds, sweets and preserves, gloves, guitars, biscuits, furniture, carpets, corks, cards, carriages, jewellery, drinks of all kinds, plate, and plated goods. There are also tanneries, saw and flour mills, glass and porcelain works, soap works, brickfields, paper mills, zinc, bronze, copper, and iron foundries. The working classes are strongly imbued with Socialistic ideas, and are organized in large societies. The union of masons alone numbers 15,000 members. The strikes of these workmen and their May Day demonstrations have often been troublesome. Order is kept by a garrison of 12,500 men in the barracks of the city and cantonments around, and by a strong force of civil guards or gendarmes quartered in the town itself. The civil and municipal authorities can employ besides the gendarmes the police, about 1400 strong, and what is called the *guardias urbanas*, another police force whose special duty it is to regulate the street traffic and prevent breaches of the municipal regulations. There is not, on the average, more crime in Madrid than in the provinces.

(A. E. H.)

Madridejos, a town of Spain, in the province of Toledo, on the borders of Ciudad Real, 65 miles south of Madrid. The surrounding country is fertile, producing wheat, wine, oil, and hemp. There are mines of copper and lead in the neighbourhood. The industries are leather and alcohol. Population (1887), 6579; (1897), 6387.

Madura, a city and district of British India, in the Madras presidency. The city is on the right bank of the river Vaigai, and is a station on the South Indian railway, 345 miles south-east of Madras. Population (1881), 73,807; (1891), 87,428; (1901), 105,501. The municipal income in 1897-98 was Rs.1,81,470. It has two aided colleges, with 120 students in 1896-97; three aided high schools, with 1410 pupils; Jesuit and American Protestant missions; eight printing-presses, issuing one English newspaper and two mission periodicals; five reading-rooms and literary institutes; and a cotton mill, with 36,344 spindles, employing 1750 hands.

The district of MADURA has an area of 8808 square miles. Population (1881), 2,168,680; (1891), 2,608,404; (1901), 2,832,104, showing an increase of 20 per cent. after the famine of 1876-77, which was felt here but slightly, and of 8.58 per cent. between 1891 and 1901; average density, 321 persons per square mile. The land revenue and rates in 1897-98 were Rs.34,28,552, the incidence of assessment being R.1.12 per acre; cultivated area, 1,009,253 acres, of which 276,170 were irrigated from tanks, &c., including 34,835 from Government canals; number of police, 1225; boys at school (1896-97), 50,328, being 27 per cent. of the male population of school-going age; registered death-rate, 23.7 per thousand. The principal crops are millet, rice, other food-grains, oil-seeds, cotton. Coffee is grown on the Palni Hills, to the extent of 6161 acres; tobacco chiefly in the neighbourhood of Dindigul, whence it is exported to Trichinopoly to be made into cigars. There are five cigar factories in the district, one of which employs 1000 hands, with an annual out-turn valued at Rs.4,50,000, and 149 saltpetre refineries. The only other large industry is that of coffee-cleaning. Madura is traversed by the main line of the South Indian railway. It has four small seaports, whose total trade (chiefly with Ceylon) was valued in 1897-98 at Rs.20,12,204. The most important irrigation work is that known as the Periyar project, which consists of a tunnel through the Travancore Hills, to convey the rainfall across the watershed, at a capital cost of Rs.85,29,000. In 1897-98 the irrigated area was 28,051 acres; the receipts were Rs.1,30,822, compared with an expenditure (including interest) of Rs.4,35,969.

Madura, an island of the East Indian Archipelago, separated by the strait of that name from the east end of Java. Being a continuation of the limestone range of northern Java, the island is of the same geological structure as Rembang and Surabaya. The formation of the coast and plains is Tertiary and recent alluvium. There are hills and ranges 1300 to 1600 feet high. The soil being poor, fishing and cattle-rearing are the chief means of subsistence. The cattle exceed 550,000, outnumbering the stock of cattle in any other residency of Java, and yielding an excess for export to Surabaya and east Java.

Besides rice, which is not grown in sufficient quantity for home consumption, and maize, Madura yields cocoa-nut oil and jati. There is no agriculture carried on for European proprietors or for the Government, but the manufacture of salt for the Government, abolished in other places, still continues in Madura. The Madurese often emigrate in thousands to other residencies of Java. The chief group of islands belonging to Madura are the Kangean and Sapudi Islands, yielding timber, trepang, turtle, pisang, and other products. Area, 1770 square miles. Population (1897), 1,652,580, of whom 1,646,071 were natives, 4252 Chinese, and 558 Europeans.

. See VETH. *Java*, vol. iii.—KIELSTRA, "Het Eiland Madoera," in *De Gids*, 1890.—VAN LENNEP, "De Madoereezen," in *De Indische Gids*, 1895, with detailed bibliography.

Madvig, Johan Nicolai (1804-1886), Danish philologist, was born on the island of Bornholm, 7th August 1804. He was educated at the Classical School of Frederiksborg and the University of Copenhagen. In 1826 he graduated with a dissertation *Emendationes in Ciceronis libros de legibus et Academicis*, and afterwards gained the doctor's degree with a thesis on some of the ancient commentators of Cicero. In 1828 he became reader, and in 1829 professor, of Latin language and literature at Copenhagen, and in 1832 was appointed university librarian. In 1848 Madvig began to take an active part in politics. He entered parliament as a member of what was called the "Eider-Danish" party, because they desired the Eider to be the boundary of the country. When this party came into power, Madvig became Minister of Education, and retained this post till 1851. In 1852 he became Director of Public Instruction. Some years later, from 1856 to 1863, Madvig was president of the Danish parliament and leader of the National Liberal party. With these brief interruptions the greater part of his life was devoted to the study and teaching of Latin and the improvement of the classical schools, of which he was chief inspector. As a critic he was distinguished for learning and acumen. He devoted much attention to Cicero, and revolutionized the study of his philosophical writings by an edition of *De Finibus*, published in 1839. He also edited *De Senectute* and *De Amicitia*, and several of the Orations. In 1860 he published his *Emendationes Livianæ*, followed by an edition of Livy, in which he and Ussing collaborated. He also worked at Lucretius and Juvenal, and published two volumes of emendations with the title *Adversaria critica ad scriptores Græcos et Latinos*. Perhaps his most widely known works are those on Latin grammar and Greek syntax, especially his Latin grammar for schools. In 1874 his sight began to fail, and he was forced to give up much of his work. He still, however, continued to lecture, and in 1879, when the University of Copenhagen celebrated its 400th anniversary, he was chosen rector for the sixth time. In 1880 he resigned his professorship, but went on with his work on the Roman Constitution, which was completed and published before his death. In this book Madvig takes a strongly conservative standpoint, and attacks Mommsen's views on Cæsar's programme of reforms. It is a clear exposition of its subject, though rather too dogmatic and without sufficient regard for the views of other scholars. Madvig died at Copenhagen on 13th December 1886.

(A. Z.)

Maestricht (in Dutch *Maastricht*), capital of the Dutch province of Limburg, at the influx of the Geer into the Maas, 19 miles by rail north-north-east of Liège. The railway, Maastricht-Aken, was in 1898 taken over by the State. Maestricht has a small museum of antiquities, and geological and palæontological collections; also several

technical schools. The industrial establishments embrace an earthenware and glass factory employing 3000 hands, factories for paper, firearms, and woollens, breweries, and distilleries. Population (1901), 34,182.

Maeterlinck, Maurice. See BELGIUM. (*Literature*).

Mafeking, a town of British South Africa, formerly the head kraal of the Barolong branch of the Bechuana nation, and still their largest station, but now chiefly important as the administrative centre of British Bechuanaland. It lies close to the Transvaal frontier, about the sources of the Molopo river, 96 miles north of Vryburg, on the Cape to Bulawayo trunk line, of which it is one of the busiest stations. It is situated nearly 200 miles due east of Johannesburg, and is memorable in South African warfare both as the point from which Dr Jameson started on his famous Raid on 28th December 1895, and still more for its heroic defence under Colonel (afterwards General) Baden-Powell against the Boers. The siege, which began soon after the outbreak of hostilities on 11th October 1899, lasted till 18th May 1900, when the place was relieved by Colonel Mahon.

Magdeburg, a town and first-class fortress of Prussia, capital of the province of Saxony, on the river Elbe, 88 miles by rail west-south-west of Berlin, an important railway junction, and one of the principal commercial and industrial towns in North Germany, as well as the headquarters of the 4th German Army Corps. It now includes also the fifth suburb of Wilhelmstadt on the west. Since the fortifications were pushed out in 1866 and 1888, new quarters have grown up on the north, south, and west, and the narrow crooked streets of the old town are being widened and straightened as occasion offers; but the principal thoroughfare, Der Breite Weg, still retains its 17th-century gable-ended houses. In the last years of the 19th century several new parks were laid out in the suburbs. Amongst the various modern buildings may be mentioned the post office, Imperial Bank, royal consistory hall (1891), and the municipal offices and library. A new building has been erected for the industrial art, natural science, and other collections, formerly housed in the Prince's Palace. The church of Our Lady was completely restored in 1890-91. The city is adorned with various monuments—an equestrian statue of the Emperor William I. (1897) by Siemering, one to Luther (1886), and another to Immermann (1899). It also possesses a couple of theatres, a branch (1889) of the Halle Agricultural College, an art school, a commercial school, an imperial orphanage, a teachers' seminary, a meteorological observatory, and a gaol. The first place amongst the industries is taken by the ironworks (one being a branch of the Krupp firm, the Grusonwerke, employing 3500 men), which produce naval armour, caissons, cannon, cranes, &c. Of almost equal importance are the sugar refineries and chicory factories. Then come factories for tobacco, chocolate, artificial manure, cement, varnish, chemicals, and pottery, rope-walks, distilleries, breweries, and various other branches. Magdeburg is the central market in Germany for sugar and chicory, but trades extensively also in cereals, fruit and vegetables (grown close to the city), groceries, cattle and horses, wool, cloth, yarn, leather, coals, iron wares, fats, and books. A new winter harbour, made at a cost of £400,000, is intended to promote the river traffic up and down the Elbe. Altogether an aggregate of 2½ million tons of merchandise passes Magdeburg, going upstream, and over ¾ million tons, going downstream, annually. Population (1885), 159,520; (1890), 202,234; (1900), 229,663. In 1887 the suburbs of Buckau and Neustadt were incorporated.

Magee, William Connor (1821-1891), bishop of Peterborough and archbishop of York, was born at Cork in 1821. His father was curate of the parish attached to the Protestant cathedral in that city. Young Magee entered Trinity College, Dublin, at the early age of thirteen, but nevertheless succeeded in obtaining a scholarship. His reading at college was rather discursive than profound, but he passed a brilliant examination in gaining Archbishop King's prize. He was instrumental in resuscitating the Trinity College Historical Society, which has done so much good work since. He was ordained to the curacy of St Thomas's, Dublin, but after two years evinced symptoms of consumption, and was sent for a time to Malaga. On his return he took a curacy at Bath, where his reputation rapidly grew. He was nominated to the incumbency of Kensington Chapel, Bath, but the appointment was vetoed by his rector, who is reported to have said, "I brought Magee here to fill my church. If he goes to Kensington Chapel he will empty it." He was, however, speedily appointed to the Octagon Chapel, where his fame continued to spread, and his extraordinary powers as a platform orator were displayed on many occasions. Some years afterwards he was made prebendary of Wells Cathedral, and in 1860 he had the offer of the important post of Quebec Chapel in London, on the resignation of Dr Goulburn, afterwards dean of Norwich. The delicate state of his health caused him to accept the living of Enniskillen almost immediately afterwards. In 1864 he was made dean of Cork and chaplain to the lord-lieutenant. Here he manifested those great gifts which ultimately raised him to a more exalted station: a powerful grasp of mental, moral, and political problems, combined with eloquence of a high order, illuminated with the most brilliant flashes of wit. In 1868 the question of the Disestablishment of the Irish Church came to the front, and Magee threw himself into the task of its defence with his usual energy and vivacity. The success of his orations caused Mr Disraeli to offer him the bishopric of Peterborough in a characteristic letter. He justified his appointment by his magnificent speech when the Disestablishment Bill reached the House of Lords in 1869, and then plunged into diocesan and general work in England. Here he was everywhere in request, and preached and published sermons on a variety of subjects, the most celebrated, perhaps, of these being his three remarkable sermons on Christian Evidence, in Norwich Cathedral in 1871. He took up the temperance question, and electrified the country by a declaration in the House of Lords that he would rather see "England free than England compulsorily sober," an utterance which the extreme advocates of total abstinence commented on most severely, leaving out, in a manner not uncommon with men in whom the judicial faculty is weak, the qualifying word "compulsorily," and representing the bishop as having cast a slur on sobriety. He was also a supporter of the movement for abolishing the recitation of the Athanasian Creed in the public services of the Church of England, believing, as he said, that the "presence" of the damnatory clauses, "as they stand and where they stand, is a real peril to the Church and to Christianity itself," and that those clauses "are no essential part" of the creed. The project was laid aside in consequence of the hostility of a large body of the clergy, reinforced by the threat of Dr Pusey and Canon Liddon to abandon their offices if it were carried. The bishop, moreover, took a prominent part in the Ritual controversy, opposing what he conceived to be Romanizing excess in ritual, as well as the endeavour of the opposite party to "put down Ritualism," as Mr Disraeli expressed it, by the operation of the civil law. In short, there was no subject affecting the Church or the moral well-being of

the people in which his influence was not felt, and in which his remarkable insight and acumen would not have done much service, could he have carried his colleagues with him. His incisive way of putting things earned for him the title of "the Militant Bishop," but, as he himself remarked in relation to this title, his efforts were ever for peace. Unfortunately for the Church, he was not elevated to the see of York until his energies were exhausted. He died on 5th May 1891, about four months after his appointment, leaving the Church the poorer for the loss of a statesman. His family were left impoverished by the heavy fees incident on his installation as archbishop. These were ultimately defrayed by a subscription—a tardy acknowledgment of a combination of gifts rare in the history of the English Church. His manifold activities, his capability as an administrator, his sound judgment, and his remarkable insight into the ecclesiastical problems of his time, may be best studied in the self-revelation of the man to his lifelong friend, Dr M'Donnell, formerly dean of Cashel, who published an account of the archbishop's life along with his correspondence. (J. J. L*.)

Magenta, a town of the province of Milan, Lombardy, Italy, situated in the midst of ricefields, 17 miles west of Milan by rail. It manufactures silks and matches, but is famous for the battle (1859) in which the allied French and Piedmontese defeated the Austrians. A monument was erected on the battlefield in 1862. Population, about 5500.

Maggiore, Lago, a lake of northern Italy and Switzerland, lying at the foot of the Lepontine Alps, due north from Novara. According to Marinelli, its area is 82 square miles, its altitude above sea-level 643 feet, and its maximum depth 1221 feet. Between midnight and morning it is usual for a northerly wind to blow, the Tramontana, whilst the Inverna, a southerly wind, prevails from noon until about four o'clock in the afternoon.

See O. MARINELLI, in *Geografia per Tutti* (1894); É. RITTER, in *Le Globe: Mémoires*, vol. vii. (1896); and, for a discussion of the hydrographic problems connected with the lake, G. FANTOLI, *Sul Régime Idraulico dei Laghi* (Milan, 1897).

Magic (including CONJURING and LEGERDEMAIN).—The article on White Magic in the earlier volumes of this work (ninth edition, vol. xv.) concludes with a description of Maskelyne's "box-trick"—a trick which others had only partially succeeded in imitating, and the secret of which has never been thoroughly elucidated. In dealing with the more recent history of magic and conjuring, we may conveniently take up the story at the point where the previous article leaves it.

Modern magic has given rise to many interesting developments, but none perhaps attracted a larger share of public attention than the legal battle in the last years of the century over the old box-trick, invented by Mr Maskelyne in 1860. The case had a special interest in England, from the fact that it was the only one in which a trick had ever occupied the attention of the House of Lords. The litigation arose in this way. Mr Maskelyne had been in the habit of offering a considerable reward to any one who could produce a correct imitation of his box-trick. The offer was a direct challenge to imitators, and was intended to show—as nothing else could have done—that the tricks sold and exhibited as "correct imitations" were not what they professed to be. Two amateur mechanics, having made or procured a box externally resembling Mr Maskelyne's, gave a private performance before a few friends, and then claimed the reward. Mr Maskelyne refused to pay, his contention being that hundreds of people had already escaped from locked and corded boxes resembling his in appearance. Indeed, it was

for that very reason that he had been compelled to make the offer. The claimants then brought an action to recover £500—the amount offered. Mr Maskelyne produced his box in court, and challenged the plaintiffs to expose the secret, contending that they could not possibly imitate correctly a trick of which they did not know the secret. Their point, however, was that they had nothing to do with the secret, and that a box-trick was not a trick-box. The jury, being unable to decide whether a mechanical trick is a piece of mechanism or the effect it produces, could not agree, and were discharged. In a second trial, the jury, after much deliberation, found for the plaintiffs. Mr Maskelyne appealed against the verdict. His appeal occupied the court for three days, and was dismissed. Finally he carried the case to the House of Lords, and lost it. The majority of the law lords, while fully admitting that the secret had never been discovered, were of opinion that the trick had been correctly "imitated." To people dealing with mechanical devices this decision is bound to appear not a little curious. A mechanical trick is a mechanical invention, and, when we have two absolutely different inventions, although they may produce more or less similar results, one is by no means an *imitation* of the other—to say nothing of a "correct imitation." Applied to inventions generally, such a ruling would produce disastrous results.

To those interested in magic, however, one effect of the litigation was to intensify the mystery surrounding the original box-trick. The whole matter has been publicly thrashed out. It has been learned that the trick, generally, consists of a movable panel fastened by a secret catch. Provided that the rope be not too severely knotted over the panel, the performer can escape; but otherwise failure is inevitable. Further, it is known that the original trick has never failed, even under the most severe tests, whereas the imitations have failed repeatedly. There can only be one reason for this—a great difference in the mechanical principles employed. What that difference may be can only be decided by future disclosures.

Like most forms of refined entertainment, magic appears to have kept well abreast of the times. Certainly, at no period of the world's history has it ever been so popular as at present. As a natural consequence, so many skilled exponents of the art have never before existed. Yet there is one respect in which at the present day magic shows no advance upon the records of earlier times. The one great peculiarity in connexion with magic, at every period, has been the limited number of those who prove themselves capable of originating magical effects. This peculiarity has never been more thoroughly emphasized than at present. Since the days of Robert Houdin, only two men have attained any remarkable degree of prominence—Mr Maskelyne and M. Buatier de Kolta. There are many who, as entertainers, are entitled to rank with the highest, but to those two only can prominence be justly given as originators. The only logical conclusion to be drawn is that to invent original illusions is a matter of no ordinary difficulty, and, indeed, all who have attempted work of that kind will admit that such is the case. When, however, an original principle has been invented, it may be utilized in producing many and apparently quite distinct effects. As an example of this, Maskelyne's "Cleopatra's Needle," invented in 1879, may be mentioned. The trick consisted of a piece of mechanism representing an exceedingly light model of the famous obelisk. So light was it, in fact, that it could easily be lifted with one hand. Upon an isolated stand, previously examined by the audience, a sheet of ordinary brown paper was laid, and on this the "needle" was placed. Thus during the performance communication with the obelisk

was obviously impossible. Yet from within it human beings emerged in a most startling manner. The secret consisted in the fact that the "needle" was capable of being lifted by invisible means, and from the outset contained two or three persons concealed within it. Notwithstanding the fact that this illusion was one of Mr Maskelyne's simplest devices, it puzzled even experts for a considerable time. When at last the secret leaked out, the principle was seized upon with avidity and utilized in a variety of ways—for example, by M. Buatier de Kolta in his beautiful illusion, "The Cocoon," first produced at the Egyptian Hall, London, in 1887. In this case de Kolta had the advantage of Mr Maskelyne's assistance in perfecting the mechanical details. De Kolta's smaller tricks have for years supplied the whole army of ordinary conjurers with novelties. In 1886, at the Eden Theatre, Paris, he introduced his famous illusion known as "The Vanishing Lady." This mystery, performed as he alone could perform it, was one of the most effective tricks ever exhibited. Hundreds of "imitations" were, of course, produced; but, like the imitations of Mr Maskelyne's box, they sink into insignificance when compared with the original; and in this case, unfortunately for the originator, the reputation of the original was speedily ruined by clumsy exponents, who only succeeded in exposing the principle. The effect produced by de Kolta was as follows:—Taking from his pocket what appeared to be an ordinary newspaper, folded, he opened it out and laid it upon the stage. Then a chair was shown, front and back, to the audience, and placed upon the paper. Madame de Kolta, in ordinary evening dress, then took her seat upon the chair, and a large piece of black silk was thrown over her, enveloping her from head to foot. Then de Kolta would shout, "I'll throw you in the air!"—or words to that effect—and to all appearance he grasped her round the waist, lifted her above his head, and she vanished, covering and all, at his finger-tips. The trick, as performed by imitators, is well known, and is described in many works upon conjuring, *e.g.*, in Hoffman's *Magic*.

Among the illusions depending for their effect upon sudden disappearance, perhaps the most inexplicable was that produced by Mr Maskelyne in 1891 under the appropriate title of "Oh!"—that being an expression frequently used by spectators upon witnessing the startling effect. In the illusion the performer whose disappearance was to be effected seated himself upon a raised couch, above which a kind of canopy was supported upon brass rods. From the canopy depended curtains capable of being raised or lowered. The right hand of the performer was strapped to one end of this couch, and the left hand was secured by means of a strap attached to one end of a stout cord. The other end of the cord, having been passed through a hole in the framework of the canopy, was securely held by a member of the audience. The curtains were then lowered to within 18 inches of the ground, and through an aperture in the front curtain the performer's right hand was passed. This hand, again, was held by a second member of the audience. Finally, a sheet of iron was placed beneath the couch, to prevent any possibility of the performer's escape being effected through a trap in the stage. Thus, with the performer's right hand in full view, his left drawn upwards by the cord attached to it, and a clear space below the couch, escape seemed impossible; yet, upon the word "Go!" the right hand disappeared, the cord became slack in the hands of the holder, the curtains were instantly raised, and the performer had vanished. The secret of this mystery, like many others associated with the Egyptian Hall, has been well preserved. Having a theatre to himself, and being sur-

rounded by trusty assistants, Mr Maskelyne possesses a great advantage. Those of his *confrères* who are obliged to perform at variety theatres and elsewhere must necessarily expose their secrets to stage hands. But, apart from this fact, some of Mr Maskelyne's effects are so elaborate in their mechanism that many weeks are occupied in making the stage arrangements. Such effects therefore would be quite impracticable for the purposes of the peripatetic illusionist.

In 1886 M. Buatier de Kolta, in conjunction with Mr Maskelyne, presented at the Egyptian Hall, London, a series of illusionary effects upon an entirely novel principle, to which they gave the name of "Black Magic." The main idea was based upon the fact—obvious when once it is pointed out—that visible form cannot exist in the absence of shadow or varying tint. In other words, we can only distinguish forms when they exhibit either variations in colour or shade. Absolute uniformity must, necessarily, mean invisibility. To bring about this uniformity, the entire stage was draped in black velvet, giving it the appearance of a dark and immensely deep cavern. There were no lights within it, though from the front it was brilliantly illuminated. Upon the stage, thus prepared, the most startling appearances and disappearances took place, within a few feet of the footlights. The illusions were produced by the simple method of covering anything to be concealed by screens of black velvet. These could be brought almost to the front of the stage, and yet would remain invisible; thus, in an instant, persons or articles would appear, apparently from space, or would disappear into it. The principle involved in the production of these illusions was adopted subsequently by many conjurers, and has served to produce an almost endless variety of effects.

The production of innumerable blossoms from a sheet of paper was undoubtedly the prettiest of M. Buatier de Kolta's smaller tricks. A small sheet of cartridge-paper is twisted into a cone, which is shown to be empty, but immediately artificial blossoms begin to pour out of it, until quite a bushel of them are piled up. Unfortunately for the inventor, the first time he introduced the trick at the Eden Theatre, Paris, one or two of the "blossoms" were carried by a draught of air into the auditorium. These were at once sold to a manufacturer of conjuring appliances, and within a few days de Kolta's "Spring Blossoms" were upon the market.

Another startling trick, by the same inventor, is "The Flying Cage." A live bird is imprisoned within a small cage, held between the performer's hands, when suddenly, by a quick movement of the arms, both bird and cage vanish. The cage simply collapses, and is drawn by a string up the coat-sleeve, the unfortunate bird being sometimes maimed, if not killed outright. The Society for the Prevention of Cruelty to Animals once took action in the matter, and sought to prevent the performance of the trick at one of the London music-halls; but the conjuror in this case invited the officials to witness a private demonstration, and was clever enough to convince them that there was no cruelty. Conjuring with animals has a great charm for young folk, and happily it is very seldom that a trick involves any cruelty whatever. The animals, as a rule, quickly become accustomed to the business, and appear thoroughly to understand what is required of them.

In recent years the mystery known as "Second Sight" has been vastly improved. The old system, invented by Pinetti in 1785, and brought to great perfection by Robert Houdin, has almost disappeared. It consisted of an elaborate code of signals, given by means of subtle variations in the questions put to the supposed clairvoyant;

the form in which the question was put conveying the appropriate answer. Now it is customary to avoid speech altogether. The information is conveyed by means of gesture or slight sounds at varying intervals. This business requires an enormous amount of practice, and an abnormal memory on the part of those who become expert.

But there are certain tricks of this class which require little or no skill and a very small amount of practice. These are generally introduced by impostors who claim or tacitly suggest the possession of supernatural powers. The following is a very familiar example of the kind of trick employed by such persons. The performers are usually a man and a woman. The man first appears, and informs the audience that he will shortly introduce a lady possessing extraordinary powers. Not only can she read the thoughts of any person whose mind is *en rapport* with hers, but also she can foretell the future, trace missing friends, discover lost property, &c. In order to display the lady's capabilities, he requests that any members of the audience who have questions they would like answered will write them secretly. For convenience in writing, slips of paper, pencils, and squares of thick millboard are passed round, the millboard squares being for use as writing-desks. The writers are particularly cautioned to allow no one to see what is written, but to fold up the papers and retain them in their own possession. Further, the writers are instructed that, when the clairvoyant appears, the thoughts of each must be kept intently fixed upon what he has written. The pencils and millboards are then collected, and the preparations being so far complete, other portions of the entertainment are proceeded with. Finally, as the last item in the programme, the clairvoyant is introduced. A handkerchief, upon which some liquid has been poured, is held over the lady's nose and mouth, and apparently she falls into a trance. Then she proceeds to describe the appearance of certain of the writers, the position they occupy in the room, and the nature of the questions they have written, giving to those questions more or less plausible answers. The trick never fails to produce the most profound astonishment, and by its means several persons have made rapid strides to fortune. But the whole business is an impudent imposture. Therefore it cannot be too often or too thoroughly exposed. It is accomplished as follows. Some of the millboards passed round for convenience in writing are built up of a number of thicknesses, fastened together at the edges only. Beneath the outer layer a sheet of carbon paper is concealed, so that the pressure of the pencil causes a reproduction in duplicate to be impressed upon an inner layer of cardboard. These prepared pads are handed round by attendants, who note the dress and appearance of the persons by whom the questions are written. That information, together with the prepared pads, is subsequently conveyed to the clairvoyant. She requires a certain amount of time in order to memorize the questions and the description of the writers; consequently she is not introduced to the audience until, say, an hour has elapsed. Of course, it would not be discreet to have all the millboards prepared. Many of them, perhaps the majority, are really what they appear to be; but, needless to say, the questions written upon these are never answered. It is carefully pointed out beforehand that the clairvoyant can only read the questions of those whose minds are in sympathy with hers. That statement, naturally, serves to account for her inability to read or answer questions written by those who have used the plain millboards.

In connexion with this trick a further imposture is carried out by inviting strangers to send, by post, any

questions they wish to have answered. Such an invitation appears to be quite straightforward and genuine, but those who are sufficiently credulous or sufficiently curious to respond to it lend themselves to the perpetration of an ingenious fraud. In reply to any such communication, the writer is informed that it is necessary for him to attend one of the public performances, and endeavour to bring his mind into harmony with that of the clairvoyant. Enclosed is a complimentary ticket entitling him to attend *any* performance he pleases. The procedure, then, is simply this. Each ticket bears a private mark, and a corresponding mark is put upon the letter written by the person to whom it is sent. When any marked ticket is presented, the attendant notes the dress and appearance of the visitor and the seat he occupies. That information is given to the clairvoyant, together with the ticket. She refers to the letter bearing the mark corresponding to the ticket, and ascertains what that particular visitor wishes to know. Thus to the public she appears to read and answer a question which has not been written down, but merely thought of by a total stranger. There are numerous methods of obtaining information by means similar to those already described. Sufficient, however, has been said to show that such devices are of the simplest, and require nothing more than a callous effrontery to carry them into effect. Of course, all kinds of mischances are bound to occur. But, when one is supposed to be dealing with undiscovered laws of nature, it does not require much ingenuity to wriggle out of any situation, however difficult.

In reference to that branch of conjuring known as "Legerdeman" or "Sleight-of-hand," which relies mainly upon dexterity of the fingers, for many years little advance was made. But recently some new sleights were introduced from America. These consist in an amplification of the method of concealing coins and cards at the back of the fingers. The principle has received the incongruous title of "back-palming." By means of this method both back and front of the hand alternately can be shown empty, while, notwithstanding its apparent emptiness, the hand nevertheless conceals a coin or card. The first and fourth fingers are caused to act as pivots, upon which the concealed articles are turned from front to back, and *vice versa*, the turning being performed by the second and third fingers. The movement is very rapid, and is accomplished in the act of turning over the hand to show the two sides alternately. The sleight requires an enormous amount of practice. It has been brought to the highest state of perfection by Herr Valadon.

In all ages a very popular magical effect has been the apparent floating of a person in empty space. An endless variety of ingenious apparatus has been invented for the purpose of producing such effects, and the present article would be incomplete without some reference to one or two of the more modern examples. A very pretty illusion of this kind is that originally produced under the title of "Astarte." A lady is brought forward, and after making her bow to the audience she retires to the back of the stage, the whole of which is draped with black velvet and kept in deep shadow. There she is caused to rise in the air, to move from side to side, to advance and retire, and to revolve in all directions. The secret consists in an iron lever, covered with velvet to match the background, and therefore invisible to the audience. This lever is passed through an opening in the back curtain and attached to a socket upon the metal girdle worn by the performer. The girdle consists of two rings, one inside the other, the inner one being capable of turning about its axis. By means of this main lever and a spindle passing through it and gearing into the inner

ring of the girdle, the various movements are produced. A hoop is passed over the performer with a view to demonstrate her complete isolation, but the audience is not allowed to examine it. It has a spring joint which allows it to pass the supporting lever. Among illusions of this class there is probably none that will bear comparison with the "levitation" mystery produced by Mr Maskelyne. A performer, in a recumbent position, is caused to rise several feet from the stage, and to remain suspended in space while an intensely brilliant light is thrown upon him, illuminating the entire surroundings. Persons walk completely round him, and a solid steel hoop, examined by the audience, is passed over him, backwards and forwards, to prove the absence of any tangible connexion. The most skilled experts have failed to give any adequate explanation of this mystery, of which the secret has been well preserved.

(G. FA. ; J. N. M.)

Magliani, Agostino (1824–1891), Italian politician and financier, was born at Laurino, Salerno, in 1824. Entering the Neapolitan financial administration,

he showed such aptitude as to be selected by Sella in 1862 for the post of secretary-general of the Italian Ministry of Finance. Shortly after the advent of the Left he was created senator, and appointed by Depretis Minister of Finance (1877), a position which he held, in spite of attacks, for eleven years. More than any other Italian politician, Magliani represented the "democratic finance" of the Left, arranging for the repeal of the grist tax, reducing the price of salt, and contracting a foreign loan for the abolition of the forced paper currency; but at the same time he seriously burdened the lower classes by increasing indirect taxation to the extent of £12,000,000 per annum, and inaugurating a policy of exaggerated protection. The abolition of the forced currency gained for him temporary popularity; but as the metallic currency gradually proved unequal to the strain of the financial situation, his prestige declined, and he was obliged to resign in December 1888. Unduly optimistic in temperament and lax in administration, he contributed to create the desperate financial position of 1888–1893, but died on 21st February 1891, before realizing the worst consequences of his policy.

(H. W. S.)

MAGNETISM.

THE present article contains a short account of the general experimental work in magnetism which has been carried out since the publication of the important treatise in the ninth edition of the *Encyclopædia Britannica*, vol. xv. pp. 219–276. In an introductory section a few elementary formulæ relating to matters of fundamental importance are collected, and definitions are given of the principal terms in common use. Repetition has, as far as possible, been avoided, and this article must be regarded as merely supplementary to the former one. Some special branches of the subject are dealt with in separate articles under the headings MEASURING INSTRUMENTS, ELECTRIC; ELECTROMAGNETS; MAGNETO-OPTICS; and MAGNETISM, TERRESTRIAL. These should be consulted by the reader who desires to acquaint himself with recent advances in the directions indicated.

TERMINOLOGY AND ELEMENTARY PRINCIPLES.

In what follows, the C.G.S. electromagnetic system of units will be generally adopted, and, unless otherwise stated, magnetic substances will be assumed to be isotropic.

Magnetic Classification of Substances.—According to the discovery of Faraday, all substances are either attracted or repelled by the pole of a sufficiently powerful magnet. The metals iron, nickel, and cobalt, together with some of their alloys and compounds, exhibit the phenomenon of attraction in a particularly striking manner. These form a class by themselves, and are spoken of as *ferromagnetic*, or, when confusion is not likely to arise, simply as *magnetic* substances. Those bodies which are attracted, but in a very much less degree, are termed *paramagnetic*; while those which exhibit repulsion are known as *diamagnetic*.

Unit Magnetic Pole.—A pole of unit strength is that which acts on an equal pole at a distance of one centimetre with a force of one dyne. A pole which points north is reckoned positive, one which points south negative. If m_1 and m_2 are the strength of two poles, d the distance between them expressed in centimetres, and f the force in dynes, then $f = m_1 m_2 / d^2$. The poles at the ends of an infinitely thin magnet, or *magnetic filament*, would act as definite centres of force. An actual magnet may be regarded as a bundle of magnetic filaments, and those portions of the surface of the magnet where the magnetic filaments terminate, and so-called "free magnetism" appears, may be conveniently called poles or polar regions.

Magnetic Field.—The strength or intensity of a magnetic field at any point is measured by the force in dynes which a unit pole will experience when placed at that point, the direction of the field being the direction in which a positive pole is urged. The

field strength at any point is also called the *magnetic force* at that point; it is denoted by H , or, when it is desired to draw attention to the fact that it is a vector or directed quantity, by the block letter H or the German character \mathfrak{H} .¹ A *line of force* is a line drawn through a magnetic field in the direction of the force at each point through which it passes. A *uniform magnetic field* is one in which H has everywhere the same value and the same direction, the lines of force being therefore straight and parallel. A magnetic field is produced either by a conductor carrying an electric current or by the pole of a magnet. The direction of the magnetic field due to a long straight wire in which a current is flowing is at every point at right angles to the plane passing through it and through the wire. Its strength at any point distant r centimetres from the wire is

$$H = 2i/r,$$

i being the current in C.G.S. units.² The lines of force are evidently circles concentric with the wire and in planes at right angles to it. The field at the centre of a circular conductor of radius r through which a current is passing is

$$H = 2\pi i/r,$$

the direction of the field being along the axis. The field strength in the interior of a long uniformly wound coil containing n turns of wire and having a length of l centimetres is (except near the ends)

$$H = 4\pi in/l.$$

In the middle portion of the coil the strength of the field is very nearly uniform, but towards the ends it diminishes, and at the ends themselves is reduced to one-half. The direction of the field is parallel to the axis of the coil, and is related to the direction of the current circulating through the wire in the same manner as the thrust of a corkscrew is related to its rotation. If the coil has the form of an endless ring of mean radius r , the length will be $2\pi r$, and the field inside the coil may be expressed as

$$H = 2\pi i/r.$$

The uniformity of the field is not in this case disturbed by the influence of ends, but its strength at any point varies inversely as the distance from the axis of the ring. When, therefore, sensible uniformity is desired, the radius of the ring should be large in relation to that of the convolutions, or the ring should have the form of a short cylinder with thin walls. The strongest magnetic fields employed for experimental purposes are obtained by the use of electromagnets. For many experiments the field due to the earth's magnetism is sufficient; this is practically quite uniform throughout considerable spaces, but its total

¹ Maxwell employed German characters to denote vector quantities. J. A. Fleming first recommended the use of block letters, as being more convenient both to printers and to readers. In the article MAGNETISM (*Ency. Brit.* 9th ed.) Old English characters are used.

² The C.G.S. unit of current = 10 amperes.

intensity is less than half a unit. Magnetic force is sometimes, and perhaps more suitably, termed *magnetic intensity*; it corresponds to the intensity of gravity g in the theory of heavy bodies (see Maxwell, *Electricity and Magnetism*, § 12 and § 68, footnote).

Magnetic Induction or Magnetic Flux.—When magnetic force acts on any medium, whether magnetic or diamagnetic or neutral, it produces within it a phenomenon of the nature of a flux called *magnetic induction* (Maxwell, *loc. cit.* § 428). Magnetic induction, like other fluxes, such as electric, thermal, or fluid currents, is defined with reference to an area; it satisfies the same conditions of continuity as the electric current docs, and in isotropic media it depends on the magnetic force just as the electric current depends on the electromotive force. The magnitude of the flux produced by a given magnetic force differs in different media. In a uniform magnetic field of unit intensity, formed in empty space, the induction or magnetic flux across an area of 1 square centimetre normal to the direction of the field is arbitrarily taken as the unit of induction. Hence, if the induction per square centimetre at any point is denoted by B (or by \mathfrak{B} or \mathfrak{B} when the vector quality is to be attended to), then in empty space B is numerically equal to H ; moreover, in isotropic media both have the same direction, and for these reasons it is often said that in empty space (and practically in air) B and H are identical. Their numerical equality is, however, a mere accident, depending upon the capricious selection of a definition by the framers of the C.G.S. electromagnetic system of units (see ELECTRICITY, § iv, *Electric Units*). The magnetic flux per square centimetre at any point (B , \mathfrak{B} , or \mathfrak{B}) is briefly called the *induction*, or, especially by electrical engineers, the *flux-density*. The direction of magnetic induction may be indicated by *lines of induction*; a line of induction is always a closed curve. Lines of induction drawn through every point in the contour of a small surface form a re-entrant tube bounded by lines of induction; such a tube is called a *tube of induction*. The cross-section of a tube of induction may vary in different parts, but the total induction across any section is everywhere exactly the same. A special meaning has been assigned to the term "lines of induction." Suppose the whole space in which induction is taking place to be divided up into *unit tubes*, such that the surface integral of the induction over any cross-section of a tube is equal to unity, and along the axis of each tube let a line of induction be drawn. These axial lines constitute the system of lines of induction which are so often referred to in the specification of a field. Where the induction is high, the lines will be crowded together; where it is weak, they will be widely separated, the number per square centimetre crossing a normal surface at any point being always equal to the numerical value of B . The induction may therefore be specified as B lines per square centimetre. The direction of the induction is also of course indicated by the direction of the lines, which thus serve to map out space in a convenient manner. Lines of induction are frequently but inaccurately spoken of as lines of force.

Magnetic Moment and Magnetization.—The moment of a uniformly and longitudinally magnetized bar magnet is the product of its length into the strength of one of its poles. The *intensity of magnetization*, or, more shortly, the *magnetization* of a uniformly magnetized body, is defined as the magnetic moment per unit of volume (1 cubic centimetre), and is denoted by I , \mathfrak{I} , or \mathfrak{I} . When induction or magnetic flux takes place in a ferromagnetic metal, the metal becomes magnetized, but the magnetization at any point is proportional not to B , but to $B - H$. If the C.G.S. electromagnetic system of units is adopted, the factor of proportionality will be $1/4\pi$, so that

$$\begin{aligned} I &= (B - H)/4\pi, \\ B &= H + 4\pi I. \end{aligned}$$

or

Unless the path of the induction is entirely inside the metal, free magnetic poles are developed at those parts of the metal where induction enters and leaves, the polarity being south at the entry and north at the exit of the flux. These free poles produce a magnetic field which is coexistent with that arising from other sources. The *resultant magnetic field*, therefore, is compounded of two fields, the one being due to the poles, and the other to the external causes which would be operative in the absence of the magnetized metal. The intensity (at any point) of the field due to the magnetization may be denoted by H_i , that of the external field by H_0 , and that of the resultant field by H . In certain cases, as, for instance, in an iron ring wrapped uniformly round with a coil of wire through which a current is passing, the induction is entirely within the metal; there are, consequently, no free poles, and the ring, though magnetized, constitutes a poleless magnet. Magnetization is usually regarded as the direct effect of magnetic force, which is therefore often termed the *magnetizing force*.

Permeability and Susceptibility.—The ratio B/H is called the *permeability* of the medium in which the induction is taking

place, and is denoted by μ . The ratio I/H is called the *susceptibility* of the magnetized substance, and is denoted by κ . Hence

$$B = \mu H \text{ and } I = \kappa H.$$

Also

$$\mu = \frac{B}{H} = \frac{H + 4\pi I}{H} = 1 + 4\pi\kappa,$$

and

$$\kappa = \frac{\mu - 1}{4\pi}.$$

Since in empty space B has been assumed to be numerically equal to H , it follows that the permeability of a vacuum is equal to 1. The permeability of most material substances differs very slightly from unity, being greater in paramagnetic and less in diamagnetic substances. In the case of the ferromagnetic metals and some of their alloys and compounds, the permeability has generally a much higher value. Moreover, it is not constant, being an apparently arbitrary function of H or of B ; in the same specimen its value may, under different conditions, vary from less than 2 to upwards of 5000. The magnetic susceptibility κ expresses the numerical relation of the magnetization to the magnetizing force. From the equation $\kappa = (\mu - 1)/4\pi$, it follows that the magnetic susceptibility of a vacuum (where $\mu = 1$) is 0, that of a diamagnetic substance (where $\mu < 1$) has a negative value, while the susceptibility of paramagnetic and ferromagnetic substances (for which $\mu > 1$) is positive. No substance has yet been discovered having a negative susceptibility sufficiently great to render the permeability ($= 1 + 4\pi\kappa$) negative.

Hysteresis, Coercive Force, Retentiveness.—It is found that when a piece of ferromagnetic metal, such as iron, is subjected to a magnetic field of changing intensity, the changes which take place in the induced magnetization of the iron exhibit a tendency to lag behind those which occur in the intensity of the field—a phenomenon to which Ewing (*Phil. Trans.* vol. clxxvi. p. 524) has given the name of *hysteresis* (from *ὑστερέω*, to lag behind). Thus it happens that there is no definite relation between the magnetization of a piece of metal which has been previously magnetized and the strength of the field in which it is placed. Much depends upon its antecedent magnetic condition, and indeed upon its whole magnetic history. A well-known example of hysteresis is presented by the case of permanent magnets. If a bar of hard steel is placed in a strong magnetic field, a certain intensity of magnetization is induced in the bar; but when the strength of the field is afterwards reduced to zero, the magnetization does not entirely disappear. That portion which is permanently retained, and which may amount to considerably more than one-half, is called the *residual magnetization*. The ratio of the residual magnetization to its previous maximum value measures the *retentiveness* of the metal.¹ Steel which is well suited for the construction of permanent magnets is said to possess great "coercive force." To this term, which had long been used in a loose and indefinite manner, Hopkinson supplied a precise meaning (*Phil. Trans.* vol. clxxvi. p. 460). The *coercive force* of a material is that reversed magnetic force which, while it is acting, just suffices to reduce the residual induction to nothing after the material has been temporarily submitted to any great magnetizing force. A metal which has great retentiveness may at the same time have small coercive force, and it is the latter quality which is of chief importance in permanent magnets.

Demagnetizing Force.—It has already been mentioned that when a ferromagnetic body is placed in a magnetic field, the resultant magnetic force H , at a point within the body, is compounded of the force H_0 , due to the external field, and of another force, H_i , arising from the induced magnetization of the body. Since H_i generally tends to oppose the external force, thus making H less than H_0 , it may be called the *demagnetizing force*. Except in a few special cases, when a uniform external field produces uniform magnetization, the value of the demagnetizing force cannot be calculated, and an exact determination of the actual magnetic force within the body is therefore impossible. An important instance in which the calculation can be made is that of an elongated ellipsoid of revolution placed in a uniform field H_0 , with its axis of revolution parallel to the lines of force. The magnetization at any point inside the ellipsoid will then be

$$I = \frac{\kappa H_0}{1 + \kappa N}$$

where

$$N = 4\pi \left(\frac{1}{e^2} - 1 \right) \left(\frac{1}{2e} \log \frac{1+e}{1-e} - 1 \right),$$

e being the eccentricity (see *Ency. Brit.* vol. xv. pp. 246, 232). Since $I = \kappa H$, we have

$$\begin{aligned} \kappa H + \kappa NI &= \kappa H_0, \\ H &= H_0 - NI, \end{aligned}$$

or

NI being the demagnetizing force H_i . N may be called, after du Bois (*Magnetic Circuit*, p. 33), the *demagnetizing factor*, and

¹ Hopkinson specified the retentiveness by the numerical value of the "residual induction" ($= 4\pi I$).

the ratio of the length of the ellipsoid $2c$ to its equatorial diameter $2a$ ($=c/a$), the *dimensional ratio*, denoted by the symbol m .

Since
$$e = \sqrt{1 - \frac{a^2}{c^2}} = \sqrt{1 - \frac{1}{m^2}},$$

the above expression for N may be written

$$N = \frac{4\pi}{m^2 - 1} \left(\frac{m}{2\sqrt{m^2 - 1}} \log \frac{m + \sqrt{m^2 - 1}}{m - \sqrt{m^2 - 1}} - 1 \right)$$

$$= \frac{4\pi}{m^2 - 1} \left\{ \frac{m}{\sqrt{m^2 - 1}} \log \left(m + \sqrt{m^2 - 1} \right) - 1 \right\},$$

from which the value of N for a given dimensional ratio can be calculated. When the ellipsoid is so much elongated that 1 is negligible in relation to m^2 , the expression approximates to the simpler form

$$N = \frac{4\pi}{m^2} (\log 2m - 1).$$

The demagnetizing force inside a cylindrical rod placed longitudinally in a uniform field H_0 is not uniform, being greatest at the ends and least in the middle part. Denoting its mean value by \bar{H}_z , and that of the demagnetizing factor by \bar{N} , we have

$$H = H_0 - \bar{H}_z = H_0 - \bar{N}I.$$

Du Bois has shown that when the dimensional ratio m ($=$ length/diameter) exceeds 100, $\bar{N}m^2 = \text{constant} = 45$, and hence for long thin rods

$$\bar{N} = 45/m^2.$$

From an analysis of a number of experiments made with rods of different dimensions, du Bois has deduced the corresponding mean demagnetizing factors. These, together with values of $m^2\bar{N}$ for cylindrical rods, and of N and m^2N for ellipsoids of revolution, are given in the following very useful table (*loc. cit.* p. 41):—

Demagnetizing Factors.

m.	Cylinder.		Ellipsoid.	
	\bar{N} .	$m^2\bar{N}$.	N.	m^2N .

In the middle part of a rod which has a length of 400 or 500 diameters the effect of the ends is insensible; but for many experiments the condition of endlessness may be best secured by giving the metal the shape of a ring of uniform section, the magnetic field being produced by an electric current through a coil of wire evenly wound round the ring. In such cases $H_z = 0$ and $H = H_0$.

The residual magnetization I_r retained by a bar of ferromagnetic metal after it has been removed from the influence of an external field produces a demagnetizing force $\bar{N}I_r$, which is greater the smaller the dimensional ratio. Hence the difficulty of imparting any considerable permanent magnetization to a short thick bar not possessed of great coercive force. The magnetization retained by a long thin rod, even when its coercive force is small, is sometimes little less than that which was produced by the direct action of the field.

Demagnetization by Reversals.—In the course of an experiment it is often desired to eliminate the effects of previous magnetization, and, as far as possible, wipe out the magnetic history of a specimen. In order to attain this result it was formerly the practice to raise the metal to a bright red heat, and allow it to

cool while carefully guarded from magnetic influence. This operation, besides being very troublesome, was open to the objection that it was almost sure to produce a material but uncertain change in the physical constitution of the metal, so that, in fact, the results of experiments made before and after the treatment were not comparable. Ewing introduced the method (*Phil. Trans.* vol. clxxvi. p. 539) of demagnetizing a specimen by subjecting it to a succession of magnetic forces which alternated in direction and gradually diminished in strength from a high value to zero. By means of a simple arrangement, which will be described farther on, this process can be carried out in a few seconds, and the metal can be brought as often as desired to a definite condition, which, if not quite identical with the virgin state, at least closely approximates to it.

The laws of the *magnetic circuit* are discussed under the heading ELECTROMAGNET.

MAGNETIC MEASUREMENTS.

Measurement of Magnetization and Induction.—The magnetic condition assumed by a piece of ferromagnetic metal in different circumstances is determinable by various modes of experiment which may be classed as magnetometric, ballistic, and traction methods. When either the magnetization I or the induction B corresponding to a given magnetizing force H is known, the other may be found by means of the formula $B = 4\pi I + H$.

Magnetometric Methods.—Intensity of magnetization is most directly measured by observing the action which a magnetized body, generally a long straight rod, exerts upon a small magnetic needle placed near it. The magnetic needle may be cemented horizontally across the back of a little plane or concave mirror, about $\frac{1}{4}$ or $\frac{3}{8}$ inch in diameter, which is suspended by a single fibre of unspun silk; this arrangement, when enclosed in a case with a glazed front to protect it from currents of air, constitutes a simple but efficient magnetometer. Deflections of the suspended needle are indicated by the movement of a narrow beam of light which the mirror reflects from a lamp and focusses upon a graduated cardboard scale placed at a distance of a few feet; the angular deflection of the beam of light is, of course, twice that of the needle. The suspended needle is, in the absence of disturbing causes, directed solely by the horizontal component of the earth's field of magnetic force H_z , and therefore sets itself approximately north and south. The magnetized body which is to be tested should be placed in such a position that the force H_r due to its poles may, at the spot occupied by the suspended needle, act in a direction at right angles to that due to the earth—that is, east and west. The direction of the resultant field of force will then make, with that of H_z , an angle θ , such that $H_r/H_z = \tan \theta$, and the suspended needle will be deflected through the same angle. We have therefore

$$H_r = H_z \tan \theta.$$

The angle θ is indicated by the position of the spot of light upon the scale, and the horizontal intensity of the earth's field H_z is known; thus we can at once determine the value of H_r , from which the magnetization I of the body under test may be calculated.

In order to fulfil the requirement that the field which a magnetized rod produces at the magnetometer shall be at right angles to that of the earth, the rod may be conveniently placed in any one of three different positions with regard to the suspended needle.

(1) The rod is set in a horizontal position level with the suspended needle, its axis being in a line which is perpendicular to the magnetic meridian, and which passes through the centre of suspension

Fig. 1.

This is called the "end-on" position, and is indicated in Fig. 1. AB is the rod and C the middle point of its axis; NS is the magnetometer needle; AM bisects the

undeflected needle NS at right angles. Let $2l$ = the length of the rod (or, more accurately, the distance between its poles), v = its volume, m and $-m$ the strength of its poles, and let d = the distance CM. For most ordinary purposes the length of the needle may be assumed to be negligible in comparison with the distance between the needle and the rod. We then have approximately for the field at M due to the rod

$$H_r = \frac{m}{(d-l)^2} - \frac{m}{(d+l)^2} = m \frac{4dl}{(d^2-l^2)^2}$$

Therefore

$$2ml = \frac{(d^2-l^2)^2 H}{2d} = \frac{(d^2-l^2)^2 H_x \tan \theta}{2d}$$

And

$$I = \frac{2ml}{v} = \frac{(d^2-l^2)^2 H_x \tan \theta}{2dv}$$

whence we can find the values of I which correspond to different angles of deflection.

(2) The rod may be placed horizontally east and west in such a position that the direction of the undeflected suspended needle bisects it at right angles. This is known as the "broadside-on" position, and is represented in Fig. 2. Let the distance of each pole of the rod AB from the centre of the magnetometer needle = d . Then, since H_r , the force at M due to m and $-m$, is the resultant of $\frac{m}{d^2}$ and $-\frac{m}{d^2}$ we have

$$\frac{H_r}{m} = \frac{2l}{d^2}$$

or

$$H = \frac{2ml}{d^2}$$

the direction being parallel to AB.

And

$$I = \frac{d^3 H_r}{v} = \frac{d^3 H_x \tan \theta}{v}$$

(3) In the third position the test rod is placed vertically with one of its poles at the level of the magnetometer needle, and in the

Fig. 2.

Fig. 3.

line drawn perpendicularly to the undeflected needle from its centre of suspension. The arrangement is shown in Fig. 3, where AB is the vertical rod and M indicates the position of the magnetometer needle, which is supposed to be perpendicular to the plane of the paper. Denoting the distance AM by d_1 , BM by d_2 , and AB by l , we have for the force at M due to the magnetism of the rod

$$H_r = \frac{m}{d_1^2} - \text{horizontal component of } \frac{m}{d_2^2} = m \left(\frac{1}{d_1^2} - \frac{d_1}{d_2^3} \right)$$

Therefore

$$m = \frac{H_r}{\frac{1}{d_1^2} - \frac{d_1}{d_2^3}} = \frac{d_1^2 H_r}{1 - \left(\frac{d_1}{d_2}\right)^3} \tan \theta,$$

and

$$I = \frac{ld_1^2 H_r}{v \left\{ 1 - \left(\frac{d_1}{d_2}\right)^3 \right\}} \tan \theta.$$

This last method of arrangement is called by Ewing the "one-pole" method, because the magnetometer deflection is mainly caused by the upper pole of the rod (*Magnetic Induction*, p. 40). For experiments with long thin rods or wires it has an advantage over the other arrangements in that the position of the poles need not be

known with great accuracy, a small upward or downward displacement having little effect upon the magnetometer deflection. On the other hand, a vertically-placed rod is subject to the inconvenience that it is influenced by the earth's magnetic field, which is not the case when the rod is horizontal and at right angles to the magnetic meridian. This extraneous influence may, however, be allowed for, or it may preferably be eliminated by surrounding the rod with a coil of wire carrying a current such as will produce in the interior a magnetic field equal and opposite to the vertical component of the earth's field.

If the card-board scale upon which the beam of light is reflected by the magnetometer mirror is a flat one, the deflections as indicated by the movement of the spot of light are related to the actual deflections of the needle in the ratio of $\tan 2\theta$ to θ . Since θ is always small, sufficiently accurate results may generally be obtained, and much trouble saved, if we assume that $\tan 2\theta = 2 \tan \theta$. If the distance of the mirror from the scale is equal to n scale divisions, and if a deflection θ of the needle causes the reflected spot of light to move over s scale divisions, we shall have

$$\begin{aligned} s/n &= \tan 2\theta \text{ exactly,} \\ s/2n &= \tan \theta \text{ approximately.} \end{aligned}$$

We may therefore generally substitute $s/2n$ for $\tan \theta$ in the various expressions which have been given for I.

Of the three methods which have been described, the first two are generally the most suitable for determining the moment or the magnetization of a permanent magnet, and the last for studying the changes which occur in the magnetization of a long rod or wire when subjected to various external magnetic forces, or, in other words, for determining the relation of I to H. A plan of the apparatus as arranged by Ewing for the latter purpose is shown diagrammatically in Fig. 4. The card-board scale SS is placed

Fig. 4.

above a wooden screen, having in it a narrow vertical slit which permits a beam of light from the lamp L to reach the mirror of the magnetometer M, whence it is reflected upon the scale. A is the upper end of a glass tube, half a metre or so in length, which is clamped in a vertical position behind the magnetometer. The tube is wound over its whole length with two separate coils of insulated wire, the one being outside the other. The inner coil is supplied, through the intervening apparatus, with current from the battery of secondary cells B_1 ; this produces the desired magnetic field inside the tube. The outer coil derives current, through an adjustable resistance R, from a constant cell B_2 ; its object is to produce inside the tube a magnetic field equal and opposite to that due to the earth's magnetism. C is a "compensating coil" consisting of a few turns of wire through which the magnetizing current passes; it serves to neutralize the effect produced upon the magnetometer by the magnetizing coil, and its distance from the magnetometer is so adjusted that when the circuit is closed, no ferromagnetic metal being inside the magnetizing coil, the magnetometer needle undergoes no deflection. K is a commutator for reversing the direction of the magnetizing current, and G a galvanometer for measuring it. The strength of the magnetizing current is regulated by adjusting the position of the sliding contact E upon the resistance DF. In Ewing's experiments the resistance employed was a liquid one, but except when variations of the current are required to be absolutely continuous, it is less troublesome to use a spiral of bare German silver wire wound rather closely upon a long insulating cylinder. The current increases to a maximum as E approaches F, and diminishes to almost nothing when E is brought up to D; it can be completely interrupted by means of the switch H.

The specimen upon which an experiment is to be made generally consists of a wire having a "dimensional ratio" of at least 300 or 400; its length should be rather less than that of the magnetizing coil, in order that the field H_0 , to which it is subjected, may be approximately uniform from end to end. The wire is supported inside the glass tube A with its upper pole at the same height as the magnetometer needle. Various currents are then passed through the magnetizing coil, the galvanometer readings and the simultaneous magnetometer deflections being noted. From the former

we deduce H_0 , and from the latter the corresponding value of I , using the formulæ $H_0 = 4\pi in/l$ and

$$I = \frac{d_1^2 H_z}{2n\pi r^2 \left\{ 1 - \left(\frac{d_1}{d_0} \right)^3 \right\}} \times s,$$

where s is the deflection in scale-divisions, n the distance in scale-divisions between the scale and the mirror, and r the radius of the wire.

The curve, Fig. 5, shows the result of a typical experiment made upon a piece of soft iron (Ewing, *Phil. Trans.* vol. clxxvi. plate 59), the magnetizing field H_0 being first gradually increased and then diminished to zero. When the length of the wire exceeds 400 diameters, or thereabouts, H_0 may generally be considered as

Fig. 5.

equivalent to H , the actual strength of the field as modified by the magnetization of the wire; but if great accuracy is desired, the value of $H_z (=NI)$ may be found by the help of du Bois's table and subtracted from H_0 . For a dimensional ratio of 400, $N = 0.00028$, and therefore $H = H_0 - 0.00028 I$. This correction may be indicated in the diagram by a straight line drawn from 0 through the point at which the line of $I = 1000$ intersects that of $H = 0.28$ (Rayleigh, *Phil. Mag.* vol. xxii. p. 175), the true value of H for any point on the curve being that measured from the sloping line instead of from the vertical axis. The effect of the ends of the wire is, as Ewing remarks, to shear the diagram in the horizontal direction through the angle which the sloping line makes with the vertical.

Since the induction B is equal to $H + 4\pi I$, it is easy from the results of experiments such as that just described to deduce the relation between B and H ; a curve indicating such relation is called a curve of induction. The general character of curves of magnetization and of induction will be discussed later. A notable feature in both classes of curves is that, owing to hysteresis, the ascending and descending limbs do not coincide, but follow very different courses. If it is desired to annihilate the hysteretic effects of previous magnetization and restore the metal to its original condition, it may be demagnetized by reversals. This is effected by slowly moving the sliding contact E (Fig. 4) from F to D , while at the same time the commutator K is rapidly worked, a series of alternating currents of gradually diminishing strength being thus caused to pass through the magnetizing coil.

Several pieces of apparatus in which a magnetometer is employed have been devised for comparing the magnetic quality of a sample with that of a standard iron rod by a zero method analogous to that of the Wheatstone bridge. An excellent instrument of the class is Ewing's "permeability bridge," a description of which will be found under ELECTROMAGNET.

Ballistic Methods.—The so-called "ballistic" method of measuring induction is based upon the fact that a change of the induction through a closed linear conductor sets up in the conductor an electromotive force which is proportional to the rate of change. (See *Ency. Brit.*, ELECTRICITY, vol. viii. p. 75; and MAGNETISM, vol. xv. p. 240.) If the conductor consists of a coil of wire the ends of which are connected with a suitable galvanometer, the integral electromotive force due to a sudden increase or decrease of the induction through the coil displaces in the circuit a quantity of electricity $Q = \delta Bns/R$, where δB is the increment or decrement of induction per square centimetre, s is the area of the coil, n the number of turns of wire, and R the resistance of the circuit. Under the influence of the transient current, the galvanometer needle undergoes a momentary deflection, or "throw,"

which is proportional to Q , and therefore to δB , and thus, if we know the deflection produced by the discharge through the galvanometer of a given quantity of electricity, we have the means of determining the value of δB .

The galvanometer which is used for ballistic observations should have a somewhat heavy needle with a period of vibration of not less than five seconds, so that the transient current may have ceased before the swing has well begun; an instrument of the d'Arsonval form is recommended, not only because it is unaffected by outside magnetic influence, but also because the moving part can be instantly brought to rest by means of a short-circuit key, thus effecting a great saving of time when a series of observations is being made. In practice it is usual to standardize or "calibrate" the galvanometer by causing a known change of induction to take place within a standard coil connected with it, and noting the corresponding deflection on the galvanometer scale. Let s be the area of a single turn of the standard coil, n the number of its turns, and r the resistance of the circuit of which the coil forms part; and let S , N , and R be the corresponding constants for a coil which is to be used in an experiment. Then if a known change of induction δB_s inside the standard coil is found to cause a throw of d scale-divisions, any change of induction δB through the experimental coil will be numerically equal to the corresponding throw D multiplied by $snRB_s/SNrd$. For a series of experiments made with the same coil this fraction is constant, and we may write $\delta B = kD$. Rowland and others (*Ency. Brit.* vol. xv. p. 255) have used an earth coil for calibrating the galvanometer, a known change of induction through the coil being produced by turning it over in the earth's magnetic field, but for several reasons it is preferable to employ an electric current as the source of a known induction. A primary coil of length l , having n turns, is wound upon a cylinder made of non-conducting and non-magnetic material, and upon the middle of the primary a secondary or induction coil is closely fitted. When a current of strength i is suddenly interrupted in the primary, the increment of induction through the secondary is sensibly equal to $4\pi in/l$ units. All the data required for standardizing the galvanometer can in this way be determined with accuracy.

The ballistic method is largely employed for determining the relation of induction to magnetizing force in samples of the iron and steel used in the manufacture of electrical machinery, and especially for the observation of hysteresis effects. The sample may have the form of a closed ring, upon which are wound the induction coil and another coil for taking the magnetizing current; or it may consist of a long straight rod or wire which can be slipped into a magnetizing coil such as is used in magnetometric experiments, the induction coil being wound upon the middle of the wire. With these arrangements there is no demagnetizing force to be considered, for the ring has not any ends to produce one, and the force due to the ends of a rod 400 or 500 diameters in length is quite insensible at the middle portion; H therefore is equal to H_0 .

Induction and Hysteresis Curves.—Some typical induction curves, copied from a paper by Ewing (*Proc. Inst. C.E.* vol. cxxvi.), are given in Figs. 6, 7, and 8. Fig. 6 shows the relation of B to H in a specimen which has never before been magnetized. The experiment may be made in two different ways: (1) the magnetizing current is increased by a series of sudden steps, each of which produces a ballistic throw, the value of B after any one throw being proportional to the sum of that and all the previous throws; (2) the magnetizing current having been brought to any desired value, is suddenly reversed,

and the observed throw taken as measuring twice the actual induction. Fig. 7 shows the nature of the course taken by the curve when the magnetizing current, after having been raised to the value corresponding to the point *a*, is diminished by steps until it is nothing, and then gradually increased in the reverse direction. The downward course of the curve is, owing to hysteresis, strikingly different from its upward course, and when the magnetizing

Fig. 6.

Fig. 7.

Fig. 8.

force has been reduced to zero, there is still remaining an induction of 7500 units. If the operation is again reversed, the upward course will be nearly, but not exactly, of the form shown by the line *d e a*, Fig. 8. After a few repetitions of the reversal, the process becomes strictly cyclic, the upward and downward curves always following with precision the paths indicated in the figure. In order to establish the cyclic condition, it is sufficient to apply alternately the greatest positive and negative forces employed in the test (greatest *H* = about ± 5 C.G.S. units in the case illustrated in the figure), an operation which is performed by simply reversing the direction of the maximum magnetizing current a few times.

The closed figure *a c d e a* is variously called a *hysteresis curve* or *diagram* or *loop*. The area $\int HdB$ enclosed by it represents the work done in carrying a cubic centimetre of the iron through the corresponding magnetic cycle; expressed in ergs this work is $\frac{1}{4\pi} \int HdB$.¹ To quote an example given by Fleming, it requires about 18 foot-pounds of work to make a complete magnetic cycle in a cubic foot of wrought iron, strongly magnetized first one way and then the other, the work so expended taking the form of heat in the mass.

Fig. 9 shows diagrammatically a convenient arrangement described by Ewing (see *Proc. Inst. C.E.* vol. cxxvi., and *Phil. Trans.*, 1893A, p. 987) for carrying out ballistic tests by which either the simple *B-H* curve (Fig. 6) or the hysteresis curve (Figs. 7 and 8) can be determined. The sample under test is prepared in the form of a ring *A*, upon which are wound the induction and the magnetizing coils; the latter should be wound evenly over the whole ring, though for the sake of clearness only part of the winding is indicated in the diagram. The magnetizing current, which is derived from the storage battery *B*, is regulated by the adjustable resistance *R* and measured by the galvanometer *G*. The current passes through the rocking key *K*, which, when thrown over to the right, places *a* in contact with *c* and *b* with *d*, and when thrown over to the left, places *a* in contact with *e* and *b* with *f*. When the switch *S* is closed, *K* acts simply as a commutator or current-reverser, but if *K* is thrown over from right to left while *S*

is opened, not only is the current reversed, but its strength is at the same time diminished by the interposition of the adjustable resistance *R*. The induction coil wound upon the ring is connected to the ballistic galvanometer *G*, in series with a large permanent resistance *R*. In the same circuit is also included the induction coil *E*, which is used for standardizing the galvanometer; this secondary coil is represented in the diagram by three turns of wire wound over a much longer primary coil. The short-circuit key *F* is kept closed except when an observation is about to be made; its object is to arrest the swing of the d'Arsonval galvanometer *G*. By means of the three-way switch *C* the battery current may be sent either into the primary of *E*, for the purpose of calibrating the galvanometer, or into the magnetizing coil of the ring under test. When it is desired to obtain a simple curve of induction such as that in Fig. 6, *S* is kept permanently closed, and corresponding values of *H* and *B* are determined by one of the two methods already described, the strength of the battery-current being varied by means of the adjustable resistance *R*. When a hysteresis curve is to be obtained, the procedure is as follows:—the current is first adjusted by means of *R* to such a strength as will fit it to produce the greatest + and - values of the magnetizing force which it is intended to apply in the course of the cycle; then it is reversed several times, and when the range of the galvanometer throws has become constant, half the extent of an excursion indicates the induction corresponding to the extreme value of *H*, and gives the point *a* in the curve Fig. 7. The reversing key *K* having been put over to the left side, the short-circuit key *S* is suddenly opened;

this inserts the resistance *R*, which has been suitably adjusted beforehand, and thus reduces the current and therefore the magnetizing force to a known value. The galvanometer throw which results from the change of current measures the amount by which the induction is reduced, and thus a second point on the curve is found. In a similar manner, by giving different values to the resistance *R*, any desired number of points between *a* and *c* in the curve can be determined. To continue the process, the key *K* is turned over to the right-hand side, and then, while *S* is open, is turned back, thereby not only reversing the direction of the

Fig. 9.

current, but diminishing its strength by an amount depending upon the previous adjustment of *R*. In this way points can be found lying anywhere between *c* and *d* of Fig. 7, and the determination of the downward limb of the curve is therefore completed. As the return curve, shown in Fig. 8, is merely an inverted copy of the other, no separate determination of it is necessary.

In Fig. 10 (Fleming, *Magnets and Electric Currents*, p. 193) are shown three very different types of hysteresis curves, characteristic of the special qualities of the metals from which they were respectively obtained. The distinguishing feature of the first is the steepness of its outlines; this indicates that the induction increases rapidly in relation to the magnetic force, and hence the metal is well suited for the construction of dynamo magnets. The second has a very small area, showing that the work done

¹ Warburg, *Wied. Ann.* vol. xiii. (1881), p. 141; Ewing, *Phil. Trans.*, 1885, vol. ii. p. 549; Hopkinson, *Phil. Trans.*, 1885, vol. ii. p. 466. For a simple proof, see Ewing, *Magnetic Induction* (London, 1900), p. 99. Hopkinson pointed out that the greatest dissipation of energy which can be caused by a to-and-fro reversal is approximately represented by

Coercive force \times *maximum induction* $\div \pi$.

in reversing the magnetization is small; the metal is therefore adapted for use in alternating current transformers. On the other hand, the form of the third curve, with its large intercepts on the axes of H and B, denotes that the specimen to which it relates possesses both

Fig. 10

retentiveness and coercive force in a high degree; such a metal would be chosen for making good permanent magnets.

Steinmetz (*Electrician*, vol. xxvi. p. 261; vol. xxviii. pp. 384, 408, 425) has called attention to a simple relation which appears to exist between the amount of energy dissipated in carrying a piece of iron or steel through a magnetic cycle, and the limiting value of the induction reached in the cycle. Denoting by W the work in ergs done upon a cubic centimetre of the metal ($= \frac{1}{4\pi} \int HdB$ or $\int HdI$), he finds $W = \eta B^{1.6}$ approximately, where η is a number, called the *hysteretic constant*, depending upon the metal, and B is the maximum induction. The value of the constant η ranges in different metals from about 0.001 to 0.04; in soft iron and steel it is said to be generally not far from 0.002. Steinmetz's formula may be tested by taking a series of hysteresis curves between different limits of B, measuring their areas by a planimeter, and plotting the logarithms of these divided by 4π as ordinates against logarithms of the corresponding maximum values of B as abscissae. The curve thus constructed should be a straight line inclined to the horizontal axis at an angle θ , the tangent of which is 1.6. Ewing and Klaassen (*Phil. Trans.*, 1893A, p. 1017) have in this manner examined how nearly and within what range a formula of the type $W = \eta B^e$ may be taken to represent the facts. The results of an example which they quote in detail may be briefly summarized as follows:—

Limits of B.	Hysteretic Constant η	Index e ($= \tan \theta$)	Degrees θ
200 to 500	...	1.9	62.25
500 to 1000	...	1.68	59.25
1000 to 2000	...	1.55	57.25
2000 to 8000	0.01	1.475	55.75
8000 to 14000	0.00134	1.70	59.50

It is remarked by the experimenters that the value of the index e is by no means constant, but changes in correspondence with the successive well-marked stages in the process of magnetization. But though a formula of this type has no physical significance, and cannot be accepted as an equation to the actual curve of W and B, it is nevertheless the case that by making the index $e = 1.6$, and assigning a suitable value to η , a formula may be obtained giving an approximation to the truth which is sufficiently close for the ordinary purposes of electrical engineers, especially when the limiting value of B is neither very great nor very small. Mr Alexander Siemens (*Journ. Inst. Elec. Eng.*, 1894, p. 229) states that in the hundreds of comparisons of test pieces which have been made at the works of his firm, Steinmetz's law has been found to be practically correct.¹ An interesting collection of W-B curves embodying the results of actual experiments by Ewing and Klaassen on different specimens of metal is given in Fig. 11. It has been shown by Kennelly (*Electrician*, vol. xxviii. p. 666) that Steinmetz's

formula gives approximately correct results in the case of nickel. Working with two different specimens, he found that the hysteresis loss in ergs per cubic centimetre (W) was fairly represented by $0.00125B^{1.6}$ and $0.00101B^{1.6}$ respectively, the maximum induction ranging from about 300 to 3000. The applicability of the law to cobalt has been investigated by Fleming (*Phil. Mag.*, Sept. 1899, p. 271), who used a ring of cast cobalt containing about 96 per cent. of the pure metal. The logarithmic curves which accompany

Fig. 11.—a, Fine steel wire 0.257 mm. diam.; b, fine iron wire 0.34 mm. diam.; c, fine iron wire 0.2475 mm. diam.; d, thin sheet iron 0.47 mm. thick; e, iron wire 0.602 mm. diam.; f, iron wire 0.975 mm. diam.; g, sheet iron 1.95 mm. thick; h, thin sheet iron 0.367 mm. thick; i, very soft iron wire.

his paper demonstrate that within wide ranges of maximum induction $W = 0.01B^{1.6} = 0.527I^{1.62}$ very nearly. Fleming rightly regards it as not a little curious that, for materials differing so much as this cast cobalt and soft annealed iron, the hysteretic exponent should in both cases be so near to 1.6. After pointing out that, since the magnetization of the metal is the quantity really concerned, W is more appropriately expressed in terms of I, the magnetic moment per unit of volume, than of B, he suggests an experiment to determine whether the mechanical work required to effect the complete magnetic reversal of a crowd of small compass needles (representative of magnetic molecules) is proportional to the 1.6th power of the aggregate maximum magnetic moment before or after completion of the cycle.

The diagram, Fig. 12, contains examples of ascending induction curves characteristic of wrought iron, cast iron,

Fig. 12.

cobalt, and nickel. These are to be regarded merely as typical specimens, for the details of a curve depend largely upon the physical condition and purity of the material; but they show at a glance how far the several metals

¹ Some experiments by Baily showed that hysteresis ceased to increase when B was carried beyond 23,000. This value of B corresponds to $I = 1640$, the saturation point for soft iron.—*Brit. Assoc. Rep.*, 1895, p. 635.

differ from and resemble one another as regards their magnetic properties. Curves of magnetization (which express the relation of I to H) have a close resemblance to those of induction; and indeed, since $B = H + 4\pi I$, and $4\pi I$ (except in extreme fields) greatly exceeds H in numerical value, we may generally, without serious error, put $I = B/4\pi$, and transform curves of induction into curves of magnetization by merely altering the scale to which the ordinates are referred. A scale for the approximate transformation for the curves in Fig. 12 is given at the right-hand side of the diagram, the greatest error introduced by neglecting $H/4\pi$ not exceeding 0.6 per cent. A study of such curves as these reveals the fact that there are three distinct stages in the process of magnetization. During the first stage, when the magnetizing force is small, the magnetization (or the induction) increases rather slowly with increasing force; this is well shown by the nickel curve in the diagram, but the effect would be no less conspicuous in the iron curve if the abscissæ were plotted to a larger scale. During the second stage small increments of magnetizing force are attended by relatively large increments of magnetization, as is indicated by the steep ascent of the curve. Then the curve bends over, forming what is often called a "knee," and a third stage is entered upon, during which a considerable increase of magnetizing force has little further effect upon the magnetization. When in this condition the metal is popularly said to be "saturated." Under increasing magnetizing forces, greatly exceeding those comprised within the limits of the diagram, the magnetization does practically reach a limit, the maximum value being attained with a magnetizing force of less than 2000 for wrought iron and nickel, and less than 4000 for cast iron and cobalt. The induction, however, continues to increase indefinitely, though very slowly. These observations have an important bearing upon the molecular theory of magnetism, which will be referred to later.

Curves of Permeability and of Susceptibility.—The relations of $\mu (= B/H)$ to B , and of $\kappa (= I/H)$ to I , may be instructively exhibited by means of curves like those constructed by Rowland (see *Ency. Brit.*, MAGNETISM, vol. xv. p. 256). Recent experiments show that if the magnetizing force is carried far enough, the permeability

Fig. 13.

curve always becomes convex to the horizontal axis, instead of meeting it in the manner indicated in Rowland's diagrams. In Fig. 13 a curve given by an experiment in which the highest magnetizing force was 585 is compared with Rowland's curve for iron (Bidwell, *Proc. Roy. Soc.* vol. xl. (1886), p. 495). Rowland's experiment was carried only as far as the point marked X, corresponding to a magnetizing force of 65 and an induction of nearly 17,000. In

the other experiment, though the magnetizing force was further increased no less than ninefold, the induction reached only 19,800. It is seen that soon after the limit of Rowland's observations is passed, the curve, instead of continuing in an almost straight line to meet the horizontal axis, bends off asymptotically, the ultimate value of the permeability still being as much as 33.9.

Ballistic Method with Yoke.—Hopkinson (*Phil. Trans.*, 1885, part ii. p. 455) introduced a modification of the usual ballistic arrangement which presents the following advantages:—(1) very considerable magnetizing forces can be applied with ordinary means; (2) the samples to be tested, having the form of cylindrical bars, are more easily prepared than rings or wires; (3) the actual induction at any time can be measured, and not only changes of induction. On the other hand, a very high degree of accuracy is not claimed for the results. Fig. 14 shows the apparatus by which the ends of the bar are prevented from exerting any material demagnetizing force, while the permeance of the magnetic circuit is at the same time increased. AA, called the "yoke," is a block of annealed wrought iron about 18 inches long, $6\frac{1}{2}$ inches wide, and 2 inches thick, through which is cut a rectangular opening to receive the two magnetizing coils BB. The test bar CC, which slides through holes bored in the yoke, is divided near the middle into two parts, the ends which come into contact being faced true and square. Between the magnetizing coils is

Fig. 14

a small induction coil D, which is connected with a ballistic galvanometer. The induction coil is carried upon the end of one portion of the test bar, and when this portion is suddenly drawn back, the coil slips off and is pulled out of the field by an india-rubber spring. This causes a ballistic throw proportional to the induction through the bar at the moment when the two portions were separated. With such an arrangement it is possible to submit the sample to any series of magnetic forces, and to measure its magnetic state at the end. The uncertainty with which the results are affected depends chiefly upon the imperfect contact between the bar and the yoke and also between the ends of the divided bar. It is probable that Hopkinson did not attach sufficient importance to the demagnetizing action of the cut (cf. Ewing, *Phil. Mag.*, Sept. 1888, p. 274), and that the values which he assigned to H are consequently somewhat too high. He applied his method with good effect, however, in testing a large number of commercial specimens of iron and steel, the magnetic constants of which are given in a table accompanying his paper. When it is not required to determine the residual magnetization, there is no necessity to divide the sample bar, and ballistic tests may be made in the ordinary way—by steps or by reversals—the source of error due to the transverse cut thus being avoided. Ewing has devised an arrangement in which two similar test bars are placed side by side; each bar is surrounded by a magnetizing coil, the two coils being connected to give opposite directions of magnetization, and each pair of ends is connected by a short massive block of soft iron having holes bored through it to fit the bars, which are clamped in position by

set-screws. Induction coils are wound on the middle parts of both bars, and are connected in series. With this arrangement it is possible to find the actual value of the magnetizing force, corrected for the effects of joints and other sources of error. Two sets of observations are taken, one when the blocks are fixed at the ends of the bars, and another when they are nearer together, the clear length of the bars between them and of the magnetizing coils being reduced to one-half. If H_1 and H_2 be the values of $4\pi in/l$ and $4\pi i \frac{n}{2} \frac{l}{2}$ for the same induction B, it can be shown that the true magnetizing force is $H = H_1 - (H_2 - H_1)$. The method, though tedious in operation, is very accurate, and is largely employed for determining the magnetic quality of bars intended to serve as standards.

Traction Methods.—The induction or the magnetization may be measured by observing the force required to draw apart the two portions of a divided rod or ring when held together by their mutual attraction. If a transverse cut is made through a bar whose magnetization is I and the two ends are placed in contact, it can be shown that this force is $2\pi I^2$ dynes per unit of area (see MAGNETISM, *Ency. Brit.* vol. xv. p. 243); and if the magnetization of the bar is due to an external field H produced by a magnetizing coil or otherwise, there is an additional force equal to HI. Thus the whole force, when the two portions of the bar are surrounded by a loosely-fitting magnetizing coil, is

$$F = 2\pi I^2 + HI$$

expressed as dynes per square centimetre. If each portion of the bar has an independent magnetizing coil wound tightly upon it, we have further to take into account the force due to the mutual action of the two magnetizing coils, which assists the forces already considered. This is equal to $H^2/8\pi$ per unit of sectional area. In the case supposed therefore the total force per square centimetre is

$$\begin{aligned} F &= 2\pi I^2 + HI + \frac{H^2}{8\pi} \\ &= \frac{(4\pi I + H)^2}{8\pi} \\ &= \frac{B^2}{8\pi} \end{aligned}$$

The equation $F = B^2/8\pi$ is often said to express "Maxwell's law of magnetic traction" (Maxwell, *Electricity and Magnetism*, §§ 642-646). It is of course true for permanent magnets, where $H = 0$, since then $F = 2\pi I^2$; but if the magnetization is due to electric currents, the formula is only applicable in the special case when the mutual action of the two magnets upon one another is supplemented by the electrodynamic attraction between separate magnetizing coils rigidly attached to them.¹

The traction method was first employed by Bidwell (*Proc. Roy. Soc.* vol. xl. p. 486), who in 1886 published an account of some experiments in which the relation of magnetization to magnetic field was deduced from observations of the force in grammes weight which just sufficed to tear asunder the two halves of a divided ring electromagnet when known currents were passing through the coils. He made use of the expression

$$F = Wg = 2\pi I^2 + HI,$$

where W is the weight in grammes per square centimetre of sectional area, and g is the acceleration due to gravity, which was taken as 981. The term for the attraction between the coils was omitted as negligibly small (see *Phil. Mag.* vol. xxix. p. 440). The values assigned to H were calculated from $H = 2ni/r$, and ranged from 3.9 to 585,

¹ Since in most practicable experiments H^2 is negligible in comparison with B^2 , the force may be taken as $B^2/8\pi$ without sensible error.

but inasmuch as no account was taken of any demagnetizing action which might be due to the two transverse cuts, it is probable that they are somewhat too high. The results nevertheless agree very well with those for annealed wrought iron obtained by other methods. Below is given a selection from Bidwell's tables showing corresponding values of magnetizing force, weight supported, magnetization, induction, susceptibility, and permeability:—

H	W	I	B	κ	μ
3.9	2,210	587	7,390	151.0	1889.1
5.7	3,460	735	9,240	128.9	1621.3
10.3	5,400	918	11,550	89.1	1121.4
22.2	8,440	1147	14,450	51.7	650.9
40	9,680	1226	15,460	30.7	386.4
115	12,170	1370	17,330	11.9	150.7
208	13,810	1452	18,470	7.0	88.8
362	14,740	1489	19,080	4.1	52.7
465	15,275	1508	19,420	3.2	41.8
585	15,905	1530	19,820	2.6	33.9

A few months later Bosanquet (*Phil. Mag.* vol. xxii. p. 535) experimented on the relation of tractive force to magnetic induction. Instead of a divided ring he employed a divided straight bar, each half of which was provided with a magnetizing coil. The joint was surrounded by an induction coil connected with a ballistic galvanometer, an arrangement which enabled him to make an independent measurement of the induction at the moment when the two portions of the bar were separated. He showed that there was, on the whole, a fair agreement between the values determined ballistically and those given by the formula $B = \sqrt{8\pi F}$. The greatest weight supported in the experiments was 14,600 grammes per square cm., and the corresponding induction 18,500 units. Taylor Jones more recently found a good agreement between the theoretical and the observed values of the tractive force in fields ranging up to very high intensities (*Phil. Mag.* vol. xxxix. (1895), p. 254, and vol. xli. (1896), p. 153).

Permeameters.—Several instruments in which the traction method is applied have been devised for the rapid measurement of induction or of magnetization in commercial samples of iron and steel. The earliest of these is S. P. Thompson's permeameter (*Journ. Sci. Arts.* vol. xxxviii. (1890), p. 885), which consists of a rectangular block of iron shaped like Hopkinson's yoke, and slotted out in the same way to receive a magnetizing coil (Fig. 15); the block is bored through at the upper end only, and its inner face opposite the hole is made quite flat and smooth. The sample has the form of a thin rod, one end of which is faced true; it is slipped into the magnetizing coil from above, and when the current is turned on, its smooth end adheres tightly to the surface of the yoke. The force required to detach it is measured by a registering spring balance, which is clamped to the upper end of the rod, and thence the induction or the magnetization is deduced by applying the formula

$$\frac{(B - H)^2}{8\pi} = 2\pi I^2 = \frac{Pg}{S},$$

where P is the pull in grammes weight, S the sectional area of the rod in square cm., and $g = 981$. If the pull is measured in pounds and the area in square inches, the formula may be written $B = 1317 \times \sqrt{P/S} + H$. The instrument exhibited by Thompson would, without undue heating, take a current of 30 amperes, which was sufficient to produce a magnetizing force of 1000 units. A testing

Fig. 15.

apparatus of a similar type devised by Kapp (*Journ. Inst. Elec. Eng.* vol. xxiii. p. 199) differs only in a few details from Thompson's permeameter. Ewing has described an arrangement in which the test bar has a soft-iron pole piece clamped to each of its ends; the pole pieces are joined by a long well-fitting block of iron, which is placed upon them (like the "keeper" of a magnet), and the induction is measured by the force required to detach the block. In all such measurements a correction should be made in respect of the demagnetizing force due to the joint, and unless the fit is very accurate the demagnetizing action will be variable. In the magnetic balance of du Bois (*Magnetic Circuit*, p. 346) the uncertainty arising from the presence of a joint is avoided, the force measured being that exerted between two pieces of iron separated from each other by a narrow air-gap of known width. The instrument is represented diagrammatically in Fig. 16. The test-piece A, surrounded by a magnetizing coil, is clamped between two soft-iron blocks B, B'. YY' is a soft-iron yoke, which rocks upon knife-edges K, and constitutes the beam of the balance. The yoke has two projecting pieces C, C' at unequal distances from the knife-edges, and separated from the blocks B, B' by narrow air-gaps. The play of the beam is limited by a stop S and a screw R, the latter being so adjusted that when the end Y of the beam is held down the two air-gaps are of equal width. W is a

Fig. 16.

weight capable of sliding from end to end of the yoke along a graduated scale. When there is no magnetization, the yoke is in equilibrium; but as soon as the current is turned on, the block C is drawn downwards as far as the screw R will allow, for though the attractive forces F between B and C and between B' and C' are equal, the former has a greater moment. The weight W is moved along the scale until the yoke just tilts over upon the stop S; the distance of W from its zero position is then, as can easily be shown, proportional to F , and therefore to B^2 , and approximately to I^2 . The scale is graduated in such a manner that by multiplying the reading by a simple factor (generally 10 or 2) the absolute value of the magnetization is obtained. The actual magnetizing force H is of course less than that due to the coil; the corrections required are effected automatically by the use of a set of demagnetization lines drawn on a sheet of celluloid which is supplied with the instrument. The celluloid sheet is laid upon the squared paper, and in plotting a curve horizontal distances are reckoned from the proper demagnetization line instead of from the vertical axis. An improved but somewhat more complex form of the instrument is described in *Ann. d. Phys.* vol. ii. (1900), p. 317.

In Ewing's magnetic balance (*Journ. Inst. Elec. Eng.* vol. xxvii. p. 526) the value of the magnetic induction corresponding to a single stated magnetizing force is directly read off on a divided scale. The specimen, which has the form of a turned rod, 4 inches long and $\frac{1}{4}$ inch in diameter, is laid across the poles of a horseshoe electromagnet, excited by a current of such strength as to produce in the rod a magnetizing force $H=20$. One pole has a V-shaped notch for the rod to rest in; the surface of the other is slightly rounded, forming a portion of a cylinder, the axis of which is perpendicular to the direction of the length of the rod. The rod touches this pole at a single point, and is pulled away from it by the action of a lever, the long arm of which is graduated and carries a sliding weight. The position of the weight at the moment when contact is broken indicates the induction in the rod. The standard force $H=20$ was selected as being sufficiently low to distinguish between good and bad specimens, and at the same time sufficiently high to make the order of merit the same as it would be under stronger forces.

Measurement of Field Strength. Exploring Coil.—The old method of measuring field intensity by means of an induction coil with a standardized ballistic galvanometer (see *Ency. Brit.* vol. xv. p. 240) is still the one most generally employed. Convenient arrangements have been devised whereby the coil is suddenly reversed or withdrawn from the field by the action of a spring.

Bismuth Resistance.—The fact, which will be referred to later, that the electrical resistance of bismuth is very

greatly affected by a magnetic field has been applied in the construction of apparatus for measuring field intensity. A little instrument, supplied by Hartmann and Braun, contains a short length of fine bismuth wire wound into a flat double spiral, half an inch or thereabouts in diameter, and attached to a long ebonite handle. Unfortunately the effects of magnetization upon the specific resistance of bismuth vary enormously with changes of temperature; it is therefore necessary to take two readings of the resistance, one when the spiral is in the magnetic field, the other when it is outside.

Electric Circuit.—If a coil of insulated wire is suspended so that it is in stable equilibrium when its plane is parallel to the direction of a magnetic field, the transmission of a known electric current through the coil will cause it to be deflected through an angle which is a function of the field intensity.

Among recent applications of this principle one of the neatest is that described by Edser and Stansfield (*Phil. Mag.* vol. xxiv. p. 186), and used by them to test the stray fields of dynamos. An oblong coil about an inch in length is suspended from each end by thin strips of rolled German silver wire, one of which is connected with a spiral spring for regulating the tension, the other being attached to a torsion-head. Inside the torsion-head is a commutator for automatically reversing the current, so that readings may be taken on each side of zero, and the arrangement is such that when the torsion-head is exactly at zero the current is interrupted. To take a reading the torsion-head is turned until an aluminium pointer attached to the coil is brought to the zero position on a small scale; the strength of the field is then proportional to the angular torsion. The small current required is supplied to the coil from a single dry cell. The advantages of portability, very considerable range (from $H=1$ upwards), and fair accuracy are claimed for the instrument.

Polarized Light.—The intensity of a field may be measured by the rotation of the plane of polarization of light passing in the direction of the magnetic force through a transparent substance. If the field is uniform, $H = \theta/\omega d$, where θ is the rotation, d the thickness of the substance arranged as a plate at right angles to the direction of the field, and ω Verdet's constant for the substance.

For the practical measurement of field intensity du Bois has used plates of the densest Jena flint glass. These are preferably made slightly wedge-shaped, to avoid the inconvenience resulting from multiple internal reflections, and they must necessarily be rather thin, so that double refraction due to internal strain may not exert a disturbing influence. Since Verdet's constant is somewhat uncertain for different batches of glass even of the same quality, each plate should be standardized in a field of known intensity. As the source of monochromatic light a bright sodium burner is used, and the rotation, which is exactly proportional to H , is measured by an accurate polarimeter. Such a plate about 1 mm. in thickness is said to be adapted for measuring fields of the order of 1000 units. A part of one surface of the plate may be silvered, so that the polarized ray, after having once traversed the glass, is reflected back again; the rotation is thus doubled, and moreover, the arrangement is, for certain experiments, more convenient than the other.

MAGNETIZATION IN STRONG FIELDS.

Fields due to Coils.—The most generally convenient arrangement for producing such magnetic fields as are required for experimental purposes is undoubtedly a coil of wire through which an electric current can be caused to flow. The field due to a coil can be made as nearly uniform as we please throughout a considerable space; its intensity, when the constants of the coil are known, can be calculated with ease and certainty and may be varied at will through wide ranges, while the apparatus required is of the simplest character and can be readily constructed to suit special purposes. But when exceptionally strong fields are desired, the use of a coil is limited by the heating effect of the magnetizing current, the quantity of heat generated per unit of time in a coil of given dimensions increasing as the square of the magnetic field produced in its interior. In experiments on magnetic strains carried out by Nagaoka and Honda (*Phil. Mag.* vol. xlix. (1900),

p. 329) the intensity of the highest field reached in the interior of a coil was 2200 units. The coil used was 30 cm. in length, and was wound with twelve layers of wire having a total resistance of 0.63 ohm, the field produced by 1 ampere having the intensity of 38 units. The current employed must therefore have been nearly 60 amperes, and the quantity of heat generated per second upwards of 500 calories. This is probably the strongest field produced by a coil which has hitherto been employed in experimental work. There are indeed few purposes for which the field thus obtained would be available, because, if the circuit were closed for more than a brief period, the heat generated would quickly destroy the insulation of the wire. In 1890 some experiments in which a coil was used were made by du Bois (*Phil. Mag.* vol. xxix. pp. 253, 293) on the magnetization of iron, nickel, and cobalt under forces ranging from about 100 to 1250 units. Since the demagnetizing factor was 0.052, the strongest field due to the coil was about 1340; but though arrangements were provided for cooling the apparatus by means of ice, great difficulty was experienced owing to heating. Du Bois's results, which, as given in his papers, show the relation of H to the magnetic moment per unit of mass, have been reduced by Ewing to the usual form, and are indicated in Fig. 17, the earlier portions of the curves being sketched in from other data.

Fig. 17.

Fields due to Electromagnets.—The problem of determining the magnetization of iron and other metals in the strong fields formed between the poles of an electromagnet was first attacked by Ewing and Low. An account of their preliminary experiments by what they call the *isthmus method* was published in 1887 (*Proc. Roy. Soc.* vol. xlii. p. 200), and in the following year they described a more complete and perfect series (*Phil. Trans.* vol. clxxx. p. 221).

The sample to be inserted between the magnet poles was prepared in the form of a bobbin resembling an ordinary cotton reel, with a short narrow neck (constituting the "isthmus") and conical ends. Upon the central neck was wound a coil consisting of one or two layers of very fine wire, which was connected with a ballistic galvanometer for measuring the induction in the iron; outside this coil, and separated from it by a small and accurately determined distance, a second coil was wound, serving to measure the induction in the iron, together with that in a small space surrounding it. The difference of the ballistic throws taken with the two coils measured the intensity of the field in the space around the iron, and it also enabled a correction to be made for the non-ferrous space between the iron neck and the centre of the thickness of the inner coil. The pole-pieces of the electromagnet (see Fig. 18) were furnished with a pair of truncated cones *b b*, of soft iron forming an extension of the conical ends of the bobbin *c*. The most suitable form for the pole faces is investigated in the paper, and the conclusion arrived at is that to produce the greatest concentration of force upon the central neck, the cones should have a common vertex in the middle of the neck with a semi-vertical angle of $54^{\circ} 44'$, while the condition

for a uniform field is satisfied when the cones have a semi-vertical angle of $39^{\circ} 14'$; in the latter case the magnetic force in the air just outside is sensibly equal to that within the neck. A pair of cones having a semi-vertical angle of 45° were considered to combine high concentrative power with a sufficient approximation to uniformity of field.

In most of the experiments the measurements were made by suddenly withdrawing the bobbin from its place between the pole-pieces. Two groups of observations were recorded, one giving the induction in the inner coil and the other that in the outer coil. The value of the residual induction which persisted when the bobbin was drawn out was added to that of the induction measured, and thus the total induction in the iron was determined. The highest induction reached in these experiments was 45,350 units, more than twice the value of any previously recorded. The corresponding intensity of the outside field was 24,500, but, owing to the wide angle of the cones used (about $2 \times 63^{\circ}$), this was probably greater than the value of the magnetic force within the metal. The following table shows some results of other experiments in which H was believed to have sensibly the same value inside as outside the metal. Values of I are derived from $(B - H)/4\pi$ and of μ from B/H .

Fig. 18.

Metal.	H	B	I	μ
Swedish Iron	1,490	22,650	1680	15.20
	6,070	27,130	1680	4.47
	8,600	30,270	1720	3.52
	19,450	40,820	1700	2.10
	19,880	41,140	1700	2.07
Cast Iron	4,560	20,070	1230	4.40
	13,460	28,710	1210	2.13
	16,200	30,920	1170	1.91
	16,900	31,760	1180	1.88
Tool Steel	6,210	25,480	1530	4.10
	9,970	29,650	1570	2.97
	12,170	31,620	1550	2.60
	14,660	34,550	1580	2.36
	15,530	35,820	1610	2.31
Hard Nickel	2,220	7,100	390	3.20
	4,440	9,210	380	2.09
	7,940	12,970	400	1.63
	14,660	19,640	400	1.34
	16,000	21,070	400	1.32
Cobalt	1,350	16,000	1260	12.73
	4,040	18,870	1280	4.98
	8,930	23,890	1290	2.82
	14,990	30,210	1310	2.10

These results are of extreme interest, for they show that under sufficiently strong magnetizing forces the intensity of magnetization I reaches a maximum value, as required by Weber's theory of molecular magnetism. There appears to be no definite limit to the value to which the induction B may be raised, but the magnetization I attains a true saturation value under magnetizing forces which are in most cases comparatively moderate. Thus the magnetization which the sample of Swedish iron received in a field of 1490 was not increased (beyond the limits of experimental error) when the intensity of the field was multiplied more than 13-fold, though the induction was nearly doubled. When the saturation value of I has been reached, the relation of magnetic induction to magnetic force may be expressed by

$$B = H + \text{constant.}$$

The annexed table gives the saturation values of I for the particular metals examined by Ewing and Low :—

	Saturation Value of I.
Wrought iron	1700
Cast iron	1240
Nickel (0.75 per cent. iron)	515
" (0.56 " " ")	400
Cobalt (1.66 " " ")	1300

It is shown in the paper that the greatest possible force which the isthmus method can apply at a point in the axis of the bobbin is

$$F = 11.137 I_s \log_{10} \frac{b}{a}$$

I_s being the saturation value of the magnet poles, a the radius of the neck on which the cones converge, and b the radius of the bases of the cones.

Some experiments made by du Bois (*Phil. Mag.* vol. xxix. p. 293) with an electromagnet specially designed for the production of strong fields, confirm Ewing's results for iron, nickel, and cobalt. The method employed did not admit of the production of such high magnetizing forces, but was of special interest in that both B and I were measured optically—B by means of the rotation of a polarized ray inside a glass plate, as before described, and I by the rotation of a polarized ray reflected from the polished surface of the magnetized metal (see "Kerr's constant," MAGNETO-OPTICS). $H (= B - 4\pi I)$ was calculated from corresponding values of I and B.

In 1896 Taylor Jones (*Wied. Ann.* vol. lvii. p. 258, and *Phil. Mag.* vol. xxix. p. 293), working with du Bois's electromagnet and using a modification of the isthmus method, succeeded in pushing the induction B up to 74,200 with $H = 51,600$, the corresponding value of I being 1798, and of μ only 1.44. The diameter of the isthmus was 0.241 mm., and the electromagnet was excited by a current of 40 amperes.

Tractive Force of a Magnet.—Closely connected with the results just discussed is the question what is the greatest tractive force that can be exerted by a magnet. In the year 1852 Joule (*Phil. Mag.* [4], vol. iii. p. 32) expressed the opinion that no "force of current could give an attraction equal to 200 lb per square inch," or 14,000 grms. per square centimetre, and a similar view prevailed among high authorities more than twenty years later. For the greatest possible "lifting power" of permanent magnets this estimate is probably not very far from the truth, but it is now clearly understood that the force which can be exerted by an electromagnet, or by a pair of electromagnets with opposite poles in contact, is only limited by the greatest value to which it is practically possible to raise the magnetizing force H. This is at once evident when the tractive force due to magnetization is expressed as $2\pi I^2 + HI$. For fields of moderate intensity the first term of the expression is the most important, but when the value of H exceeds 12,000 or thereabouts, the second preponderates, and with the highest values that have been actually obtained, HI is several times greater than $2\pi I^2$. If H could be increased without limit, so also could the tractive force. The following table shows the greatest "lifting powers" experimentally reached at the dates mentioned :—

Observer.	Kilos per sq. cm.	Lb. per sq. in.	Date
Joule	12.3	175	1852

MAGNETIZATION IN VERY WEAK FIELDS.

Some interesting observations have been made of the effects produced by very small magnetic forces. It was

first pointed out by Baur (*Wied. Ann.* vol. xi. (1880), p. 399) that in weak fields the relation of the magnetization I to the magnetizing force H is approximately expressed by an equation of the form

$$I = aH + bH^2,$$

or

$$\kappa = \frac{I}{H} = a + bH,$$

whence it appears that within the limits of Baur's experiments the magnetization curve is a parabola, and the susceptibility curve an inclined straight line, κ being therefore a known function of H. If these equations could be assumed to hold when H is indefinitely small, it would follow that κ has a finite initial value, from which there would be no appreciable deviation in fields so weak that bH was negligibly small in comparison with a . Such an assumption could not, however, without dangerous extrapolation, be founded upon the results of Baur's experiments, which did not go far enough to justify it. In some experiments carried out in 1887, Rayleigh (*Phil. Mag.* vol. xxiii. p. 225) approached very much more nearly than Baur to the zero of magnetic force. Using an un-annealed Swedish iron wire, he found that when H was gradually diminished from 0.04 to 0.00004 C.G.S. unit, the ratio of magnetization to magnetizing force remained sensibly constant at 6.4, which may therefore with great probability be assumed to represent the initial value of κ for the specimen in question. Experiments with annealed iron gave less satisfactory results, on account of the slowness with which the metal settled down into a new magnetic state, thus causing a "drift" of the magnetometer needle, which sometimes persisted for several seconds. Apart from this complication, it appeared that I was proportional to H when the value of H was less than 0.02.

The observations of Baur and Rayleigh have been confirmed and discussed by (among others) Schmidt (*Wied. Ann.* vol. liv. p. 655), who found the limiting values of κ to be 7.5 to 9.5 for iron, and 11.2 to 13.5 for steel, remaining constant up to $H = .06$; by Cullmann (*Elekt. Zeit.* vol. xiv. p. 345; *Wied. Ann.* vol. lvi. p. 602); and by Holborn (*Berl. Ber.* 1897, p. 95, and *Wied. Ann.* vol. lxi. p. 281). The latter gives values of the constants a and b for different samples of iron and steel, some of which are shown in the following table :—

Metal.	$\kappa = a + bH$	
	a	b
English tungsten steel	8.90	0.264
Tungsten steel, hardened	2.23	0.032
Silver steel	8.66	0.384
Tool steel	8.30	0.400
Refined steel	11.28	1.92
Cast iron	3.16	0.236
Soft iron	16.6	18.6
Hard drawn iron	5.88	1.76

For most samples of steel the straight-line law was found to hold approximately up to $H = 3$; in the case of iron and of soft steel the approximation was less close.

The behaviour of nickel in weak fields has been observed by Ewing (*Phil. Trans.* vol. clxxix.A (1888), p. 325), who found that the initial value of κ was 1.7, and that it remained sensibly constant until H had reached a value of about five units. While therefore the initial susceptibility of nickel is less than that of iron and steel, the range of magnetic force within which it is approximately constant is about one hundred times greater. Ewing has also made a careful study (*Proc. Roy. Soc.* vol. xlvi. (1889), p. 269) of "magnetic viscosity" under small forces—the cause of the magnetometer "drift" referred to by Rayleigh. On the application of a small magnetizing force to a bar of soft annealed iron, a certain intensity of magnetization is instantly produced; this, however, does not remain constant, but slowly increases for some seconds or even minutes, and may ultimately attain a value nearly twice as great as that observed immediately after the force was

applied.¹ When the magnetizing current is broken, the magnetization at once undergoes considerable diminution, then gradually falls to zero, and a similar sudden change followed by a slow one is observed when a feeble current is reversed. Ewing draws attention to a curious consequence of this time-lag. By the alternate application and withdrawal of a small magnetizing force a cyclic condition may be established in an iron rod. If now the alternations are performed so rapidly that time is not allowed for more than the first sudden change in the magnetization, there will be no hysteresis loss, the magnetization exactly following the magnetizing force. Further, if the alternations take place so slowly that the full maximum and minimum values of the magnetization are reached in the intervals between the reversals, there will again be no dissipation of energy. But at any intermediate frequency the ascending and descending curves of magnetization will enclose a space and energy will be dissipated. It is remarkable that the phenomena of magnetic viscosity are much more evident in a thick rod than in a thin wire, or even in a large bundle of thin wires. In hardened iron and steel the effect can scarcely be detected, and in weak fields these metals exhibit no magnetic hysteresis of any kind.

CHANGES OF DIMENSIONS ATTENDING MAGNETIZATION.

It is well known that the form of a piece of ferromagnetic metal is in general slightly changed by magnetization. The phenomenon was first noticed by Joule, whose experiments are described in papers published in 1842 and 1847. For nearly forty years nothing of importance was added to Joule's results, with the exception of Barrett's discovery that a nickel bar contracts when magnetized, and the short statement in *Ency. Brit.* vol. xv. p. 268, included nearly all that was known on the subject down to the year 1883. Much new light has, however, been recently thrown upon a class of phenomena which cannot fail to have an important bearing upon any complete molecular theory of magnetism.² According to Joule's observations, the length of a bar of iron or soft steel was increased by magnetization, the elongation being proportional up to a certain point to the square of the intensity of magnetization; but when the "saturation point" was approached the elongation was less than this law would require, and a stage was finally reached at which further increase of the magnetizing force produced little or no effect upon the length. From data contained in Joule's paper it may be calculated that the strongest external

¹ The same phenomenon is exhibited in a less marked degree when soft iron is magnetized in stronger fields (Ewing, *Phil. Trans.* vol. clxxvi. (1885), p. 569.

field H_0 produced by his coil was about 126 C.G.S. units, but since the dimensional ratio of his bars was comparatively small, the actual magnetizing force H must have been materially below that value. In 1885 it was shown by Bidwell, in the first of a series of papers on the subject, that if the magnetizing force is pushed beyond the point at which Joule discontinued his experiments, the extension of the bar does not remain unchanged, but becomes gradually less and less, until the bar, after first returning to its

Fig. 19.

original length, ultimately becomes actually shorter than when in the unmagnetized condition. The elongation is generally found to reach a maximum under a magnetizing force of 50 to 120 units, and to vanish under a force of 200 to 400, retraction occurring when still higher forces are applied. In order to meet the objection that the phenomenon might be due to electromagnetic action between the coil and the rod, Bidwell made some experiments with iron rings, and found that the length of their diameters varied under magnetization in precisely the same manner as the length of a straight rod. Fig. 19 shows the changes observed in the dimensions of two iron rings and an iron rod in fields up to 450 units. Experiments were afterwards made with rods of iron, nickel, and cobalt, the external field being carried up to the high value of 1500 units. The results are indicated in Fig. 20. It

Fig. 20.

appears that the contraction which followed the initial extension of the iron reached a limit in fields of 1000 or 1100. Nickel exhibited retraction from the very beginning (as observed by Barrett), its greatest change of length considerably exceeding that undergone by iron; in a field of 800 the original length was diminished by as much as $1/40,000$ part, but stronger forces failed to produce any further effect. The curve for cobalt is a very remarkable one. Little or no change of length was observed until the strength of the field H_0 reached about 50; then the rod began to contract, and after passing a minimum at

$H_0 = 400$, recovered its original length at $H_0 = 750$; beyond this point there was extension, the amount of which was still increasing fast when the experiment was stopped at $H_0 = 1400$. Similar results were obtained with three different samples of the metal. Roughly speaking, therefore, cobalt behaves oppositely to iron.

Joule and others experimented with hardened steel, but failed to find a key to the results they obtained, which are rather complex, and have been thought to be inconsistent. The truth appears to be that a hardened steel rod generally behaves like one of iron or soft steel in first undergoing extension under increasing magnetizing force, and recovering its original length when the force has reached a certain critical value, beyond which there is contraction. But this "critical value" of the force is found to depend in an unexpected manner upon the hardness of the steel; the critical value diminishes as the hardness becomes greater up to a certain point, corresponding to a yellow temper, after which it increases and with the hardest steel becomes very high. For steel which has been made red-hot, suddenly cooled, and then let down to a yellow temper, the critical value of the magnetizing force is smaller than for steel which is either softer or harder; it is indeed so small that the metal contracts like nickel even under weak magnetizing forces, without undergoing any preliminary extension that can be detected.

Joule also made experiments upon iron wires under tension, and appears to have formed the conclusion (which has been often quoted as if it were a demonstrated fact) that under a certain critical tension (differing for different specimens of iron but independent of the magnetizing force) magnetization would produce no effect whatever upon the dimensions of the wire.¹ What actually happens when an iron wire is loaded with various weights is clearly shown in Fig. 21. Increased tension merely has the

Fig. 21.

effect of diminishing the maximum elongation and hastening the contraction; with the two greatest loads used in the experiment there was indeed no preliminary extension at all.² The effects of tension upon the behaviour of a nickel wire are of a less simple character. In weak fields the magnetic contraction is always diminished by pulling stress; in strong fields the contraction increases under a small load and diminishes under a heavy one. Cobalt, curiously enough, was found to be quite unaffected by tensile stress.

Certain experiments by Knott on magnetic twist, which will be referred to later, led him to form the conclusion that in an iron wire carrying an electric current the

¹ In *Ency. Brit.* vol. xv. p. 269 it is stated that in the case of a certain wire loaded with a weight of 600 lb there was neither extension nor contraction, even with a very large current. This, however, was merely a conjecture of Joule's which an experiment would have disproved.

² The loads were successively applied in decreasing order of magnitude. They are indicated in Fig. 21 as kilos per sq. cm.

magnetic elongation would be increased. This forecast was shown by Bidwell to be well founded. The effect produced by a current is exactly opposite to that of tension, raising the elongation curve instead of depressing it. In the case of a wire 0.75 mm. in diameter the maximum elongation was nearly doubled when a current of two amperes was passing through the iron, while the "critical value" of the field was increased from 130 to 200. Yet notwithstanding this enormous effect in iron, the action of a current upon nickel and cobalt turned out to be almost inappreciable.

Some experiments were next undertaken with the view of ascertaining how far magnetic changes of length in iron were dependent upon the hardness of the metal, and the unexpected result was arrived at that softening produces the same effect as tensile stress; it depresses the elongation curve, diminishing the maximum extension, and reducing the "critical value" of the magnetizing force. A hard drawn wire showed a maximum elongation of 45 ten-millionths, the critical field being (by extrapolation) 560. After the wire had been annealed, its maximum elongation was only 7 and the critical field 140. A thoroughly well annealed ring of soft iron showed no extension at all, beginning to contract under the smallest magnetizing forces; in a field of 506, when the experiment had to be stopped owing to the heating of the coil, the retraction had reached 75 ten-millionths, and appeared to be still far from its limiting value. A ring made of the same iron, but unannealed, showed a maximum elongation of 33, the critical value of the field being 420. The experiments were not sufficiently numerous to indicate whether, as is possible, there is a critical degree of hardness for which the height of the elongation curve is a maximum.

Finally, experiments were made to ascertain the effect of magnetization upon the dimensions of iron rings in directions perpendicular to the magnetization, and upon the volume of the rings. Four brass rods were hard-soldered to a short cylindrical iron ring, two of them forming prolongations of a diameter, while the other two were attached to the edges, opposite to one another and parallel to the axis of the ring. The first pair served to communicate to the measuring instrument the effects of changes along the lines of magnetization, the other pair those perpendicular to the magnetization. It was found that the curve showing the relation of transverse changes of dimensions to magnetizing force was similar in general character to the familiar elongation curves, but the signs were reversed; the curve was inverted, indicating at first retraction, which, after passing a maximum and vanishing in a critical field, was succeeded by elongation. The curve showing the circumferential (or longitudinal) changes was also plotted, and from the two curves thus obtained it was easy, on the assumption that the metal was isotropic in directions at right angles to the magnetization, to calculate changes of volume; for if circumferential elongation be denoted by l_1 , and transverse elongation by l_2 , then the cubical dilatation (+ or -) = $l_1 + 2l_2$ approximately. If l_1 were exactly equal to $-2l_2$ for all values of the magnetizing force, it is clear that the volume of the ring would be unaffected by magnetization. In the case of the ring in question, the circumferential changes were in weak fields less than twice as great as the transverse ones, while in strong fields they were more; under increasing magnetic force therefore the volume of the ring was first diminished, then it regained its original value (for $H = 90$), and ultimately increased. It was also shown that annealing, which has such a large effect upon circumferential (or longitudinal) changes, has almost none upon transverse ones. Hence the changes of volume undergone by a given sample of wrought iron under

increasing magnetization must depend largely upon the state of the metal as regards hardness; there may be always contraction, or always expansion, or first one and then the other.

Many of the above-described experiments have been repeated, and the results confirmed by other workers. As regards the effect of magnetization upon volume there are some discrepancies. Nagaoka and Honda, employing a fluid dilatometer, found that the volume of several specimens of iron and steel was always slightly increased, no diminution in low fields being indicated. Rhoads, finding that the height of the elongation curve is greater for strips of sheet iron cut parallel to the direction of the fibrous structure than for strips cut at right angles to it, conjectures that in perfectly isotropic iron there would be no change of volume. In order to avoid complications arising from imperfect homogeneity and isotropy, by which metallic solids must always be in some degree affected, Hurmuzescu experimented with solutions of salts of iron, and found that their volume was diminished by the action of a magnetic field. Nickel, according to Cantone's observations, appeared to be slightly diminished in volume by magnetization; and a similar result was at first obtained by Nagaoka and Honda, but when they afterwards tested a specimen of greater purity a small increase of volume was observed. The question again arises how far these results are dependent upon the physical condition of the metal. Knott has carried out an exhaustive series of experiments on the strains produced in iron, steel, nickel, and cobalt tubes in the magnetic field. Tubes of various dimensions were subjected to fields of various intensities, and measurements were made of changes in (1) volume of the bore, (2) length of the tube, (3) volume of the material of the tube, (4) external changes of volume when the tube was plugged. The important results obtained are of too complex a nature to be fully described here; the following are the general conclusions drawn:—(i.) the strain is one in which there is comparatively little change of volume, but considerable change of form; (ii.) except in the case of very thin walls, a circular element in any transverse plane perpendicular to the axis of the cylinder becomes, when the cylinder is magnetized parallel to its axis, an ellipse with its major axis pointing towards the axis of the tube. When the walls are thin, the ellipse has its minor axis pointing towards the axis of the tube. The ellipse in both cases increases in eccentricity as the distance from the axis diminishes. It may be added that the measurements of class (3) showed that in iron there was always a slight increase of volume, and in nickel and cobalt a slight decrease. Honda subjected tubes of iron, steel, and nickel to the simultaneous action of longitudinal and circular fields, and observed the changes of length which occurred when one of the fields was varied, while the other remained constant at different successive values from zero upwards. The experimental results agreed in sign though not in magnitude with those calculated from the changes produced by simple longitudinal magnetization, discrepancies being partly accounted for by the fact that the metals employed were not actually isotropic. The complicated hysteresis effects which attend the magnetic elongation and contraction of iron, nickel, and cobalt have been studied by Nagaoka.

Attempts have been made to explain magnetic deformation by various theories of magnetic stress,¹ notably that

¹ For a discussion of theories of magnetic stress, with copious references, see Nagaoka, *Rap. du Congrès International de Physique*, Paris, 1900, vol. ii. p. 536. Also Nagaoka and Jones, *Phil. Mag.* vol. xli. (1896), p. 454. As to the disputed question whether there exists a compressive stress equal to $B^2/8\pi$ or $(B^2 - H^2)/8\pi$, see letters by Chree, Jones, Ewing, and Wilberforce, *Nature*, vol. liii. (1896). Also More, Klingenberg, and Brackett, *loc. cit.*

elaborated by Kirchhoff (*Wied. Ann.* vol. xxiv. (1885), p. 52, and vol. xxv. p. 601), but so far without any great success. Taylor Jones showed in 1897 that only a small proportion of the contraction exhibited by a nickel wire when magnetized could be accounted for on Kirchhoff's theory from the observed effects of pulling stress upon magnetization; and in a more extended series of observations Nagaoka and Honda found wide quantitative divergences between the results of experiment and calculation, though in nearly all cases there was agreement as to quality. They consider, however, that Kirchhoff's theory, which assumes change of magnetization to be simply proportional to strain, is still in its infancy, the present stage of its evolution being perhaps comparable with that reached by the theory of magnetization at the time when the ratio I/H was supposed to be constant. In the light of future researches further development may reasonably be expected.

EFFECTS OF MECHANICAL STRESS UPON MAGNETIZATION.

Certain effects of traction, compression, and torsion in relation to magnetism have been noticed in *Ency. Brit.* vol. xv. pp. 269–271. Since the publication of the ninth edition, the behaviour of the magnetic metals under various kinds of stress has formed the subject of much patient investigation, especially at the hands of Ewing, Nagaoka, and Knott. The results of their experiments embrace a multiplicity of details of which it is impossible to give a brief summary. Only a few of the most important can be mentioned here; the reader who wishes for fuller information should consult the original papers.²

It was first discovered by Villari in 1868 that the magnetic susceptibility of an iron wire was increased by stretching when the magnetization was below a certain value, but diminished when that value was exceeded; this phenomenon has been termed the "Villari reversal," and the value of the magnetization for which stretching by a given load produces no effect is known as the "Villari critical point" for that load. The Villari critical point for a given sample of iron is reached with a smaller magnetizing force when the stretching load is great than when it is small; the reversal also occurs with smaller loads and with weaker fields when the iron is soft than when it is hard. The following table shows the values of I and H corresponding to the Villari critical point in some of Ewing's experiments:—

Soft Iron.			Hard Iron.		
Kilos per sq. mm.	I.	H.	Kilos per sq. mm.	I.	H.
2.15	1220	7.3	27.6	1180	34
4.3	1040	4.3	32.2	1150	32
8.6	840	3.4	37.3	1110	29
12.9	690	3.05	42.5	1020	25

The effects of pulling stress may be observed either when the wire is stretched by a constant load while the magnetizing force is varied, or when the magnetizing force is kept constant while the load is varied. In the latter case the first application of stress is always attended by an increase—often a very great one—of the magnetization, whether the field is weak or strong, but after a load has been put on and taken off several times the changes of magnetization become cyclic. From experiments of both classes it appears that for a given field there is a

² EWING, *Phil. Trans.* vol. clxxvi. (1885), p. 580; vol. clxxxix. (1888), p. 333; *Magnetic Induction* (1900), ch. ix.—EWING and COWAN, *Phil. Trans.* vol. clxxxix. A (1888), p. 325.—NAGAOKA, *Phil. Mag.* vol. xxvii. (1889), p. 117; vol. xxix. (1890), p. 123.—KNOTT, *Trans. R. S. Ed.* vol. xxxii. (1882–83), p. 193; vol. xxxv. (1889), p. 377; vol. xxxvi. (1891), p. 485; *Proc. R. S. Ed.*, 1899, p. 586.—NAGAOKA and HONDA, *Journ. Coll. Sci. Tôkyô*, vol. xiii. part 2 (1900), p. 263.

certain value of the load for which the magnetization is a maximum, the maximum occurring at a smaller load the stronger the field. In very strong fields the maximum may even disappear altogether, the effect of the smallest stress being to diminish the magnetization; on the other hand, with very weak fields the maximum may not have been reached with the greatest load that the wire can support without permanent deformation. When the load on a hardened wire is gradually increased, the maximum value of I is found to correspond with a greater stress than when the load is gradually diminished, this being an effect of hysteresis. Analogous changes are observed in the residual magnetization which remains after the wire has been subjected to fields of different strength. The effects of longitudinal pressure are opposite to those of traction; when the cyclic condition has been reached, pressure reduces the magnetization of iron in weak fields and increases it in strong fields (Ewing, *Magnetic Induction* (1900), p. 223).

The influence of traction in diminishing the susceptibility of nickel was first noticed by Kelvin (Thomson), and has been more recently investigated by Ewing and Cowan. The latter found the effect to be enormous, not only upon the induced magnetization, but in a still greater degree upon the residual. Even under so "moderate" a load as 33 kilogrammes per square mm., the induced magnetization of a hard-drawn nickel wire in a field of 60 fell from 386 to 72 units, while the residual was reduced from about 280 to 10. Ewing has also examined the effects produced by longitudinal compression upon the susceptibility and retentiveness of nickel, and found, as was to be expected, that both were greatly increased by pressure. The maximum susceptibility of one of his bars rose from 5.6 to 29 under a stress of 19.8 kilos per square mm. There were reasons for believing that no Villari reversal would be found in nickel. Ewing and Cowan looked carefully for it, especially in weak fields, but failed to discover anything of the kind.¹ In some experiments by Heydweiller (*Wied. Ann.* vol. lii. (1894), p. 462, and *Electrician*, vol. xxxiv. p. 143) the magnetization of a nickel wire in weak fields (corresponding to $I=5$ or thereabouts) was first diminished and then augmented under increasing tensile stress; but since a cyclic condition does not appear to have been even approximately established before the observations were made, they can hardly be regarded as demonstrating a true Villari effect. Nagaoka and Honda (*Phil. Mag.* vol. xlvi. (1898), p. 26) found that the magnetization of a nickel rod under feeble pulling stress was increased by a little more than half a unit in a weak field. The loads applied were equal to 0.19 and 0.38 kilogramme per square mm., the smallest employed by Ewing having been 5.5. If, therefore, a Villari reversal does occur in the case of nickel, the phenomenon is a very inconspicuous one.

The effects of longitudinal pressure upon the magnetization of cobalt have been examined by Chree (*Phil. Trans.* vol. clxxxi. (1890), p. 329) and also by Ewing (*Magnetic Induction* (1892), p. 210). Chree's experiments were undertaken at the suggestion of J. J. Thomson, who, from the results of Bidwell's observations on the magnetic deformation of cobalt, was led to expect that that metal would exhibit a Villari reversal opposite in character to that observed in iron. The anticipated reversal was duly found by Chree, the critical point corresponding, under the moderate stress employed, to a field of about 120 units.

¹ Tomlinson found a critical point in the "temporary magnetization" of nickel (*Proc. Phys. Soc.* vol. x. (1890), pp. 367, 445), but this does not correspond to a Villari reversal. Its nature is made clear by Ewing and Cowan's curves (*Phil. Trans.* vol. clxxix. (1888), places 15, 16).

Ewing's independent experiments showed that the magnetization curve for a cobalt rod under a load of 16.2 kilos per square mm. crossed the curve for the same rod when not loaded at $H=53$. Both observers noticed analogous effects in the residual magnetization. Meyer (*Wied. Ann.* vol. lix. (1896), p. 134) appears to have found a Villari effect of the opposite sign in feebly magnetized cobalt under pulling stress ($I=3.64$).

It has been shown by J. J. Thomson (*Applications of Dynamics to Physics and Chemistry*, p. 47) that on dynamical principles there must be a reciprocal relation between the changes of dimensions produced by magnetization and the changes of magnetization attending mechanical strain. Since, for example, stretching diminishes the magnetization of nickel, it follows from theory that the length of a nickel rod should be diminished by magnetization and conversely. So, too, the Villari reversals in iron and cobalt might have been predicted—as indeed that in cobalt actually was—from a knowledge of the changes of length which those metals exhibit when magnetized.²

Nagaoka and Honda (*Phil. Mag.* vol. xlvi. (1898), p. 261) have investigated the effects of hydrostatic pressure upon magnetization, using the same pieces of iron and nickel as were employed in their experiments upon magnetic change of volume. In the iron cylinder and ovoid, which expanded when magnetized, compression caused a diminution of magnetization; in the nickel rod, which contracted when magnetized, pressure was attended by an increase of magnetization. The amount of the change was in both cases exceedingly small, that in iron being less than 0.1 C.G.S. unit with a pressure of 250 atmospheres and $H=54$. It would hardly be safe to generalize from these observations; the effects may possibly be dependent upon the physical condition of the metals. In the same paper Nagaoka and Honda describe an important experiment on the effect of transverse stress. An iron tube, having its ends closed by brass caps, was placed inside a compressing vessel into which water was forced until the pressure upon the outer surface of the tube reached 250 atmospheres. The experiment was the reverse of that made by Kelvin with a gun-barrel (*Ency. Brit.* vol. xv. p. 269), and the results were also the reverse. Under increasing magnetizing force the magnetization first increased, reached a maximum, and then diminished until its value ultimately became less than when the iron was in the unstrained condition.

The relations between torsion and magnetization have been discussed in *Ency. Brit.* vol. xv. p. 270. Some of the curious phenomena there referred to are direct consequences of the known effects of longitudinal stress upon magnetization and of magnetization upon form. An explanation due to Maxwell (*Electricity and Magnetism*, § 448) is given of the fact discovered by G. Wiedemann, that if an electric current is passed through a longitudinally magnetized iron wire which is fixed at one end and free at the other, the free end twists in a certain direction. According to Maxwell, the wire becomes helically magnetized, and the expansion of the iron along the lines of magnetization causes the twist. This explanation was not accepted by Wiedemann (*Phil. Mag.*, July 1886, p. 50), who thought the effect was to be accounted for by molecular friction. Now nickel contracts instead of lengthening when it is magnetized longitudinally, and an experiment made by Knott showed, as he expected, that *ceteris paribus* a nickel wire twists in a sense opposite to that in which iron twists. Further, although iron lengthens in fields of moderate strength, it contracts in strong ones; and if the wire is stretched, contraction occurs with smaller magnetizing forces than when it is unstretched. Bidwell (*Phil. Mag.*, September 1886, p. 251) accordingly found upon trial that the Wiedemann twist of an iron wire vanished when the magnetizing force reached a certain rather high value, and was reversed when that value was exceeded; he also found that the vanishing point was reached with lower

² In *Ency. Brit.* vol. xv. p. 271, the first footnote is equivalent to a prediction of the changes of length in magnetized iron which were afterwards observed.

values of the magnetizing force when the wire was stretched by a weight. These observations have been verified and extended by Knott, who has also studied the effect in cobalt, and has brought to light a large number of additional facts, all of which are in perfect harmony with Maxwell's explanation of the twist.

More experiments have been made by Ewing,¹ Knott,² Zehuder,³ and Nagaoka,⁴ on the polarity developed in a circularly magnetized wire by torsion, and on the transient electric currents, indicative of circular magnetization, induced when a longitudinally magnetized wire is twisted; it is noteworthy that both these effects have opposite directions in iron and in nickel. The effects of magnetization upon the torsion of a previously twisted wire have been further studied by F. J. Smith⁵ and by Moreau.⁶ Nagaoka⁷ has described the remarkable influence of combined torsion and tension upon the susceptibility of nickel, and has made the extraordinary observation that, under certain conditions of stress, the magnetization of a nickel wire may have a direction opposite to that of the magnetizing force. It is not easy to co-ordinate these results with any other known phenomena of magnetism.

The mutual relations between torsion and magnetization in iron and nickel wires have recently been investigated by Nagaoka and Honda, who have succeeded in showing that all the experimental results contained in the following parallel statements are in qualitative agreement with an extension of Kirchhoff's theory:—

Strains produced by Magnetization.

(1) A longitudinally magnetized wire is twisted by circular magnetization.

(2) A circularly magnetized wire is twisted by longitudinal magnetization.

(3) Up to moderate fields, the twist produced by the longitudinal and circular magnetizations of an iron wire is opposite to that in nickel.

(4) The twist due to longitudinal magnetization of a circularly magnetized iron or nickel wire reaches a maximum in low fields.

(5) In strong fields the twist due to longitudinal magnetization of a circularly magnetized iron wire is reversed and takes place in the same direction as in nickel.

Effects of Stress on Magnetization.

(i.) Twisting a longitudinally magnetized wire gives rise to circular magnetization.

(ii.) Twisting a circularly magnetized wire gives rise to longitudinal magnetization.

(iii.) Up to moderate fields, the transient current (due to circular magnetization) or the longitudinal magnetization produced by twisting a longitudinally or circularly magnetized iron wire respectively, is opposite to that in nickel.

(iv.) The transient current produced by twisting a longitudinally magnetized iron or nickel wire reaches a maximum in low fields.

(v.) In strong fields the direction of the transient current produced by twisting a longitudinally magnetized iron wire is reversed and is in the same direction as in nickel.

EFFECTS OF TEMPERATURE UPON MAGNETISM.

High Temperature.—It has long been known that iron, when raised to a certain "critical temperature" corresponding to dull red heat, loses its susceptibility and becomes magnetically indifferent, or, more accurately, is transformed from a ferromagnetic into a paramagnetic body. Recent researches have shown that other important changes in its properties occur at the same critical temperature. Abrupt alterations take place in its specific heat, thermo-electric quality, electrical conductivity, temperature-coefficient of electrical resistance, and in some at least of its mechanical properties. Ordinary magnetizable iron is in many respects an essentially different substance from the non-magnetizable metal into which it is transformed when its temperature is raised above a certain point (see *Brit. Assoc. Report*, 1890, p. 145). The first exact experiments demonstrating the changes which occur in the permeability of iron, steel, and nickel when heated up to high temperatures were those of Hopkinson (*Phil.*

Trans. vol. clxxx. (1889), p. 443; *Proc. Roy. Soc.* vol. xlv. (1888), p. 317). The metal to be tested was prepared in the form of a ring, upon which were wound primary and secondary coils of copper wire insulated with asbestos. The primary coil carried the magnetizing current; the secondary, which was wound inside the other, could be connected either with a ballistic galvanometer for determining the induction, or with a Wheatstone's bridge for measuring the resistance, whence the temperature was calculated. The ring thus prepared was placed in a cast-iron box and heated in a gas furnace. The following are the chief results of Hopkinson's experiments: For small magnetizing forces the magnetization of iron steadily increases with rise of temperature till the critical temperature is approached, when the rate of increase becomes very high, the permeability in some cases attaining a value of about 11,000; the magnetization then with remarkable suddenness almost entirely disappears, the permeability falling to about 1.14. For strong magnetizing forces (which in these experiments did not exceed $H = 48.9$) the permeability remains almost constant at its initial value (about 400), until the temperature is within nearly 100° of the critical point; then the permeability diminishes more and more rapidly until the critical point is reached and the magnetization vanishes. Steel behaves in a similar manner, but the maximum permeability is not so high as in iron, and the fall, when the critical point is approached, is less abrupt. The critical temperature for various samples of iron and steel ranges from 690° C. to 870° C.; it is the temperature at which Barrett's "recalescence" occurs. The critical temperature for the specimen of nickel examined (which contained nearly 5 per cent. of impurities) was 310° C. Lydall and Pocklington found that the critical temperature of nearly pure iron was 874° C. (*Proc. Roy. Soc.* vol. lii. (1893), p. 228).

An exhaustive research into the effects of heating on the magnetic properties of iron has been carried out by D. K. Morris (*Proc. Phys. Soc.* vol. xv. (1897), p. 134; and *Phil. Mag.* vol. xlv. (1897), p. 213), the results being embodied in a paper containing twelve pages of tables and upwards of 120 curves. As in Hopkinson's experiments, ring magnets were employed; these were wound with primary and secondary coils of insulated platinum wire, which would bear a much higher temperature than copper without oxidation or fusion. A third platinum coil, wound non-inductively between the primary and the secondary, served to carry the current by which the ring was heated; a current of 4.6 amperes, with 16 volts across the terminals, was found sufficient to maintain the ring at a temperature of 1150° C. In the ring itself was embedded a platinum-thermometer wire, from the resistance of which the temperature was determined. The whole was wrapped in several coverings of asbestos and placed in a glass vessel from which the air was partially exhausted, additional precautions being taken to guard against oxidation of the iron.

Some preliminary experiments showed the striking difference in the effects of annealing at a red heat (840° C.) and at a low white heat (1150° C.). After one of the rings had been annealed at 840° , its maximum permeability at ordinary temperatures was 4000 for $H = 1.84$; when it had been subsequently annealed at 1150° , the maximum permeability rose to 4680 for $H = 1.43$, while the hysteresis loss for $B = \pm 4000$ was under 500 ergs per ccm. As regards the effects of temperature, Morris's results are in general agreement with those of Hopkinson, though no doubt they indicate details with greater clearness and accuracy. Specimens of curves showing the relation of induction to magnetic field at various temperatures, and of permeability to temperature with fields of different intensities, are given in Figs. 22 and 23. The most striking feature presented by these is the enormous value, 12,660, which, with $H = 0.153$, is attained by the permeability at 765° C., followed by a drop so precipitous that when the temperature is only 15° higher, the value of the permeability has become quite insignificant. The critical

temperatures for three different specimens of iron were 795°, 780°, and 770° respectively. Above these temperatures the little permeability that remained was found to be independent of the magnetizing

Fig. 22.

force, but it appeared to vary a little with the temperature, one specimen showing a permeability of 100 at 820°, 2.3 at 950°, and 17 at 1050°. These last observations are, however, regarded as

Fig. 23.

uncertain. The effects of temperature upon hysteresis were also carefully studied, and many hysteresis loops were plotted. The results of a typical experiment are given in the annexed table, which shows how greatly the hysteresis loss is diminished as the critical temperature is approached. The coercive force at 764.5° is stated to have been little more than 0.1 C.G.S. unit; above the critical temperature no evidence of hysteresis could be obtained.

Hysteresis Loss in Ergs per ccm.		Max. H = ± 6.83.

Low Temperature.—Fleming and Dewar (*Proc. Roy. Soc.* vol. lx. (1896), p. 81) have conducted a unique series of experiments on the permeability and hysteresis of iron at low temperatures down to that of liquid air (−186° C.). Induction curves of an annealed soft-iron ring were taken first at a temperature of 15° C., and afterwards when the ring was immersed in liquid air, the magnetizing force ranging from about 0.8 to 22. After this operation had been repeated a few times, the iron was found to have acquired a stable condition, and the curves corresponding to the two temperatures became perfectly definite. They showed that the permeability of this sample of iron was considerably diminished at the lower temperature. The maximum permeability (for H = 2) was 3400 at 15°, and only 2700 at −186°, a reduction of more than 20 per cent.; but the percentage reduction became less as the magnetizing force departed from the value corresponding to maximum permeability. Observations were also made of the changes of permeability which took place as the temperature of the sample slowly rose from −186° to 15°, the magnetizing force being kept constant throughout an experiment. The values of the permeability corresponding to the highest and lowest temperatures are given in the following table. Most of the permeability-temperature

Sample of Iron.	H.	μ at 15°.	μ at −186°.
Annealed Swedish	1.77	2835	2332
Unannealed „	1.78	917	1272
„ „	9.79	1210	1293
Hardened „	2.66	56	132

„ „	127.7	109	124
Steel wire	7.50	86	64.5
„	20.39	361	144

curves were more or less convex towards the axis of temperature, and in all the experiments, except those with annealed iron and steel wire, the permeability was greatest at the lowest temperature.⁷ The hysteresis of the soft annealed iron turned out to be sensibly the same for equal values of the induction at −186° as at 15°, the loss in ergs per ccm. per cycle being approximately represented by 0.002B^{1.56} when the maximum limits of B were ± 9000. Experiments with the sample of unannealed iron failed to give satisfactory results, owing to the fact that no constant magnetic condition could be obtained.

Permanent Magnets.—The same experimenters (*loc. cit.* p. 57) also investigated the changes which occurred in permanently magnetized metals when cooled to the temperature of liquid air. The metals, which were prepared in the form of small rods, were magnetized between the poles of an electromagnet and tested with a magnetometer at temperatures of −186° and 5°. The first immersion into liquid air generally produced a permanent decrease of magnetic moment, and there was sometimes a further decrease when the metal was warmed up again; but after a few alternations of temperature the changes of moment became definite and cyclic. When the permanent magnetic condition had been thus established, it was found that in the case of all the metals, except the two alloys containing large percentages of nickel, the magnetic moment was temporarily increased by cooling to −186°. The following table shows the principal results. It is suggested that a permanent magnet might conveniently be “aged” (or brought into a constant condition) by dipping it several times into liquid air.

⁷ Thiessen (*Phys. Rev.* vol. viii. (1899), p. 65) and Claude (*C. R.* vol. cxxix. (1899), p. 409) found that for considerable inductions (B = 15,000) the permeability and hysteresis-loss remained nearly constant down to −186°; for weak inductions both notably diminished with temperature.

Metal.	Percentage Gain or Loss of Moment at -186° C.	
	First Effect.	Cyclic Effect.

„ „ 1 per cent.	„	+12

Other experiments relating to the effect of temperature upon permanent magnets have been carried out by Ashworth,¹ who showed that the temperature coefficient of permanent magnets might be reduced to zero (for moderate ranges of temperature) by suitable adjustment of temper and dimension ratio; also by Pictet² and by Durward.³

Alloys of Nickel and Iron.—A most remarkable effect of temperature was discovered by Hopkinson (*Proc. Roy. Soc.* vol. xlvii. (1890), p. 23; vol. xlviii. (1891), p. 1) in 1889. An alloy containing about 3 parts of iron and 1 of nickel—both strongly magnetic metals—is under ordinary conditions practically non-magnetizable ($\mu=1\cdot4$ for any value of H). If, however, this non-magnetic substance is cooled to a temperature a few degrees below freezing-point, it becomes as strongly magnetic as average cast-iron ($\mu=62$ for $H=40$), and retains its magnetic properties indefinitely at ordinary temperatures. But if the alloy is heated up to 580° C., it loses its susceptibility—rather suddenly when H is weak, more gradually when H is strong—and remains non-magnetizable till it is once more cooled down below the freezing-point. This material can therefore exist in either of two perfectly stable conditions, in one of which it is magnetizable, while in the other it is not. When magnetizable, it is a hard steel, having a specific electrical resistance of 0'000052; when non-magnetizable, it is an extremely soft, mild steel, and its specific resistance is 0'000072. Alloys containing different proportions of nickel were found to exhibit the phenomenon, but the two critical temperatures were less widely separated. The following approximate figures are deduced from Hopkinson's curves:—

Percentage of Nickel.	Susceptibility lost at temp. C.	Susceptibility gained at temp. C.
0'97	890	—
4'7	820	660
4'7	780	600
24'5	680	-10
30'0	140	125
33'0	207	193
73'0	202	202

Guillaume⁴ has further investigated the properties of nickel-steels, and found that the temperature at which magnetic susceptibility is recovered is lowered by the presence of chromium; a certain nickel-chromium alloy was not rendered magnetic even by immersion in liquid air. Experiments on the subject have also been carried out by Dumont⁵ and Osmond.⁶

ALLOYS AND COMPOUNDS OF IRON.

In 1885 Hopkinson (*Phil. Trans.* vol. clxxvi. (1885), p. 455) employed his yoke method to test the magnetic properties of thirty-five samples of iron and steel, among

⁶ *Ibid.* vol. cxxviii. (1899), pp. 304, 1395.

which were steels containing substantial proportions of manganese, silicon, chromium, and tungsten. The results, together with the chemical analysis of each sample, are given in a table contained in his paper, some of them being also represented graphically. The most striking phenomenon which they bring into prominence is the effect of any considerable quantity of manganese in annihilating the magnetic property of iron. A sample of Hadfield's manufacture, containing 12'36 per cent. of manganese, differed hardly at all from a non-magnetic substance, its permeability being only 1'27. According to Hopkinson's calculation, this sample behaved as if 91 per cent. of the iron contained in it had completely lost its magnetic property.⁷ Another point to which attention is directed is the exceptionally great effect which hardening has upon the magnetic properties of chrome steel; one specimen had a coercive force of 9 when annealed, and of no less than 38 when oil-hardened. The effect of the addition of tungsten in increasing the coercive force is very clearly shown; in two specimens containing respectively 3'44 and 2'35 per cent. of tungsten the coercive force was 64'5 and 70'7. These high values render hardened tungsten-steel particularly suitable for the manufacture of permanent magnets. Hopkinson (*Proc. Roy. Soc.* vol. xlviii. (1890), p. 1) also noticed some peculiarities of an unexpected nature in the magnetic properties of the nickel-steel alloys already referred to. The permeability of the alloys containing from 1 to 4'7 per cent. of nickel, though less than that of good soft iron for magnetizing forces up to about 20 or 30, was greater for higher forces, the induction reached in a field of 240 being nearly 21,700. The induction for considerable forces was found to be greater in a steel containing 73 per cent. of nickel than in one with only 33 per cent., though the permeability of pure nickel is much less than that of iron.

The magnetic qualities of various alloys of iron have been submitted to a very complete examination by Barrett, Brown, and Hadfield (*Trans. Roy. Dub. Soc.* vol. vii. (1900), p. 67; *Journ. Inst. Elec. Eng.*, 1902).⁸ More than fifty different specimens were tested, most of which contained a known proportion of manganese, nickel, tungsten, aluminium, chromium, copper, or silicon; in some samples two of the substances named were present. Of the very numerous results published, a few of the most characteristic are collected in the following table. The first column contains the symbols of the various elements which were added to the iron, and the second the percentage proportion in which each element was present; the sample containing 0'03 per cent. of carbon was a specimen of the best commercial iron, the values obtained for it being given for comparison. All the metals were annealed.

Element.	Per Cent.	B for H=45.	B residual.	μ for H=8.	Coercive Force.
C	0'03	16800	9770	1625	1'66

Si	5'5	15980	3430	1630	0'85

⁷ See also Hopkinson, *Journ. Inst. Elect. Eng.* vol. xix. p. 20, and Ewing, *Phil. Trans.* vol. clxxx. (1889), p. 239.

⁸ Many of the figures which, through an error, were inaccurately stated in the first paper are corrected in the second.

A few among several interesting points should be specially noticed. The addition of 15.2 per cent. of manganese produced an enormous effect upon the magnetism of iron, while the presence of only 2.25 per cent. was comparatively unimportant. When nickel was added to the iron in increasing quantities, the coercive force increased until the proportion of nickel reached 20 per cent.; then it diminished, and when the proportion of nickel was 32 per cent. the coercive force had fallen to the exceedingly low value of 0.5. In the case of iron containing 7.5 per cent. of tungsten (W), the residual induction had a remarkably high value; the coercive force, however, was not very great. The addition of silicon in small quantities considerably diminished permeability and increased coercive force; but when the proportion amounted to 2.5 per cent. the maximum permeability ($\mu=6100$ for $H=2$) was greater than that of the nearly pure iron used for comparison, while the coercive force was only 0.9.¹ A small percentage of aluminium produced still higher permeability ($\mu=6000$ for $H=2$), the induction in fields up to 60 being greater than in any other known substance, and the hysteresis-loss for moderate limits of B far less than in the purest commercial iron. Certain non-magnetizable alloys of nickel, chromium-nickel, and chromium-manganese were rendered magnetizable by annealing.

A number of iron alloys have been examined by Mme. Sklodowska-Curie (*Bull. Soc. d'Encouragement*, 1898, pp. 36-76), chiefly with the object of determining their suitability for the construction of permanent magnets. Her tests appear to show that molybdenum is even more effective than tungsten in augmenting the coercive force, the highest values observed being 70 to 74 for tungsten-steel, and 80 to 85 for steel containing 3.5 to 4 per cent. of molybdenum. For additional information regarding the composition and qualities of permanent magnet steels, reference may be made to the publications cited below.² Useful instructions have been furnished by Barus (*Terrestrial Magnetism*, vol. ii. (1897), p. 11) for the preparation of magnets calculated to withstand the effects of time, percussion, and ordinary temperature variations. The metal, having first been uniformly tempered glass-hard, should be annealed in steam at 100° C. for twenty or thirty hours; it should then be magnetized to saturation, and finally "aged" by a second immersion in steam for about five hours.

MISCELLANEOUS EFFECTS OF MAGNETIZATION.

Electrical Conductivity.—The specific resistance of many electric conductors is known to be temporarily changed by the action of a magnetic field, but except in the case of bismuth the effect is very small.

Gray and T. Jones (*Proc. Roy. Soc.* vol. lxxvii. (1900), p. 208) found that the resistance of a soft iron wire was increased by about 1/700 in a field of 320 C.G.S. units. The effect appeared to be closely connected with the intensity of magnetization, being approximately proportional to I^4 . Barlow (*Proc. Roy. Soc.*, 1902), experimenting with wires of iron, steel, and nickel, showed that the change of resistance was proportional to a function $aI^2 + bI^4 + cI^6$, where a , b , and c are constants for each specimen. Tomlinson (*Phil. Trans.*, Part I., 1883, p. 153) discovered in 1881 that the resistance of a bismuth rod was slightly increased when the rod was subjected to longitudinal magnetic force, and a year or two later Righi (*Atti R. A. Lincei* [3], vol. xix. p. 545) showed that a more considerable alteration was produced when the magnetic force was applied transversely to the bismuth conductor; he also noticed that the effect was largely dependent upon temperature. (See also Lenard, *Wied. Ann.* vol. xxxix. (1890), p. 619.) The most complete series of experiments yet made on the influence of magnetic force at different temperatures are those of Henderson and of Dewar and Fleming. Henderson (*Phil. Mag.* vol. xxxviii. p. 488) used a little spiral of the pure electrolytic bismuth wire prepared by Hartmann and Braun; this was placed between the pole-pieces of an electromagnet and subjected to fields of various strengths up to nearly 39,000 units. At constant temperature the

¹ The marked effect of silicon in increasing the permeability of cast iron has also been noticed by Caldwell, *Elect. World*, vol. xxxii. (1898), p. 619.

² TROWBRIDGE and SHELDON, *Phil. Mag.* vol. xxix. (1890), p. 136. —PREECE, *Journ. Inst. Elect. Eng.* (1890), p. 62; also *Electrician*, vol. xxv. (1890), p. 546. —KLEMENCIC, *Wien. Ber.* vol. cv. 11a. (1896), p. 635. —PEIRCE, *Am. Journ. Sci.* vol. ii. (1896), p. 347. —AET, *Wied. Ann.* vol. lxxvi. (1898), p. 116. —OSMOND, *C. R. vol. cxxviii.* (1899), p. 1513.

resistance increased with the field; the changes in the resistance of the spiral when the temperature was 18° C. are indicated in the annexed table, from which it will be seen that in the strongest

H.	R.	H.	R.
0	1.000	27450	2.540
6310	1.253	32730	2.846
12500	1.630	38900	3.334
20450	2.160		

transverse field reached the resistance was increased more than threefold. Other experiments showed the relation of resistance to temperature (from 0° to about 90°) in different constant fields. It appears that as the temperature rises the resistance decreases to a minimum and then increases, the minimum point occurring at a higher temperature the stronger the field. For $H=11,500$ the temperature of minimum resistance was about 50°; for much lower or higher values of H the actual minimum did not occur within the range of temperature dealt with. Dewar and Fleming (*Proc. Roy. Soc.* vol. lx. p. 425) worked with a similar specimen of bismuth, and their results for a constant temperature of 19° agree well with those of Henderson. They also experimented with constant temperatures of -79°, -185°, and -203°, and found that at these low temperatures the effect of magnetization was enormously increased. The following table gives some of their results, the specific resistance of the bismuth being expressed in C.G.S. units.

Field Strength.	Temp. 19° C.		Temp. -185° C.	
	Spec. Res.	Comp. Res.	Spec. Res.	Comp. Res.
0	116200	1.000	41000	1.00
1375	118200	1.017	103300	2.52
2750	123000	1.059	191500	4.67
8800	149200	1.284	738000	18.0
14150	186200	1.602	1730000	42.2
21800	257000	2.212	6190000	151

At the temperature of liquid air (-185°) the application of a field of 21,800 multiplied the resistance of the bismuth no less than 150 times. Fig. 24 shows the variations of resistance in relation to

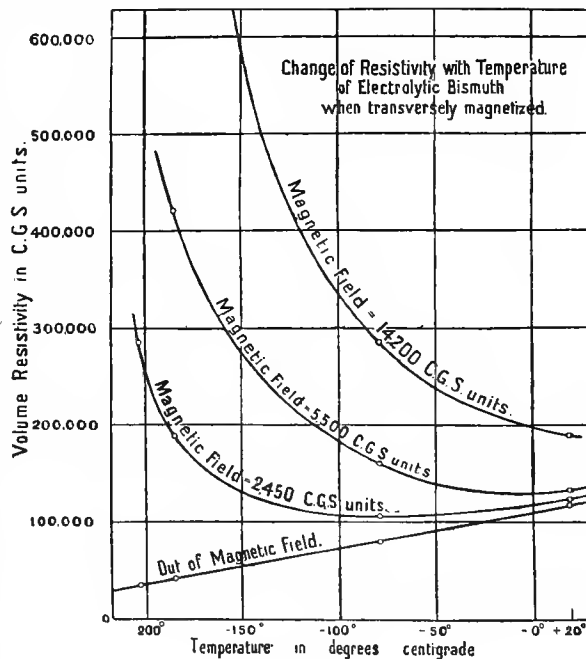

Fig. 24.

temperature for fields of different constant values. It will be seen that for $H=2450$ and $H=5500$ the minimum resistance occurs at temperatures of about -80° and -7° respectively.

Hall Effect.—If an electric current is passed along a strip of thin metal, and the two points at opposite ends of an equipotential line are connected with a galvanometer, its needle will of course not be deflected. But the application of a magnetic field at right angles to the plane of the metal causes the equipotential lines to rotate through a small angle, and the points at which the galvanometer is connected being no longer at the same

potential, a current is indicated by the galvanometer. (See *Ency. Brit.* vol. xv. p. 273.) The transverse electromotive force is equal to KCH/D , where C is the current, H the strength of the field, D the thickness of the metal, and K a constant which has been termed the *rotatory power* or *rotational coefficient*. (See Hopkinson, *Phil. Mag.* vol. x. (1880), p. 430.) The following values of K for different metals are given by Hall (*Phil. Mag.* vol. xix. (1885), p. 419), the positive sign indicating that the electromotive force is in the same direction as the mechanical force acting upon the conductor. Ettinghausen

Metal.	$K \times 10^{15}$.	Metal.	$K \times 10^{15}$.
Antimony	+114000	Copper	-520
Steel	+12060	Gold	-660
Iron	+7850	Nickel	-14740
Cobalt	+2460	Bismuth ¹	-8580000
Zinc	+820		

and Nernst (*Wien. Ber.* vol. xciv. [2] (1886), p. 560) have found that the rotational coefficient of tellurium is more than fifty times greater than that of bismuth, its sign being positive. Several experimenters have endeavoured to find a Hall effect in liquids, but such results as have been hitherto obtained are by no means free from doubt. Marx (*Ann. d. Phys.* vol. ii. (1900), p. 798) observed a well-defined Hall effect in incandescent gases.

Electro-Thermal Relations.—The Hall electromotive force is only one of several so-called “galvano-magnetic effects” which are observed when a magnetic field acts normally upon a thin plate of metal traversed by an electric current. It is remarkable that if a flow of heat be substituted for a current of electricity, a closely allied group of “thermo-magnetic effects” is presented. The two classes of phenomena have been collated by Lloyd (*Am. Journ. Sci.* vol. xii. (1901), p. 57) as follows:—

Galvano-Magnetic Effects.

- (1) A transverse difference of electric potential (Hall effect).
- (2) A transverse difference of temperature (Ettinghausen effect).
- (3) Longitudinal change of electric conductivity.
- (4) Longitudinal difference of temperature.

Thermo-Magnetic Effects.

- (i.) A transverse difference of electric potential (Nernst effect).
- (ii.) A transverse difference of temperature (Leduc effect).
- (iii.) Longitudinal change of thermal conductivity.
- (iv.) Longitudinal difference of electric potential.²

If in the annexed diagram ABCD represents the metallic plate through which the current of electricity or heat flows in the direction AB, then effects (1), (2),

(i.), and (ii.) are exhibited at C and D, effects (4) and (iv.) at A and B, and effects (3) and (iii.) along AB. The transverse effects are reversed in direction when either

the magnetic field or the primary current (electric or thermal) is reversed, but the longitudinal effects are independent of the direction of the field. Bismuth is the only metal in which all the phenomena of both classes have yet been observed. It has been shown by Moreau (*C. R.* vol. cxxx. (1900), pp. 122, 412, 562) that if K is the coefficient of the Hall effect (1) and K' the analogous coefficient of the Nernst effect (i.) (which is constant for small values of H), then $K' = K\sigma/\rho$, σ being the coefficient of the Thomson effect for the metal and ρ its specific resistance. He considers that Hall's is the fundamental phenomenon, and that the Nernst effect is

essentially identical with it, the primary electromotive force in the case of the latter being that of the Thomson effect in the unequally heated metal (*Ency. Brit.* vol. viii. p. 97), while in the Hall experiment it is derived from an external source.

Thermo-electric Quality.—According to Kelvin (Thomson) the thermo-electric quality of iron is affected by longitudinal magnetization in such a manner that the thermo-electric current flows from the unmagnetized to the magnetized metal through the hot junction; or, in other words, longitudinal magnetization renders iron less positive (*Ency. Brit.* vol. xv. p. 273). It has been found that when the magnetizing force is increased, this effect passes a maximum, and in a sufficiently strong field would probably even be reversed.³ Ewing (*Phil. Trans.* vol. clxxvii. p. 373) has shown that tensile stress diminishes the thermo-electric effect of magnetization and reverses it when the load is great; nickel always becomes more positive when magnetized; Tomlinson (*Proc. Roy. Soc.* vol. xxxix. (1885), p. 513) found that cobalt in a magnetic field of 44 units was negative to unmagnetized cobalt. If it should turn out that the effect upon cobalt is reversed in a weak field, the interesting fact would be established that the changes produced by magnetization in the thermo-electric qualities of the ferromagnetic metals are exactly parallel to those which it causes in their dimensions. A comprehensive series of experiments by Lownds (*Ann. d. Phys.* vol. iv. (1901), p. 776) shows conclusively, in opposition to the view long held, that the thermo-electric quality of bismuth is entirely unaffected by a magnetic field.

Elasticity.—The results of experiments as to the effect of magnetization upon elasticity were until quite lately discordant and inconclusive, sufficient care not having generally been taken to protect the specimen under test from the heat radiated by the magnetizing coil. Recent researches, however, indicate pretty clearly that for iron and nickel both Young's modulus and the rigidity are materially increased when the metals are subjected to a magnetic field.⁴ Day, finding that in very strong fields the rigidity continued to increase long after magnetic saturation had been reached, concludes that the phenomena of magnetic intensity and of magnetic rigidity are quite distinct, a practical limit to the former being reached in comparatively weak fields. This observation is of interest in relation to the changes of length produced by magnetism, though, as Barus remarks, the rigidity, unlike the length, never passes a maximum. Tangl's delicate experiments show that Young's modulus for a magnetized wire depends not only upon the magnetizing force, but also upon the tensile stress. The effects are very complex, and require further investigation.

Chemical and Voltaic Effects.—If two iron plates, one of which is magnetized, are immersed in an electrolyte, a current will generally be indicated by a galvanometer connected with the plates.

As to whether the magnetized plate becomes positive or negative to the other, different experimenters are not in agreement. It has, however, been shown by Hurmuzescu (*Rap. du Congrès Int. de Phys.*, Paris, 1900, p. 561) that the true effect of magnetization is liable to be disguised by secondary or parasitic phenomena, arising chiefly from polarization of the electrodes and from local variations in the concentration and magnetic condition of the electrolyte; these may be avoided by working with weak solutions, exposing only a small surface in a non-polar region of the metal, and sub-

¹ The large Hall effect in bismuth was discovered by Righi (*Journ. de Phys.* [2], vol. iii. (1884), p. 127).

stituting a capillary electrometer for the galvanometer generally used. When such precautions are adopted it is found that the "electromotive force of magnetization" is, for a given specimen, perfectly definite both in direction and in magnitude; it is independent of the nature of the corrosive solution, and is a function of the field-strength alone, the curves showing the relation of electromotive force to field-intensity bearing a rough resemblance to the familiar I-H curves. The value of the E.M.F. when $H=2000$ is of the order of $1/100$ volt for iron, $1/1000$ volt for nickel, and $1/10,000$ for bismuth. When the two electrodes are ferromagnetic, the direction of the current through the liquid is from the unmagnetized to the magnetized electrode, the latter being least attacked; with diamagnetic electrodes the reverse is the case. Hurmuzescu shows that these results are in accord with theory. Applying the principle of the conservation of internal energy, he demonstrates that for iron in a field of 1000 units and upwards the E.M.F. of magnetization is

$$E = \frac{l}{\delta} \cdot \frac{I^2}{2\kappa} \quad \text{approximately,}$$

l being the electrochemical equivalent and δ the density of the metal. Owing to the difficulty of determining the magnetization I and the susceptibility κ with accuracy, it has not yet been possible to submit this formula to a quantitative test, but it is said to afford an indication of the results given by actual experiment. It has been discovered by Nichols and Franklin (*Am. Journ. Sci.* vol. xxxiv. (1887), p. 419; vol. xxxv. p. 290) that the transition from the "passive" to the active state (see *Ency. Brit.* vol. xiii. p. 279) of iron immersed in strong nitric acid is facilitated by magnetization, the temperature of transition being lowered. This is attributed to the action of local currents set up between unequally magnetized portions of the iron. Similar results have been obtained by Andrews (*Proc. Roy. Soc.* vol. xlviii. (1890), p. 116).

FEEBLY SUSCEPTIBLE SUBSTANCES.

Water.—The following are recent determinations of the magnetic susceptibility of water:—

Observer.	$\kappa \times 10^6$.	Publication.
Quincke	-0.797 at 18°C .	<i>Wied. Ann.</i> vol. xxiv. p. 387, 1885.
Du Bois	$-0.837 (1 - 0.0025 t - 15^\circ)$	<i>Wied. Ann.</i> vol. xxxv. p. 137, 1888.
Curie	-0.790 at 4°C .	<i>C. R.</i> vol. cxvi. p. 136, 1893.
Townsend	-0.77	<i>Phil. Trans.</i> vol. clxxxvii. p. 544, 1896.
Fleming and Dewar	-0.74	<i>Proc. Roy. Soc.</i> vol. lxiii. p. 311, 1898.
Koenigsberger	-0.803 at 21°C .	<i>Wied. Ann.</i> vol. lxvi. p. 698, 1898.
Jäger and Meyer	$-0.689 (1 - 0.0016t)$	<i>Wied. Ann.</i> vol. lxvii. p. 707, 1899.

Oxygen and Air.—The best modern determinations of the value of κ for gaseous oxygen agree very fairly well with that given by Faraday in 1853. (See *Ency. Brit.* vol. xv. p. 267.) Assuming that for water $\kappa = -0.8 \times 10^{-6}$, his value of κ for oxygen at 15°C . reduces to 0.15×10^{-6} . Important experiments on the susceptibility of oxygen at different pressures and temperatures have been carried out by P. Curie (*C. R.* vol. cxv. p. 805; vol. cxvi. p. 136; *Journ. de Phys.* [3], vol. iv. p. 204). He found that the susceptibility for unit of mass, K , was independent of both pressure and magnetizing force, but varied inversely as the absolute temperature, θ , so that $10^6 K = 33700/\theta$. Since the mass of 1 cub. cm. of oxygen at 0°C . and 760 mm. pressure is 0.00141 grm., the mass at any absolute temperature θ is by Charles's law $0.00141 \times 273/\theta = 0.3849/\theta$ grm.; hence the susceptibility per unit of volume at 760 mm. will be

$$\begin{aligned} \kappa &= 10^{-6} \times 0.3849 \times 33700/\theta^2 \\ &= 10^{-6} \times 12970/\theta^2. \end{aligned}$$

At 15°C . $\theta = 273 + 15 = 288$, and therefore $\kappa = 0.156 \times 10^{-6}$, nearly the same as the value found by Faraday. At 0°C ., $\kappa = 0.174 \times 10^{-6}$. For air Curie calculated that the susceptibility per unit mass was $10^6 K = 7830/\theta$; or, taking the mass of 1 c.c. of air at 0°C . and 760 mm. as

0.001291 grm., $\kappa = 10^{-6} \times 2760/\theta^2$ for air at standard atmospheric pressure. It is pointed out that this formula may be used as a temperature correction in magnetic determinations carried out in air.

Fleming and Dewar determined the susceptibility of liquid oxygen (*Proc. Roy. Soc.* vol. lx. (1896), p. 283; vol. lxiii. p. 311) by two different methods. In the first experiments it was calculated from observations of the mutual induction of two conducting circuits in air and in the liquid; the results for oxygen at -182°C . were

$$\mu = 1.00287, \quad \kappa = 228 \times 10^{-6}.$$

In the second series, to which greater importance is attached, measurements were made of the force exerted in a divergent field upon small balls of copper, silver, and other substances, first when the balls were in air and afterwards when they were immersed in liquid oxygen. If V is the volume of a ball, H the strength of the field at its centre, and κ' its apparent susceptibility, the force in the direction x is $f = \kappa' V H \times dH/dx$; and if κ'_a and κ'_o are the apparent susceptibilities of the same ball in air and in liquid oxygen, $\kappa'_a - \kappa'_o$ is equal to the difference between the susceptibilities of the two media. The susceptibility of air being known—practically it was negligible in these experiments—that of liquid oxygen can at once be found. The mean of 36 experiments with 7 balls gave

$$\mu = 1.00407, \quad \kappa = 324 \times 10^{-6}.$$

A small but decided tendency to a decrease of susceptibility in very strong fields was observed. It appears, therefore, that liquid oxygen is by far the most strongly paramagnetic liquid known, its susceptibility being more than four times greater than that of a saturated solution of ferric chloride. On the other hand, its susceptibility is about 50 times less than that of Hadfield's 12 per cent. manganese steel, which is commonly spoken of as non-magnetizable.

Bismuth.—Bismuth is of special interest, as being the most strongly diamagnetic substance known, the mean value of the seven determinations of its susceptibility given in *Ency. Brit.* vol. xv. p. 268, being -14.6×10^{-6} . The magnetic properties of the metal at different temperatures and in fields up to 1350 units have been studied by P. Curie (*loc. cit.*), who found that its "specific susceptibility" (K) was independent of the strength of the field, but decreased with rise of temperature up to the melting-point, 273°C . His results appear to show the relation

$$-K \times 10^6 = 1.381 - 0.00155t^\circ.$$

Assuming the density of Bi to be 9.8, and neglecting corrections for heat dilatation, his value for the susceptibility at 20°C . is equivalent to $\kappa = -13.23 \times 10^{-6}$. As the temperature was raised up to 273° , κ gradually fell to -9.38×10^{-6} , rising suddenly when fusion occurred to -0.37×10^{-6} , at which value it remained constant when the fluid metal was further heated. Fleming and Dewar give for the susceptibility the values -13.7×10^{-6} at 15°C . and -15.9×10^{-6} at -182° , the latter being approximately equivalent to $K \times 10^6 = -1.62$. Putting $t^\circ = -182$ in the equation given above for Curie's results, we get $K \times 10^6 = -1.66$, a value sufficiently near that obtained by Fleming and Dewar to suggest the probability that the diamagnetic susceptibility varies inversely as the temperature between -182° and the melting-point.

Other Diamagnetics.—The following table gives Curie's determinations (*Journ. de Phys.* vol. iv. (1895), p. 204) of the specific susceptibility K of other diamagnetic substances at different temperatures. It should be noted that $K = \kappa/\text{density}$.

Substance.	Temp. ° C.	-K × 10 ⁶ .
Water	15 - 189	0.790
Rock salt	16 - 455	0.580
Potassium chloride	18 - 465	0.550
" sulphate	17 - 460	0.430
" nitrate (fusion 350°)	18 - 420	0.330
Quartz	18 - 430	0.441
Sulphur, solid or fused	18 - 225	0.510
Selenium, solid or fused	20 - 200	0.320
" fused	240 - 415	0.307
Tellurium	20 - 305	0.311
Bromine	20	0.410
Iodine, solid or fused	18 - 164	0.385
Phosphorus, solid or fused	19 - 71	0.920
" amorphous	20 - 275	0.730
Antimony, electrolytic	20	0.680
"	540	0.470
Bismuth, solid	20	1.350
"	273	0.957
" fused	273 - 405	0.038

For all diamagnetic substances, except antimony and bismuth, the value of K was found to be independent of the temperature.

Paramagnetic Substances.—Experiments by Henderson (*Phil. Trans.* vol. clxxxvii. (1896), p. 533) show that the susceptibility of solutions of salts of iron is independent of the magnetizing force, and depends only on the quantity of iron contained in unit volume of the liquid. If W is the weight of iron present per c.c. at about 10° C., then for ferric salts

$$10^6 \kappa = 266W - 0.77$$

and for ferrous salts

$$10^6 \kappa = 206W - 0.77,$$

the quantity -0.77 arising from the diamagnetism of the water of solution. Annexed are values of 10⁶κ for the different salts examined, w being the weight of the salt

Salt.	10 ⁶ κ + 0.77.	Salt.	10 ⁶ κ + 0.77.
Fe ₂ Cl ₆	91.6w	FeCl ₂	90.8w
Fe ₂ (SO ₄) ₃	74.5w	FeSO ₄	74.9w
Fe ₂ (NO ₃) ₆	61.5w		

per c.c. of the solution. Susceptibility was found to diminish greatly with rise of temperature. According to Jäger and Meyer (*Wien. Akad. Sitz.* vol. cvii. II.a, p. 623, and vol. cvii. II.a, p. 5) the atomic susceptibilities *k* of the metals nickel, chromium, iron, cobalt, and manganese in solutions of their salts are as follows:—

Metal.	k × 10 ⁶ .	Metal.	k × 10 ⁶ .
Ni	4.95 = 2.5 × 2	Co	10.0 = 2.5 × 4
Cr	6.25 = 2.5 × 2.5	Fe(2)	12.5 = 2.5 × 5
Fe(1)	7.5 = 2.5 × 3	Mn	15.0 = 2.5 × 6

Fe(1) is iron contained in FeCl₂ and Fe(2) iron contained in FeSO₄ and Fe₂(NO₃)₆.

Curie has shown, for many paramagnetic bodies, that the specific susceptibility K is inversely proportional to the absolute temperature θ. Du Bois believes this to be an important general law, applicable to the case of every paramagnetic substance, and suggests that the product Kθ should be known as "Curie's constant" for the substance.

Elementary Bodies and Atomic Susceptibility.—Among a large number of substances the susceptibilities of which have been determined by Koenigsberger (*Wied. Ann.* vol. lxvi. (1898), p. 698) are the following elements:—

Element.	κ × 10 ⁶ .	Element.	κ × 10 ⁶ .
Copper	-0.82	Tellurium	-2.10
Silver	-1.51	Graphite	+2
Gold	-3.07	Aluminium	+1.80
Zinc	-0.96	Platinum	+22
Tin	+0.46	Palladium	+50 to 60
Lead	-1.10	Tungsten	+14
Thallium	-4.61	Magnesium	+4
Sulphur	-0.86	Sodium	+2.2
Selenium (red)	-0.50	Potassium	+3.6

In a table accompanying Koenigsberger's paper the elements are arranged upon the periodic system and the atomic susceptibility (product of specific susceptibility into atomic weight) is given for each. It appears that the elements at about the middle of each row are the most strongly paramagnetic; towards the ends of a row the susceptibility decreases, and ultimately becomes negative. Thus a relation between susceptibility and atomic weight is clearly indicated. Tables similarly arranged, but much more complete, have been published by Meyer (*Wied. Ann.* vol. lxxviii. (1899), p. 325, and vol. lxxix, p. 236), whose researches have filled up many previously existing gaps. The values assigned to the atomic susceptibilities of most of the known elements are appended. According to the notation adopted by Meyer the atomic susceptibility *k* = κ × atomic-weight / (density × 1000).

Meyer thinks that the susceptibilities of the metals praseodymium, neodidymium, ytterbium, samarium, gadolinium, and erbium, when obtained in a pure form, will be found to equal or even exceed those of the well-known ferromagnetic metals. Many of their compounds are very strongly magnetic, erbium, for example, in Er₂O₃ being four times as strong as iron in the familiar magnetite or lodestone, Fe₂O₃. The susceptibilities of some hundreds of inorganic compounds have also been determined by the same investigator (*loc. cit.*). Among other recently published researches relating to atomic and molecular magnetism are those of Liebknecht and Wills (*Ann. d. Phys.* vol. i. (1900), p. 178), du Bois and Liebknecht (*ibid.* p. 189), and Meyer (*ibid.* p. 668). An excellent summary of the present state of knowledge regarding the magnetic properties of matter, with many tables and references, has been compiled by du Bois (*Report to the Congrès Int. de Phys.*, Paris, 1900, vol. ii. p. 460).

MOLECULAR THEORY OF MAGNETISM.

According to Weber's theory, the molecules of a ferromagnetic metal are small permanent magnets, the axes of which under ordinary conditions are turned indifferently in every direction, so that no magnetic polarity is exhibited by the metal as a whole; a magnetic force acting upon the metal tends to turn the axes of the little magnets in one direction, and thus the entire piece acquires the properties of a magnet. If, however, the molecules could turn with perfect freedom, it is clear that the smallest magnetizing force would be sufficient to develop the highest possible degree of magnetization, which is of course not the case. Weber therefore supposed each molecule to be acted on by a force tending to preserve it in its original direction, the position actually assumed by the axis being in the direction

¹ Calculated.

of the resultant of this hypothetical force and the applied magnetizing force. Maxwell (*Electricity and Magnetism*, § 444), recognizing that the theory in this form gave no account of residual magnetization, made the further assumption that if the deflection of the axis of the molecule exceeded a certain angle, the axis would not return to its original position when the deflecting force was removed, but would retain a permanent set. Although the amended theory as worked out by Maxwell is in rough agreement with certain leading phenomena of magnetization, it fails to account for many others, and is in some cases at variance with observed facts.

Ewing (*Proc. Roy. Soc.* vol. xlvi. (1890), p. 342) has demonstrated that it is quite unnecessary to assume either the directive force of Weber, the permanent set of Maxwell, or any kind of frictional resistance, the forces by which the molecular magnets are constrained being simply those due to their own mutual attractions and repulsions. The effect of these is beautifully illustrated by a model consisting of a number of little compass needles pivoted on sharp points and grouped near to one another upon a board, which is placed inside a large magnetizing coil. When no current is passing through the coil and the magnetic field is of zero strength, the needles arrange themselves in positions of stable equilibrium under their mutual forces, pointing in many different directions, so that there is no resultant magnetic moment. This represents the condition of the molecules in unmagnetized iron. If now a gradually increasing magnetizing force is applied, the needles at first undergo a stable deflection, giving to the group a small resultant moment which increases uniformly with the force; and if the current is interrupted while the force is still weak, the needles merely return to their initial positions. This illustrates the first stage in the process of magnetization, when the moment is proportional to the field and there is no hysteresis or residual magnetism (see *ante*, p. 436). A somewhat stronger field will deflect many of the needles beyond the limits of stability, causing them to turn round and form new stable combinations, in which the direction assumed by most of them approximates to that of the field. The rearrangement is completed within a comparatively small range of magnetizing force, a rapid increase of the resultant moment being thus brought about. When the field is removed, many of the newly formed combinations are but slightly disturbed, and the group may consequently retain a considerable resultant moment. This corresponds to the second stage of magnetization, in which the susceptibility is large and permanent magnetization is set up. A still stronger magnetizing force has little effect except in causing the direction of the needles to approach still more nearly to that of the field; if the force were infinite, every member of the group would have exactly the same direction, and the greatest possible resultant moment would be reached; this illustrates "magnetic saturation"—the condition approached in the third stage of magnetization. When the strong magnetizing field is gradually diminished to zero and then reversed, the needles pass from one stable position of rest to another through a condition of instability; and if the field is once more reversed, so that the cycle is completed, the needles again pass through a condition of instability before a position of stable equilibrium is regained. Now the unstable movements of the needles are of a mechanically irreversible character; the energy expended in dissociating the members of a combination and placing them in unstable positions assumes the kinetic form when the needles turn over, and is ultimately frittered down into heat. Hence in performing a cycle there is a waste of energy corresponding to what has been termed hysteresis-loss.

Supposing Ewing's hypothesis to be correct, it is clear

that if the magnetization of a piece of iron were reversed by a strong rotating field instead of by a field alternating through zero, the loss of energy by hysteresis should be little or nothing, for the molecules would rotate with the field and no unstable movements would be possible.¹ Some experiments by F. G. Baily (*Phil. Trans.* vol. clxxvii. (1896), p. 715) show that this is actually the case. With small magnetizing forces the hysteresis was indeed somewhat larger than that obtained in an alternating field, probably on account of the molecular changes being forced to take place in one direction only; but at an induction of about 16,000 units in soft iron and 15,000 in hard steel the hysteresis reached a maximum and afterwards rapidly diminished. In one case the hysteresis loss per cubic centimetre per cycle was 16,100 ergs for $B=15,900$, and only 1200 ergs for $B=20,200$, the highest induction obtained in the experiment; possibly it would have vanished before B had reached 21,000.² These experiments prove that actual friction must be almost entirely absent, and, as Baily remarks, the agreement of the results with the previously suggested deduction affords a strong verification of Ewing's form of the molecular theory. Ewing has himself also shown how satisfactorily this theory accords with many other obscure and complicated phenomena, such as those presented by coercive force, differences of magnetic quality, and the effects of vibration, temperature, and stress; while as regards simplicity and freedom from arbitrary assumptions it leaves little to be desired.

The next problem which awaits solution concerns the origin of molecular magnetism. Why is it that the molecules or atoms of iron, nickel, cobalt, and perhaps one or two of the rarer metals, have the properties of little magnets, while those of other substances are magnetic only in an immensely inferior degree, or not at all? Ampère's hypothesis that an electric current constantly circulates around each magnetic molecule (*Encyclopædia Britannica*, vol. viii. p. 76) still holds its ground, though in a somewhat modified form. Rowland, carrying out in 1876 an experiment which had been proposed by Maxwell a few years earlier, showed that a revolving electric charge produced the same magnetic effects as a current, and it has been supposed that molecular magnetism may be due, not to currents in the sense contemplated by Ampère, but to the rapid revolution of electrostatic charges. Such a hypothesis has acquired additional probability from the researches of J. J. Thomson and others. Thomson has demonstrated the existence, under many different conditions, of particles more minute than anything previously known to science. The mass of each is about a thousandth part of that of a hydrogen atom, and with each is indissolubly associated a charge of negative electricity equal in quantity to about 6×10^{-10} C.G.S. electrostatic unit. These particles, which were termed by their discoverer *corpuscles*, are more commonly spoken of as *electrons*,³ the particle thus being identified with the charge which it carries. With every material atom in a neutral condition there is linked, as Thomson believes, one or more detachable corpuscles, the number depending

¹ This deduction from Ewing's theory appears to have been first suggested by J. Swinburne. See *Industries*, 1890, p. 289.

² Beattie (*Phil. Mag.* vol. i. (1901), p. 642) has found similar effects in nickel and cobalt.

³ The charge associated with a corpuscle is the same as that carried by a hydrogen atom. Stoney in 1881 (*Phil. Mag.* vol. xi. p. 387) pointed out that this latter constituted the indivisible "atom of electricity," or natural unit charge; later he proposed (*Trans. Roy. Dub. Soc.* vol. iv. (1891), p. 583) that such unit charge should be called an "electron." The application of this term to Thomson's corpuscle implies, rightly or wrongly, that, notwithstanding its apparent mass, the corpuscle is in fact nothing more than an atom of electricity. The question whether a corpuscle actually has a material gravitating nucleus is undecided.

upon the valency of the atom: if the atom loses a corpuscle, it becomes positively electrified; if it receives additional corpuscles, it is negatively electrified. The process of electric conduction in metals consists in the movement of detached corpuscles, and many other phenomena, both electrical and thermal, can be more or less completely explained by their agency. Attempts have been made to account quantitatively for the magnetic properties of iron and other substances on the supposition that the corpuscles or electrons revolve like satellites in orbits around the atoms with which they are associated. The period of revolution would necessarily be almost evanescent. It has been calculated by Lang (*Ann. d. Phys.* vol. ii. (1900), p. 483) that if the iron atom is regarded as divalent, the electrons must travel at a speed comparable with that of light, completing at the lowest estimate more than a trillion revolutions in a second. Such methods of explaining magnetic phenomena are not free from difficulties, and so far they have failed to give any clear indication of a physical cause for the sharply defined difference which exists between ferromagnetic and other bodies. But though at the time of writing no detailed hypothesis has met with general acceptance, it can hardly be doubted that by further researches upon the lines of those to which reference has been made, much new light will in the near future be thrown upon some of the most obscure problems of magnetism.

Magnetism, Terrestrial.—§ 1. In the earlier volumes of the *Encyclopædia Britannica* Dr Balfour Stewart treated terrestrial magnetism as part of the subject of Meteorology (ninth edition, vol. xvi. p. 159). For brevity his article is distinguished here by the letter S. For the same reason the letters R and T are employed to denote respectively the *Repertorium für Meteorologie*, and the journal *Terrestrial Magnetism*, edited by Dr Bauer.

§ 2. The instruments mentioned in S are still those in most general use, but a variety of new forms have been employed during recent years. Amongst these may be mentioned "earth-inductors," or rotating coils, for determining the inclination by induction methods, magnetometers and magnetographs with small magnets (*Ann. du Bureau Central Météorologique de France*, vol. i. 1884, p. B₅₇, &c.; *Wied. Ann.* vol. xix. p. 130, vol. xxix. p. 47, vol. xl. p. 489, vol. lxiv. p. 735, &c.), and very open scale instruments employed by, amongst others, Kohlrausch (*Wied. Ann.* vol. lx. p. 336, &c.) and Eschenhagen (T, vol. i. 1896, p. 55; *Sitz der k. Preuss. Akad. der Wiss.* 30th July 1896 and 24th June 1897; *Verhand. der Deutschen Physik. Gesellsch.* 1899, p. 147, &c.). Under Wild's auspices a variety of forms of magnetometers and earth-inductors have been used by the Russian magnetic service in field and observatory work, in Arctic regions as well as in temperate climates. A summary of modern magnetic instruments, including earth-inductors, with illustrations of Wild's chief forms, was communicated by Edlmann to the Chicago Meteorological Congress (*Bull. No. 11, Part II., U.S. Dept. of Agriculture*, 1895). The degree of accuracy obtainable with these instruments

as well as with English inclinometers, and many questions relating to the determination of constants, have been discussed by Wild himself (R, vol. viii. No. 7; vol. xvi. No. 2; vol. xvii. No. 6; *Mém. de l'Acad. des Sciences de St Pétersbourg*, vol. xxxiv. No. 11; vol. xxxvi. No. 1; vol. xxxvii. No. 4 and No. 6; vol. xxxviii. No. 3, &c.). Investigations on these and cognate matters have also been published by Kohlrausch (*Wied. Ann.* vol. xv. p. 545; vol. xxii. p. 411; vol. xxxi. p. 609, &c.), Mielberg (R, vol. x. No. 1), Leyst (R, vol. x. Nos. 5 and 11), Mascart (*Ann. du Bureau Central Météorologique*, vol. i. 1890, p. B₁₁₃; *Brit. Assoc. Report* for 1898, p. 741, &c.), Borgen (*Archiv der Deutschen Seewarte*, 1891, No. 2, 1895, No. 5, T. vol. i. p. 176; *Beob. aus dem Mag. Obs. in Wilhelms-haven*, 1899, &c.), Palazzo (*Ann. dell' Ufficio Cent. Met. e Geod. Ital.* vol. xvi. Parte 1, 1894), Chree (*Proc. Roy. Soc.* vol. lxxv. p. 375), and others.

§ 3. At a magnetic observatory provision must be made for accommodating both absolute and self-recording instruments. In the case of the former there must be no artificial disturbance, whether due to **Observatories.** magnets or to electric currents. In the case of the latter a constant source of disturbance, such as the proximity of a fixed magnet of unvarying strength, though objectionable, is not fatal, but it is essential that all variable disturbances should be excluded. As changes of temperature influence magnets, and temperature corrections are difficult to determine accurately, uniformity of temperature greatly facilitates magnetic work. In recently-constructed magnetic chambers, at first-class observatories, every precaution is taken to exclude magnetic materials and to secure uniformity of temperature, and the moments and relative positions of the different magnets are carefully arranged so as to avoid mutual interference. For particulars the reader is referred to descriptions of the magnetic chambers at Pavlovsk, Washington, Potsdam, and Parc St Maur (see report by Ensign Marsh, U.S. Navy; Appendix I. to *Washington Observations for 1887*, U.S. Naval Observatory; T, vol. i. 1896, p. 96, and vol. iii. 1898, p. 1), and to an elaborate description of an ideal building by Wild (T, vol. iv. p. 169, see also p. 153). Of late years the development of electric railways and tramways has complicated the question. With the arrangements customary in electric traction, when the cars are running the effects on delicate magnetic instruments are visible at a distance of several miles. By having properly insulated returns, and taking other precautions, these disturbing effects can probably be so much reduced as to safeguard the usefulness of many existing observatories. These precautionary measures entail, however, some additional expense, and the pecuniary interests concerned are so powerful that the rapid development of an enlightened public opinion is much to be desired. In the meantime several magnetic observatories—e.g., those at Washington, Toronto, Batavia, and Vienna—have been completely upset, and most of those situated near large cities are in imminent danger (T, vol. ii. 1897, p. 125, and vol. iii. 1898, p. 145; *Brit. Assoc. Report* for 1898, p. 758; Edler, *Verhandl. der Deutschen Phys. Gesell.* Jahr. 1899, p. 174, &c.).

§ 4. Magnetic changes are often very abrupt; in half an hour the needle may execute a to-and-fro movement much larger than the mean amplitude of its movement during the day. It is usual to confine measurements of the records from **Records.** magnetographs to exact hours (whether local, Göttingen, or Greenwich time). Consequently a good deal may depend on the precise time of occurrence of large erratic movements. The mean curve of the diurnal variation, for so long a period as a month even, might at certain seasons be considerably affected by accidents of this kind. In extreme cases the trace may go off the photographic sheet, leaving the observer nothing to draw on but his imagination. It has thus long been customary to exclude conspicuously large move-

ments in considering many species of magnetic phenomena, and many authorities have sought to exclude even comparatively small irregular movements. Sabine (S, § 48) proposed to exclude any observed value which differed by more than a certain specified amount from the monthly mean of the element in question for that particular hour. The observations so excluded were pretty numerous, as the limits were usually narrow; they were regarded as disturbed. The so-called *disturbances* were found by Sabine (S, §§ 53-59) and other investigators to occur more frequently at certain seasons of the year and at certain hours of the day than at others; thus their exclusion modified the diurnal inequality curves. In view of the great variation in the number and amplitude of magnetic disturbances from year to year, and from station to station, Sabine's method of treatment is unquestionably arbitrary, as will be obvious from the following facts. In England in the course of a day it is extremely rare to have a range of $1\frac{1}{2}^{\circ}$ in the declination, or of $\cdot 005$ C.G.S. units in the horizontal or vertical components. But in polar regions, as was very fully demonstrated by the international work done during the years 1882-83, larger disturbances are frequent. At the British station, Fort Rae, a range of $11\frac{1}{4}^{\circ}$ was observed one day in the declination, and on ten days in the year the range exceeded 5° . At the German station, Kingua Fjord, the range exceeded 5° on each of seven consecutive days in November, and also on twelve other occasions. At the Finnish station, Sodankylä, the declination range never reached 5° ; but on the other hand the horizontal force range exceeded $\cdot 01$ C.G.S. on fifteen occasions, as against thirteen such occasions at Fort Rae and three at Kingua Fjord. At the Russian station, Ssagyster, on the Lena, the declination range exceeded 5° on only five occasions, and the horizontal force range only once reached $\cdot 01$ C.G.S.; but on the other hand the vertical force range exceeded $0\cdot 1$ on about four days on the average out of five, and on one occasion it attained the enormous value of $\cdot 268$ C.G.S. units.

§ 5. During recent years Sabine's method has been largely abandoned in favour of a suggestion of Wild's to "Quiet" select for each month a few specially quiet or normal days, and to employ these alone for many purposes. Where the time and staff available for reducing the records is limited, this plan has obvious economic advantages. Largely for this reason, two British observatories, Kew and Falmouth, during the decade 1890-1900 confined their attention to quiet days alone. To secure uniformity, the quiet days employed—five a month—were selected at the end of each year by the Astronomer Royal. At some seasons it is exceptional to meet with a day's curve entirely free from sinuosities. At the English observatories, when sinuosities occur on a selected quiet day, the portion of

the curve affected is replaced by a pencil line of continuous curvature drawn freehand. At St Petersburg the smoothing process appears to be much more elaborate. This is not the only side on which the quiet-day system is open to criticism. A comparison of the results from normal (quiet) days and all days (exceptionally large movements alone excluded) between 1873 and 1885 at St Petersburg and Pavlovsk, by Muller (R, vol. xii., No. 8, 1889), showed a systematic difference between the mean annual values of certain of the magnetic elements as calculated from the two sets of data. An examination by Ellis (*Brit. Assoc. Report* for 1898, p. 80) of the Greenwich data for the years 1889 to 1896 presented similar features. Table I. gives the average excesses found in these two researches for the quiet day over the *all-day* means, taken algebraically.

TABLE I.—Differences, Quiet less All-day Means.

Station.	Declination + to West.	Horl. Force. Unit = 1×10^{-6} C.G.S.	Vertical Force. Unit = 1×10^{-6} C.G.S.	Inclination.
St Petersburg	+ 0'·24	+ 32	- 8	·23
Greenwich	+ 0'·08	+ 33	- 9	

In the case of the declination, horizontal force, and inclination, the sign of the difference was the same for every year examined by Muller. The magnitude, however, varied, with a tendency apparently to be largest numerically in years of maximum magnetic disturbance (or sun-spot maxima). Thus the secular changes from year to year, or the mean change for a short period of years, deduced from quiet days only, may differ slightly from those deduced from all days.

§ 6. A second unexpected feature of quiet days was dis-

non-cyclic (*Brit. Assoc. Reports*, 1895, p. 209; and 1896, p. 231). On the average, from 1890 to 1895, the horizontal force at Kew increased 21×10^{-5} C.G.S. units a year, so that its value at the second midnight of an average day exceeded its value at the first midnight by approximately 6×10^{-7} C.G.S. On the average quiet day, however, the horizontal force increased 36×10^{-6} C.G.S. Similar phenomena at Greenwich were discussed by Ellis (*Brit. Assoc. Reports*, 1896, p. 238; and 1898, p. 80), and they are apparent in the records of other observatories, e.g., Falmouth, Parc St Maur (Paris), and Colaba (Bombay), where the Astronomer Royal's quiet days have been tabulated. Table II. gives mean values for the non-cyclic increment during twenty-four hours from midnight to midnight. Declination is taken + to the west, and the unit of force is 1×10^{-6} C.G.S. The data for Kew and Greenwich were given by Chree and Ellis (*l.c.*); those for

Colaba are deduced from *Mag. and Met. Observations made at the Govt. Obs., Bombay* (Appendices to years 1896-97).

As magnetic force is usually measured to 1×10^{-5} C.G.S. unit, and angular movement to 0'.1, non-cyclic changes such as appear in Table II. are far from negligible. The non-cyclic effect would introduce a fictitious element into the diurnal inequality. Chree and Ellis eliminate it on the provisional hypothesis that it takes place uniformly throughout the twenty-four hours. Phenomena closely analogous to, if not identical with, the non-cyclic effect have been detected by van Bemmelen in the case of days near times of large magnetic disturbances (*Meteorologische Zeitschrift*, September 1895).

§ 7. The values of the magnetic elements at any given station are in a state of constant change. Part of the change arises from causes of a periodic character, and of

¹ Calculated from results for horizontal and vertical components in Tables IV. and V.

Fig. 1.

and the position of the year in the sun-spot cycle, and is probably modified by other causes; while the hours at which the maxima and minima occur, though less variable, are by no means constant. It is thus impossible to give more than a general idea of the phenomena as observed at a few representative stations.

Tables III. to VI. give the mean diurnal inequalities of the declination, horizontal and vertical force components, and inclination for one or a series of specified years. Of the stations selected, Jan Mayen was the Austrian polar station. Pavlovsk is close to St Petersburg, and succeeded it as the central Russian magnetic observatory. The data are derived from the official publications of the respective stations, or from special papers as follows:—Jan Mayen (*Die Internationale Polarforschung*, 1882-83; *Die Oesterreichische Polar Station*. . . . *k. Akad. der Wiss.* II. Bd., II. Abth.); St Petersburg-Pavlovsk (Muller, R, vol. xii., No. 8, 1889); Greenwich (Ellis, *Brit. Assoc. Report*, 1898, p. 80); Kew (*Brit. Assoc. Report*, 1895, p. 209, and *Reports of Kew Observatory Cttee.*); Parc St Maur (Monreaux, *Ann. du Bureau Central Météorologique de France* for 1897, p. B₆₅); Tiflis (*Coeb. des Tiflisser Physik. Observatoriums* for years 1893 to 1896); Colaba (*Mag. and Met. Observations, Bombay*, years 1896 and 1897); Batavia (*Observations made at the Mag. and Met. Observatory at Batavia*, App. vol. xvi., for 1893); Mauritius (Meldrum and Claxton, *Magnetical Reductions*, Mauritius, 1899). Data from quiet days only are distinguished by the letter *q*; those from all days (except those of exceptional disturbance) by the letter *a*.

§ 8. The difference between all and quiet days' results, so conspicuous at Jan Mayen in all the elements, is considerable even at Pavlovsk and Greenwich in the case of the vertical force. At some stations the times of occurrence of the maxima, minima, and mean values vary considerably throughout the year. This is more especially true of the declination in tropical stations. In fact, according to Sabine (see S, §§ 42, 43), at a station near the magnetic equator, while the declination diurnal inequality during summer

the periods the solar day is the most conspicuous (cf. S, §§ 36-45, 68, &c.). The amplitude of the diurnal inequality of any magnetic element varies with the season of the year

while the declination diurnal inequality during summer

resembles that of temperate stations in its own hemisphere, the inequality during winter is of the type characteristic of the opposite hemisphere. This is perhaps rather an extreme way of stating the facts. It is true, however, that the contributions to the hourly means from different months may to a considerable extent neutralize one another, and that a more correct idea of the phenomena is obtained by considering the winter and summer months separately. For this reason, winter and summer curves of declination are shown side by side on the left-hand side of Fig. 1. They are based on the results for the years specified in Tables III. to V. The uppermost of the right-hand curves shows the inequality of vertical force at Greenwich from *all* and from *quiet* days. The next curves on the same side show the horizontal force inequalities at Kew during summer and winter, while the remaining curves show the mean annual inequalities of horizontal and vertical force at Batavia and Mauritius. The curves relating to the same element are all drawn to the same scale, and the scales for the horizontal and vertical force inequalities are identical. The hours are counted from midnight, which answers to 0 or 24.

§ 9. Two other methods of illustrating diurnal inequalities may be mentioned. The first, which has been employed by Airy, Lloyd, and others, consists in drawing curves to represent disturbing forces to which the inequalities of declination and horizontal force may be ascribed. Such curves are sometimes

Graphic methods.

Fig. 2.

termed *vector diagrams*. The radius vector, from the origin O, represents the forces in question both in magnitude and direction. The hours to which individual radii refer are marked on the curve. It is immaterial what we take as our initial line, or our rectangular axes, so long as the directions are known. It is desirable to show the geographical meridian as well as the mean magnetic meridian of the station for the epoch dealt with.

Fig. 2 is the vector diagram for Kew at midsummer (June and July) for quiet days during 1890-94 (*Brit. Assoc. Report* for 1895). Fig. 3 refers to all, Fig. 4 to quiet days in May to July of 1883 at Jan Mayen, the Austrian polar station. The data on which they are based are given by Lüdeling (*Sitz. der k. Preuss. Akad. der Wiss.* 1893, p. 524; and 1899, p. 236). In the diagrams MM represents the magnetic meridian. As shown by the arrows, Fig. 2 is described in the direction of the hands of a watch—the normal direction in temperate latitudes, both for all and for quiet days. The quiet-day diagram at Jan Mayen is also mainly described clock-

wise (Fig. 4), but the all-day diagram is described anti-clockwise (Fig. 3). Lüdeling found this peculiar difference between all and quiet days to be common to the other polar stations excepting Kingua Fjord, where both diagrams were described clockwise. Lüdeling has also employed vector diagrams to represent the *difference* between the diurnal variations in all and in quiet days at the polar stations; here again the diagrams are described anti-clockwise, except that for Kingua Fjord.

The other graphical method is closely analogous to Bauer's method of showing secular change, illustrated by

Fig. 3.

Fig. 5. Starting with an imaginary needle freely suspended by its centre of gravity, it combines the diurnal changes of declination and inclination in a curve traced on the plane perpendicular to the mean position of the needle. This method has been employed by Rücker ("Rede Lecture," *Nature*, vol. lvii. pp. 160 and 180), and by Capello (*Brit. Assoc. Report* for 1898, p. 750). Capello

Fig. 4.

gives curves for St Petersburg, Kew, Paris, Perpignan, and Lisbon. In the case of the first three mentioned stations the motion is wholly clockwise. The Perpignan and Lisbon curves illustrate a transition, the anti-clockwise movement being very decidedly predominant at Lisbon.

§ 10. Owing to the influence of the season on the type of the S. VI. — 58

inequalities, the mean amplitude obtained by combining hourly values from the whole year is necessarily less than the arithmetic mean of the amplitudes found for any series of equal subdivisions of the year. At some observatories it is customary to measure the difference between the greatest and least of the hourly values, or even between the greatest and least values met with anywhere in the twenty-four hours, tabulating the result under some such heading as *diurnal range*. Diurnal ranges so calculated are, it should be noticed, entirely different—especially in disturbed times—from the amplitudes of ordinary diurnal inequalities. Even in the case of monthly means, variability in the times of occurrence of undisturbed maxima and minima should not be lost sight of.

Again, it should be noticed that as the mean times of occurrence of maxima and minima seldom coincide with exact hours, the amplitudes of inequalities deduced directly from hourly measurements may be sensibly too small. At some stations attempts are made to rectify this, the hourly measurements being either made the basis of continuous curves, or employed in the calculation of Fourier's series with periods of twenty-four hours or their submultiples. The maxima and minima and their exact times of occurrence can then be determined very accurately. This procedure is, however, exceptional, so the amplitudes dealt with in Table VII. are simply the differences between the greatest and least of the mean hourly values. The mean of the twelve monthly amplitudes is taken as unity.

TABLE VII.—Relative Values of Amplitudes of Diurnal Inequalities throughout the Year.

Station.	Epoch.	Element.	Jan.	Feb.	March.	April.	May.	June.	July.	August.	Sept.	Oct.	Nov.	Dec.

" . . .	"	Vert. force	1.05	1.21	1.23	1.19	.77	.80	.83	.70	1.04	1.30	1.03	.85
" . . .	"	Inclination	1.01	1.10	1.18	1.20	.87	.86	.88	.85	1.09	1.19	.96	.81
Mauritius . . .	1878-90	Declination	1.07	1.26	1.30	.97	.85	.60	.70	1.01	1.03	1.14	1.01	1.05
" . . .	1883-90	Hor. force	1.02	.76	1.01	1.11	.97	1.02	.99	1.10	.99	1.02	1.04	.98
" . . .	1884-90	Vert. force	.75	1.04	1.20	1.00	.94	.82	.97	1.36	1.31	1.05	.86	.71

Generally speaking, there is a distinct minimum amplitude in December in the northern and in June in the southern hemisphere. There are usually two approximately equal maxima in summer, with an intermediate badly defined minimum. At Kew the mode of variation of the amplitude throughout the year is fairly similar in all the elements, but this is exceptional. For instance, at Batavia and Mauritius the diurnal variation of the horizontal force is much less variable than that of the declination or vertical force.

§ 11. There seems little doubt that a small lunar diurnal inequality really exists, though some of the data in S, §§ 95-99, seem contradictory. Fiege has analysed the Batavia all-day observations between April 1883 and March 1894, and has found a lunar diurnal inequality in all the elements, showing two maxima and two minima. The mean values found for the amplitudes are: declination, 0'.17; inclination, 0'.06; horizontal force, 17×10^{-6} C.G.S. units; vertical force, 9×10^{-6} C.G.S. According to Fiege, the lunar influence on

disturbances is relatively large. (See Appendix, *Observations . . . at the Mag. and Met. Observatory at Batavia*, vol. xvii. 1894.) Utilizing observations at Bombay and Trevandrum, C. Chambers (*Phil. Trans.* vol. clxxviii. A (1887), p. 1) calculated lunar diurnal inequalities answering to different phases of the moon at different seasons of the year, and concluded "that the bulk of the phenomenon dealt with is, properly speaking, . . . a solar diurnal variation that depends on the relative positions of the sun and moon." The correct way of regarding such data is open to some doubt (see § 14).

§ 12. The secular changes in the magnetic elements seem to proceed at slightly different rates at different seasons of the year (see S, §§ 64-67). The term *annual inequality* is here applied to that part of the annual change in the absolute values that remains unaccounted for by a secular change taking place at a uniform rate throughout the year. Table VIII. gives some recent results. The letters *a* and *q* distinguish results based on all and on quiet days.

December . . .	+5	-4	-2	-2	+3	+1	-2	+1	+1	+7	+5

The data are from the following sources: Kew (*Brit. Assoc. Report*, 1895); St Petersburg (Muller, R, vol. xii. No. 8, 1889; see also Leyst, R, vol. xvii. No. 1, 1894); Tiflis (Rykatchew, R, vol. xiv. No. 1, 1890; see also Mielberg, R, vol. xvii. No. 11, 1894); Batavia (Appendix to *Observations made at the . . . Observatory at Batavia*, vol. xvi. for 1893); Mauritius (*Mauritius Magnetical Reductions*, edited by T. F. Claxton, Mauritius, 1899). The data in Table VIII. have been smoothed, except in the case of Batavia and Mauritius. As Batavia and Mauritius are south of the equator, we see that, when allowance is made for a uniform secular change, the horizontal force is above its mean value in summer at all the stations. Schwalbe has observed this phenomenon in the data for South Georgia. As regards the declination, it is doubtful whether the figures prove more than that the secular change takes place at a nearly uniform rate throughout the year. All-day results for Pavlovsk, Tiflis and Moscow agree fairly in character, but differ somewhat

markedly from the results at Kew. Not unlikely a good deal may depend on the epoch chosen, and according to the Pavlovsk data there is a difference between all and quiet days. (See Walker's *Terrestrial and Cosmical Magnetism*, pp. 72-79; S, §§ 65, 67; and Schwalbe, *Met. Zeit.*, December 1893, p. 449.) Muller gives also annual inequality results in vertical force and inclination at St Petersburg and Pavlovsk, but the vertical force data for different epochs differ widely.

§ 13. Of longer periods the sun-spot, or as it is often termed eleven-years' period, is much the most certain and most important (see S, §§ 46-50). Of late years various researches have thrown further light on the subject. W. Ellis (*Proc. Roy. Soc.* vol. lxiii. 1898, p. 64) has extended his earlier investigations so as

Longer periods.

to include Greenwich data from 1841 to 1896. After allowing for the variations in amplitude depending on the season of the year, he finds for the times of maximum and minimum amplitude of the diurnal inequality at Greenwich, as compared with the times of maximum and minimum sun-spot frequency (according to Wolf), the figures given in Table IX.

TABLE IX.

Phase.	Magnetic Epochs.			Sun-spot Epoch. 1800+
	Declination. 1800+	Horizontal Force. 1800+	Mean. 1800+	
Minimum .	44.3	42.9	43.60	43.5
Maximum .	48.1	49.0	48.55	48.1
Minimum .	57.2	55.1	56.15	56.0
Maximum .	60.6	60.2	60.40	60.1
Minimum .	67.5	67.6	67.55	67.2
Maximum .	70.8	70.9	70.85	70.6
Minimum .	79.0	78.7	78.85	79.0
Maximum .	84.0	83.8	83.90	84.0
Minimum .	89.5	90.0	89.75	90.2
Maximum .	93.5	94.0	93.75	94.0

In S, the conclusion was drawn from earlier work by Stewart, Ellis, and others that the magnetic maxima and minima lagged behind those of the sun-spots; but, as Ellis remarks, this is not confirmed by the more extensive data embodied in Table IX.

§ 14. Bigelow (*U.S. Weather Bureau Bulletin*, No. 11, Part II. 1895, p. 500, &c.) claims to have established the existence of a magnetic period of 26.68 days, and this period was even employed instead of the calendar month in the magnetic tables published by the U.S. Naval Observatory for 1894. Hayward (*T*, vol. iv. 1899, p. 7) has examined magnetic data from several stations, with a view to determining whether they show a 428-days period (Chandler's

period), but with no definite result. Leyst (*R*, vol. xvii. No. 1, 1894), from an analysis of seventeen years' data at St Petersburg and Pavlovsk, has concluded that all the principal planets sensibly influence the earth's magnetism. Except in the case of Mercury, Leyst confined his attention to the declination. According to his figures, all the planets except Mercury (whose influence is in the opposite direction to that of the others) when nearest the earth increase both the absolute value of the westerly declination (at St Petersburg) and also the amplitude of the solar diurnal inequality, the latter effect being the more conspicuous. Some relative numerical results will be found in Leyst's tables xxv. and xlviii. Schuster in several papers has considered the question of periodicities from a critical standpoint (*T*, vol. iii. p. 13; *Nature*, vol. liii. 1896, p. 318, &c.). He shows the difficulty of proving the existence of periodicities of small amplitude, unless observations extend over a very large number of periods. He also shows how spurious periodicities may arise. A spurious period of about 26.1 days, for instance, may very likely present itself when we deal with one or two complete years' observations of an element affected by an ordinary lunar period of 29.53 days. Schuster obtains formulae which he applies to the data advanced by Broun, Hornstein, Liznar and others in favour of a 26 days' period in magnetic phenomena (see S, § 86; also *Wien. Ber.* vol. xci. 1885, p. 474, and vol. xciv. 1887, p. 834). The evidence is, he thinks, in no single case conclusive, but there is a consensus of favourable evidence from so many different sources as to create a presumption that something more than pure chance is concerned. The evidence advanced by Leyst in favour of sensible planetary influence appears to Schuster insufficient.

§ 15. Various tables of data may be found in S, §§ 30-35. One gives the mean declination in 1882 at Kew Observatory as 18° 44'.8 W. In 1900 it was 16° 52'.7 W. Table X. gives mean annual changes during two periods at Kew, Parc St Maur (Paris), and Pavlovsk (St Petersburg), the latter based on papers by Moureaux (*Mém. du Bureau Central Mët.* for 1897, p. B₆₅) and Wild (*Mém. de l'Acad. de St Pétersbourg*, vol. ix. No. 7, 1900).

Secular changes.

TABLE X.—Mean Annual Changes of Magnetic Elements.

	Declination.		Inclination.		(Hor. Force) × 10 ⁵ C.G.S.		(Vert. Force) × 10 ⁵ C.G.S.
	1883-90.	1890-97.	1883-90.	1890-97.	1883-90.	1890-97.	1883-97.
Kew	-7'.1	-6'.3	-1'.1	-2'.0	+21	+24	-1
Parc St Maur	-6'.0	-5'.7	-1'.2	-1'.6	+18	+25	+1
Pavlovsk	-4'.1	-5'.5	0'.0	-0'.6	+6	+14	+16

The - sign represents diminution in westerly declination. In western Europe generally the changes are very similar to those at Kew and Parc St Maur. The *agonic lines* (or loci where the declination is zero) both in Europe and North America are moving westwards; the European line passed through St Petersburg about 1892. For fuller particulars see van Bemmelen (*k. Akad. van Weten. te Amsterdam*, 30th November 1895, and *Supplement to Batavia Observations*, vol. xxi.) and Schott (*T*, vol. ii. p. 123). The rate of movement of the needle to the east appears to be diminishing in western Europe, though greater there than in southern or eastern Europe. In some Asiatic stations (*e.g.*, Irkutsk, Bombay, Hong Kong, Batavia) in 1900 the needle was moving to the west. The inclination has been diminishing for some time in western Europe at an apparently increasing rate; in St Petersburg, however, it increased up to about 1886. The horizontal force is increasing all over Europe, but at most European stations the vertical force appears nearly stationary. A table of annual values of the magnetic elements at most magnetic observatories has appeared in the *Proc. Roy. Soc.* as Appendix Ia to the annual *Reports* of the Kew Observatory Committee since 1895.

§ 16. The secular changes in the declination D and inclination I at a number of American stations have been represented with considerable accuracy by Schott (*U.S. Coast and Geodetic Survey Report* for 1895, App. I. &c.) by formulæ of the type D or I = a₀ + a₁ sin(mt + n); where t is the time since a given epoch, while a₀, a₁, m and n are constants for the particular place. When observations extend over

only a short term of years it is better to use formulæ of the type D or I = a + bt + ct². Littlehales (*T*, vol. i. pp. 62 and 89, vol. ii. p. 68) has calculated secular change formulæ for a variety of stations scattered over the globe. Thus for the Cape of Good Hope he finds:

$$\text{Declination} = 14^\circ.63 + 15''.00 \sin \{0.61(t - 1850) + 77^\circ.8\},$$

$$\text{(North) Inclination} = -49^\circ.11 + 8''.75 \sin \{0.8(t - 1850) + 214^\circ.3\},$$

where t is the date in years.

Bauer has introduced a convenient method of showing secular change graphically. From the centre of a sphere he draws radii

Fig. 5

parallel to the direction of the freely dipping needle and produces them to intersect the tangent plane drawn at the point which answers to the mean position of the needle during the epoch under consideration. The curve formed by these points of intersection

shows the particulars of the secular change. Fig. 5 is the curve for London (slightly modified from *Nature*, vol. lvii. p. 181). As shown by the arrow, it is being described clockwise. In his original work Bauer found no actual exception to this mode of description, though he observed indications suggestive of exceptions on the Pacific coast. Schott and Littlehales have found a considerable number of cases where the direction of description is open to doubt, while in some stations on both the east and west shores of the Pacific it seems clearly anti-clockwise. Fritsche dealing with the secular changes from 1600 to 1885—as given by his *calculated* values of the magnetic elements—at 204 points of intersection of equidistant lines of latitude and longitude, found only sixty-three cases in which the motion was unmistakably clockwise, as against twenty-one cases in which it was clearly the reverse (*Die Elemente des Erdmagnetismus*, pp. 104–8).

§ 17. As already mentioned in § 4, disturbances show periodic variations, but the laws followed depend somewhat on the point of view adopted. We may accept Sabine's or some similar definition of a disturbance, distinguish between positive and negative disturbances, and trace the laws observed by the number or by the mean magnitude of either species; or we may simply take the differences between all- and quiet-day mean values, without going into further details. The conclusions at which Sabine arrived are described in S, §§ 54, &c. The most important of these conclusions, *e.g.*, the existence of times of maximum disturbances at the equinoxes, and the approximate coincidence of years of maximum disturbance with those of sun-spot maxima, are in accord with recent analyses of results from St Petersburg, Parc St Maur, Potsdam, and Greenwich, and made respectively by Muller (R, vol. x. No. 3), Moureaux (T, vol. iv. p. 149), Lüdeling (T, vol. i. p. 147), and Ellis (*Monthly Notices of the Royal Astronomical Society*, December, 1899, p. 142), in whose papers many further interesting details will be found. If the results of investigations such as Sabine's depend slightly on the definition of a disturbance, those of the second point of view described above depend in their turn on the definition of a quiet day, for Sabine's and Wild's quiet days were found by Whipple to show small but decided differences in their mean diurnal inequalities (*Brit. Assoc. Report for 1886*, p. 71). The second point of view is, however, probably the simpler, and it lends itself readily to graphical treatment; thus we can exhibit diurnal inequalities of disturbances in the form of curves of the types 1 or 2. Fig. 6, which is a

Fig. 6.

slight modification of curves given by Ellis (*Brit. Assoc. Report for 1898*, p. 83), shows the algebraical excess of the mean all-day over the mean quiet-day hourly values of the magnetic elements at Greenwich for the epoch 1890–94, thus representing the diurnal inequalities of the disturbances from the second point of view. It will be noticed that the disturbance inequalities in the declination and vertical force are well marked, while that in the horizontal force is insignificant. This latter fact is not inconsistent with the result observed by, for instance, Moureaux at Parc St Maur, that positive and negative horizontal force

disturbances, when treated separately after Sabine's method, show well-marked diurnal inequalities.

§ 18. That large magnetic disturbances occur simultaneously, or nearly so, over large European areas, was known in the time of Gauss, on whose initiative observations were taken at 5-minutes' intervals at a number of stations on certain pre-arranged *term days*. During March 1879 and August 1880 there were some large disturbances, and W. G. Adams took the opportunity of comparing the magnetic curves from a number of observatories fitted with Kew pattern instruments (*B. A. Reports for 1880*, p. 201; and for 1881, p. 463). He found that the more characteristic movements in the case of any element took place, so far as could be judged, simultaneously at all the stations. At comparatively near stations, such as Stonyhurst and Kew, or Coimbra and Lisbon, the curves were in general almost duplicates. At Kew and St Petersburg there was usually considerable difference in detail, and occasionally the movements were in opposite directions. The differences between Toronto, Melbourne, or Zi-ka-wei and the European stations were still more pronounced. In 1896, on the initiative of Eschenhagen, eye observations of declination and horizontal force were made at Washington, Batavia, Manila, Melbourne, and nine European stations, at 5-seconds' intervals during pre-arranged hours. The data from one of these occasions, 28th February, were published by Eschenhagen (*Anhang Ergebnisse der Mag. Beob. in Potsdam*, 1896). The results were similar to those met with by Adams, but the differences in the construction and sensitiveness of the instruments proved a source of trouble. That simultaneity of occurrence is not peculiar to large disturbances was observed by Adams, and any number of examples are afforded by the magnetograms from stations such as Kew and Falmouth, a few hundred miles apart. Probably the most conclusive evidence of practical simultaneity yet afforded is that obtained from observations with bifilar magnetometers of very short period at Potsdam and Wilhelmshaven (see Eschenhagen, T, vol. i. p. 55), taken between 6 and 7 P.M. on six successive days in March 1895. There was no conspicuous disturbance, but a number of small movements, as many as 112 turning-points being observed in the course of an hour. It was found that practically every movement was common to the two stations, and the simultaneity of occurrence was established to within a second or two. A similar inter-comparison of Potsdam, Wilhelmshaven, and Charlottenburg in June 1895 led to similar results.

§ 19. The records from ordinary Kew pattern magnetographs not infrequently show a repetition of regular or nearly regular small rhythmic movements, lasting sometimes for hours (cf. van Bemmelen, *Kon. Akad. van Wetensch., Amsterdam*, 22nd November 1899). The space from crest to crest usually answers to an interval of from 2 to 5 minutes. In 1882 Kohlrausch detected with a very sensitive instrument wave-like variations of magnetic force at intervals of about 12 seconds (*Wied. Ann.* vol. ix. p. 336). Eschenhagen has observed small wave-like variations of horizontal force with a period of about 30 seconds (*Sitz. der k. Preuss. Akad. der Wiss.*, 24th June 1897, &c.). According to Eschenhagen, these *elementary waves* usually occur at night, and their passage may last several hours. In reply to criticisms by Cleveland Abbe, who ascribes the phenomenon to the apparatus, Eschenhagen says that he has obtained practically identical results when employing magnets of different periods of oscillation.

§ 20. Since 1880 there have been detailed investigations into the values of the magnetic elements in several countries. Of these we may mention the surveys of Great Britain and Ireland by Rücker and Thorpe (*Phil. Trans.* vol. clxxxi., A, 1890, p. 53; and vol. clxxxviii., A, 1896), of France and Algeria by Moureaux (*Ann. du Bureau Central Mët.*

Simultaneity of disturbances.

Waves of magnetism.

Magnetic surveys.

de France, vol. i., for years 1884, and 1887 to 1895), of Russia by Smirnow, von Tillo, and others (R, vol. viii. No. 2, 1881; and vol. ix., Nos. 4 and 5, 1885), of Japan by Knott and Tanakadate (*Journal Coll. of Science Imp. University, Japan*, vol. ii. p. 163), of Italy by Chistoni and Palazzo (*Ann. dell' Uff. Centrale Met. e Geod.* vol. xiv. part 1, 1892, p. 57), of Switzerland by Batelli (*Ann. dell' Uff. Centr. Met.* vol. xiv. part 1, p. 83), of the Netherlands by van Rÿckeversel (*A Magnetic Survey of the Netherlands for the Epoch 1st January 1891*, Rotterdam, 1895), of South Sweden by Gyllensköld (*lg. Svenska Vet-Akad. Handlingar*, vol. xxvii. No. 7, 1895; and T, vol. i. p. 200), of Austria by Liznar (*Denkschriften der Math.-Naturwiss. Classe der k. Akad. der Wiss. Wien*, vol. lxiii, 1895; and vol. lxvii. 1899), and of Maryland, U.S., by Bauer (*Maryland Geological Survey Special Publication*, vol. i. part 5). The successful accomplishment of a magnetic survey requires that observations in the field be supplemented by records from fixed observatories, the latter being employed to determine the corrections necessary to reduce the field observations to a common epoch. Irregular magnetic changes are usually simultaneous and of similar amplitude over considerable areas, while secular changes and diurnal inequalities (allowing for differences of local time) are also very similar. Thus a comparatively small number of well-distributed magnetic observatories should suffice to supply the data of this character required for a survey. Unfortunately, however, the distribution of magnetic observatories is seldom ideal (see von Bezold and Rykatcheff, *Brit. Assoc. Report*, 1898, p. 743; and Schmidt, T, vol. ii., p. 27). Thus in the United Kingdom, Greenwich, Kew, and Falmouth differ little in latitude, whilst during Rücker and Thorpe's surveys there was no magnetograph in Scotland or Ireland. Apart from observatories, secular changes can be found only by repeating observations at a series of stations after a considerable interval of time. As the instruments employed in a survey are exposed to the vicissitudes of travel, it is desirable to compare them occasionally with standard instruments at a fixed observatory; such comparisons also provide the means of eliminating the peculiarities of different instruments. (For results of recent inter-comparisons by van Rÿckeversel, Moureaux, and others, see T, vol. ii. p. 133; vol. iii.; pp. 186, 187; and *Brit. Assoc. Report*, 1896, p. 87.)

§ 21. The survey most likely to interest readers of this article is that of Rücker and Thorpe. After reducing their data to a common epoch, they proceeded as follows:—Dividing the United Kingdom into districts, from all the observations in a particular district they calculated a mean value for each element, answering to an imaginary central station, and also mean values for the changes in each element per degree of latitude or longitude throughout the district. From these data they calculated values of the elements for points defined by whole degrees of longitude and half degrees of latitude. Thence they found where isogonals, isoclinals, &c, cut the lines of latitude. The curves obtained by joining these successive points of intersection on a map are called *district lines* or *curves*. Rücker and Thorpe's next step was to obtain formulæ giving smooth curves of continuous curvature, approximating as closely as possible to the district lines. These smooth curves are called *terrestrial isomagnetics*; they may be supposed to show what the magnetic elements would be in the absence of disturbances peculiar to special parts of the survey area or its immediately coterminous regions. The component magnetic forces answering to the isomagnetics may be regarded as representing the *normal field*, and when we subtract them from the components actually observed, we obtain forces answering

to a residual field, which may be ascribed to regional disturbances. When the vertical disturbing force is downwards, *i.e.*, the observed vertical component larger than that answering to the isomagnetics, Rücker and Thorpe regard it as positive, and the lines which are the loci where the largest positive values occur are termed by them *ridge lines*. Almost without exception, the resultant of the horizontal components of the disturbing forces pointed towards these ridge lines throughout a considerable area on both sides. The phenomena are similar to what would occur if ridge lines indicated the position of the summits of underground masses of magnetic material, magnetized so as to attract the N.-seeking pole of a magnet. Rücker and Thorpe are inclined to believe in the real existence of these subterranean mountains, even when there is no directly confirmatory geological evidence. They point out that if subterranean magnetic rocks are the cause of the phenomena, they must be of considerable extent, for theory and experiment alike indicate that thin basaltic sheets or dykes, or limited masses of trap rock, produce no measurable effect except in their immediate vicinity. In support of their conclusion, Rücker and Thorpe dwell on the fact that in the United Kingdom large masses of basalt, such as occur in Skye, Mull, Antrim, North Wales, or the Scottish coal-field, are invariably centres of attraction for the N.-seeking pole of a magnet, while they did not find a single clear case where a large mass of igneous rock acted as a centre of repulsion. One of the smaller anomalies observed by Rücker and Thorpe in the Thames valley, near London, is supposed by Moureaux (*Ann. du Bureau Central Météorologique de France*, 1890, tome i. p. B₉₅) to be probably associated with interesting anomalies which he has detected in the Paris basin.

§ 22. In some instances regional magnetic disturbances are associated with geodetic anomalies. This is the case in an elongated area including Moscow, surveyed magnetically by Fritsche (*Bull. Soc. Imp. des Naturalistes de Moscou*, No. 4, 1893, p. 381; also T, vol. i. p. 50). Again, Eschenhagen has detected magnetic anomalies in an area including the Harz mountains, where deflections of the plumb line from the normal had been observed (*Forsch. zur deutschen Landes. . . Elfter Bd., Heft 1*, 1898; also T, vol. iii. p. 77). Eschenhagen found a magnetic *ridge line* running approximately parallel to the line of no deflection of the plumb line. In these cases the disturbed areas are considerable, but the disturbances are comparatively small. On the other hand, enormous disturbances have been observed over certain limited areas. One of the most remarkable of these is an area, about 3 miles long by 1¼ miles at its widest, near Port Walcott, off the north-west Australian coast. The results of a survey made here by H.M.S. *Penguin* have been discussed by Captain Creak (*Phil. Trans.* vol. clxxxvii. A, 1896, p. 345). Within the narrow area specified the declination varied from 26° W. to 56° E., and the inclination from 50° to nearly 80°, the observations being taken some 80 feet above sea bottom. Similar extraordinary anomalies in the province of Kursk, Russia, have been examined and discussed by Moureaux (*Ann. du Bureau Central Mét. de France* for 1897, p. B₂₆).

§ 23. If we assume that the magnetic forces on the earth's surface are derivable from a potential V, we can express V in terms of two series of solid spherical harmonics, one containing *Gaussian constants*, the other positive, integral powers of r, the radius vector from the earth's centre. Let λ denote east longitude from Greenwich, and let μ = cos (π/2 - l), where l is latitude. Also let

$$H_n^m = (1 - \mu^2)^{\frac{m}{2}} \left[\mu^{n-m} - \frac{(n-m)(n-m-1)}{2(2n-1)} \mu^{n-m-2} - \dots \right],$$

where n and m denote any positive integers, m being not greater than n . Then denoting by R the earth's mean radius, we have

$$V/R = \Sigma(R/r)^{n+1} [H_n^m (g_n^m \cos m\lambda + h_n^m \sin m\lambda)] + \Sigma(r/R)^n [H_n^m (g_{-n}^m \cos m\lambda + h_{-n}^m \sin m\lambda)];$$

where Σ denotes summation of m from 0 to n inclusive, and then summation of n from 0 to ∞ . In this equation $g_n^m, h_n^m, g_{-n}^m, h_{-n}^m$ are constants, the former pair representing what are generally termed *Gaussian constants*.

The series with negative powers of r answers to forces whose origin is within the earth's surface, that with positive powers to forces with an external origin. Gauss found that forces of this latter class if existent were very small, and usually they have been left out of account.

There are three Gaussian constants of the first order g_1^0, g_1^1, h_1^1 , five of the second order, seven of the third, and so on. The coefficient of a Gaussian constant of the n th order is a spherical harmonic of the n th degree. It is perhaps most usual to take R as the unit length, in which case the first order terms may be written

$$V_1 = r^{-2} \{ g_1^0 \sin \lambda + (g_1^1 \cos \lambda + h_1^1 \sin \lambda) \cos \lambda \}.$$

In reality the earth is not a perfect sphere, and in the elaborate work on this subject by J. C. Adams it is treated as a spheroid. It is usual, however, to treat the earth as a sphere, and for simplicity we shall here treat it as such. We then have for components of force

$$X = -r^{-1} (1 - \mu^2)^{1/2} (dV/d\mu) \text{ towards the north,} \\ Y = -r^{-1} (1 - \mu^2)^{-1/2} dV/d\lambda \quad \text{,, west,} \\ Z = -dV/dr \text{ vertically downwards.}$$

Over the surface $r=R$, and the expressions for the components of force are functions only of λ and μ . Supposing all the Gaussian constants for any given epoch known, the above expressions would supply the values of $X, Y,$ and Z all over the earth's surface. To determine the Gaussian constants for any given epoch we proceed in the reverse direction, *i.e.*, we equate observed values of $X, Y,$ and Z to the theoretical values involving g_n^m , &c.

If we knew the value of the component forces at regularly distributed stations all over the earth's surface, we could determine each Gaussian constant independently of the others. Different ways of doing this have been indicated by J. C. Adams and Schuster. Our knowledge, however, of either Arctic or Antarctic regions is scanty, and in practice recourse must be had to methods in which the constants are not determined independently. The consequence, unfortunately, is that the values found for some of the less important constants, even of the lower orders, may depend very sensibly on how large a portion of the polar regions is excluded from the calculation, and on the number of constants of the higher orders which are retained. This is shown very clearly by W. G. Adams (*Brit. Assoc. Report* for 1898, p. 109) in discussing the results found by J. C. Adams for the two epochs 1845 and 1880, notably in the case of the constant g_2^0 .

W. G. Adams devotes several tables to the values of the Gaussian constants as found by Erman-Petersen for 1829, by Gauss for 1830, by J. C. Adams for 1845 and 1880, and by Neumayer, Schmidt, and Fritsche for 1885. The most recent of these data for the constants of the first order are as follows:—

TABLE XI.—Gaussian Constants of the First Order.

Constant	Adams. 1880.	Neumayer. 1885.	Schmidt. 1885.	Fritsche. 1885.
g_1^0	+·316843	+·315720	+·317346	+·31635
g_1^1	+·024273	+·024814	+·023556	+·02414
h_1^1	-·060300	-·060258	-·059842	-·05914

The agreement is closer than might have been expected, considering that the number of constants retained was different in each case, Neumayer, for instance, neglecting all but the first twenty-four, as against fifty retained by Adams. Even in the case of the higher constants there are few instances of differences in sign. Still the last two of these figures at least had better be regarded as ornamental. It should be noticed that writers differ in the sign they give to V , and that, owing to a difference in his definition of a surface harmonic, Schmidt's values for the Gaussian constants, as given elsewhere by himself, require multiplication by factors as explained by W. G. Adams (*loc. cit.* pp. 134-136).

§ 24. The neglect of the second series in our original expression for V is, as already stated, one source of uncertainty, and a second is the possibility that some part of the magnetic forces may not arise

from a potential. J. C. Adams made some calculations according to which g_{-1}^0/g_1^0 is very small, but g_{-5}^0 came out somewhat large. Schmidt's calculations led him to conclude that about one-fortieth of the force on the average arose from a potential answering to external forces, and that an even larger part had no potential. This would imply that the line integral of the magnetic force round closed areas on the earth's surface does not in general vanish. The physical concomitant would be vertical earth-air electric currents. Schmidt's final estimate of the average intensity of these currents at the epoch 1885 appears to be 0·17 ampere per square kilometre (*Abhand. der bayer. Akad. der Wiss.* Bd. xix. 1895). An earlier paper put it at 0·1 (*Brit. Assoc. Report* for 1894, p. 570). Bauer (T, vol. ii. p. 11), employing the same experimental data as Schmidt, reached a similar conclusion from the differences between integrals, taken round parallels of latitude at intervals of 5° from 60° N. to 60° S. Bauer found a very asymmetrical distribution, the current being downwards between 5° and 45° N. and between 15° and 40° S., while elsewhere it was upwards. Von Bezold also took line integrals round parallels of latitude, and comparing their values with the potential ranges as given by Schmidt's figures, obtained evidence favourable to the existence of vertical currents (*Sitz. k. Akad. der Wiss.*, Berlin, 1897, No. xviii.; also T, vol. iii. p. 191). Fritsche has treated the problem similarly, but has considered a larger number of parallels, and at two separate epochs, *viz.*, 1842 and 1885 (*Die Elemente des Erdmagnetismus*, p. 103). The values of the integrals round the same parallel at the two epochs seldom agreed closely, and sometimes differed in sign. As a large alteration in the phenomena in the course of forty-three years seems improbable, the most natural conclusion is that the values of line integrals round parallels of latitude are too uncertain to afford a satisfactory criterion as to the real existence of earth-air currents. Similar negative results seem to flow from the calculation of line integrals round the best surveyed areas in Europe (see von Bezold, *l.c.*; Ricker, T, vol. i. p. 77, and *Nature*, vol. lvii. pp. 160 and 180; Liznar, *Met. Zeit.* for 1898, p. 175; and von Gyllensköld, *k. Svenska Vet. Akad. Handlingar*, vol. xxvii. No. 7, 1895). There are somewhat serious physical difficulties in the way of currents of the size calculated by Schmidt (see ATMOSPHERIC ELECTRICITY, *Ency. Brit.* vol. xxv. § 13).

§ 25. The forces arising from terms in the Gaussian potential which depend on constants of the n th order vary as r^{-n-2} , where r is the distance from the earth's centre. If F represent the value at sea-level of any component of force answering to Gaussian constants of the n th order, the value $F + \delta F$ at height h is given by $(F + \delta F)/F = \{R/(R+h)\}^{n+2}$, where R is the earth's radius. Thus so long as h/R is small we have very approximately $\delta F/F = -(n+2)h/R$. As we have seen, the terms depending on Gaussian constants of the first order (*i.e.*, $n=1$) are much the most important; thus on the Gaussian theory we should have approximately

$$\delta X/X = \delta Y/Y = \delta Z/Z = -3h/R.$$

Thus all the components should decrease as we go upwards at the same rate, the declination and inclination remaining unaffected. Liznar has compared this equation with the results of his Austrian survey (*Sitz. der k. Kais. Akad. der Wiss. Wien., Math.-Nat. Classe*, Bd. cvii. Abth. ii., 1898). Subdividing his stations into three groups according to altitude, he concluded that the westerly component and the declination increased with the altitude, and that while the northerly and vertical components decreased, they did so at thrice the rate indicated by theory. These conspicuous departures from theory have been ascribed to electrical currents in the atmosphere, some of which would have to be horizontal. Geitel has pointed out serious difficulties in the way of this explanation (T, vol. iv. p. 63). Van Rÿckevoersel and van Bemmel found the horizontal force on the Rigi to decrease slightly with the altitude, while the vertical force increased in somewhat larger measure; but the differences were so small that they were indisposed to regard their conclusions as final (T, vol. ii., 1897, p. 76). It should be noticed that Liznar's theoretical formula, like the Gaussian analysis—so long as only lower order terms are retained—applies only to the earth's field as freed from all local or even regional disturbances; and that presumably a good deal of the material above sea-level in Austria is by no means non-magnetic. According to Liznar's views, diurnal variation phenomena should vary sensibly with the height: if this be the case, his advocacy of the institution of some high-level magnetic observatories is worthy of support.

§ 26. Schuster has attempted to obtain a potential analogous to the Gaussian potential from which the regular diurnal changes of the magnetic elements all over the earth may be found by differentiation (*Phil. Trans.*, A, vol. clxxx. 1889, p. 467). From the mean summer and winter diurnal variations of the northerly and easterly components of force during 1870 at Greenwich, Lisbon, St Petersburg, and Bombay, he calculated the values of eight constants analogous to Gaussian constants, and from considerations as to the times of occurrence of the diurnal maxima and minima of vertical

force he concluded that his potential must, unlike the Gaussian, proceed in positive powers of r . This would ascribe the diurnal variations to a source external to the earth. Schuster found, however, that the amplitude of the diurnal vertical force inequality calculated from his potential did not accord with observation. His final conclusion was that the principal cause of the diurnal variations is probably electric currents in the atmosphere, but that there are also induced currents inside the earth which increase the horizontal components and diminish the vertical component. Von Bezold has based on Schuster's results a series of vector diagrams showing the mean diurnal variation for the summer of 1870, in a variety of latitudes (*Sitz. der k. Preuss. Akad.*, 1897, No. xviii. See also *Met. Zeit.*, February 1898). A repetition of Schuster's calculations for a more recent epoch, making use of the best available data, and a critical comparison with the phenomena at a variety of stations, seems desirable.

§ 27. Employing V as before for the Gaussian potential, von Bezold puts $V = V_n + V_a$, where V_n is the mean value of V for the parallel of latitude, while V_a is the anomaly (*Sitz. der k. Preuss. Akad.*, No. xviii., 1895, p. 363). He found that approximately $V_n = V_v$ where $V_v = K \times \sin$ latitude, with K a constant. Von Bezold calls V_n the empirical normal, and V_v the theoretical normal potential. He regards V_a as answering to disturbances, and constructs is-anomaly curves (along which V_a is constant), from which he draws conclusions as to the character of the disturbing forces. The fact that V_n and V_v are nearly equal simply means, as pointed out by Schmidt, that g_1^0 is much the largest Gaussian constant of the type g_n^0 . Von Bezold mentions this in a second paper, where he compares observed magnetic forces with those calculated from V_v , accepting the Neumayer-Petersen value $\cdot 31572$ for g_1^0 (*Sitz. der k. Preuss. Akad.*, No. 50, 1895, p. 1119). Bauer seems originally to have taken the same definition of normal field as von Bezold, recognizing, however, what seems to have escaped von Bezold, that V_v simply answers to a uniform magnetization parallel to the earth's axis (*Amer. Jour. of Sc.* vol. 1. pp. 109, 189, 314). In a second paper Bauer takes for the earth's normal field that depending on the Gaussian constants of the first order (*T*, vol. i. p. 169). This field also answers to a uniform magnetization, but it is parallel to a diameter whose direction cosines relative to the earth's rotation axis and to two perpendicular axes, one in, the other perpendicular to the Greenwich meridian, are proportional to $g_1^0, g_1^1,$ and h_1^1 . Accepting the Neumayer-Petersen figures, Bauer calculates the component forces answering to his normal distribution, and attributes the difference between them and the observed values, as tabulated by Schmidt, to a residual or disturbing magnetization whose nature he illustrates diagrammatically. In a third paper he follows a similar course, but takes Schmidt's values for g_1^0, g_1^1, h_1^1 , and compares the corresponding theoretical values of the component forces with the observed values at 1800 points, instead of at 84 as previously (*T*, vol. iv., 1899, p. 33). Bauer concludes that if his residual field arises from electric currents, these must be inside the earth. He is inclined apparently to associate the residual field intimately with the irregularities in temperature distribution on the earth's surface, owing to a resemblance between his curves and the lines of isabnormal temperature in Hann's *Atlas der Meteorologie*.

Rücker (*T*, vol. iv. p. 113) falls in with the view that the "magnetic field of the earth may be regarded as that primarily due to a uniformly magnetized globe disturbed by some secondary causes." In reference, however, to Bauer's suggestion, he points out that Hann's isabnormals of temperature relate to a purely surface phenomenon, whereas over the greater part of the earth it is the temperature at the bottom of the ocean that would naturally influence magnetic phenomena. Though differing so far from Bauer, Rücker is himself disposed to regard temperature as a not improbable cause of the secondary field. He had been struck by the fact that Wilde had succeeded in reproducing some of the most conspicuous features of the earth's magnetization by a contrivance called a *magnetarium*, consisting essentially of a globe representing the earth's surface inside which is a concentric globe, round which wire is coiled in planes inclined at $23\frac{1}{2}^\circ$ to the equator. Between the two globes is a spherical shell of wire gauze, round which another wire is coiled in planes perpendicular to the geographical axis. Currents are sent through the two circuits. By making the axis of the inner globe describe a cone of constant angle about that of the outer, Wilde claims to imitate the secular change met with on the earth. If the two currents in the magnetarium be regarded as answering to the normal field, the chief substitute for the secondary field would seem to be a coating of thin sheet iron put by Wilde over those parts of the interior surface of the outer globe which correspond to oceans. Pursuing this idea, Rücker points out that in tropical oceans the low temperature at the bottom must increase

the local thickness of the stratum whose temperature is low enough to permit of magnetic material remaining magnetic. Rücker's calculations, however, as applied to Bauer's figures for the secondary field, seem to show that this explanation will not suffice unless the permeability of sub-oceanic strata largely exceeds that of ordinary basaltic rocks or even magnetite.

§ 28. The magnetic poles where the horizontal component vanishes do not, it is believed, lie on one diameter, and the same is true of the two points where the total force is a maximum; thus the term *magnetic axis* could not correctly be applied to a diameter passing through any one of these points. The term has, however, been applied to that diameter which is parallel to the field which depends on the Gaussian constants of the first order (*i.e.*, Bauer's normal field). The position of this diameter varies with the values of the Gaussian constants as shown in Table XII.

TABLE XII.—Co-ordinates of North End of Magnetic Axis.

Epoch.	Authority.	North Latitude.	Longitude West of Greenwich.
1650	Fritsche	82° 50'	42° 55'
1836	"	78 27	63 35
1845	Adams (for Gaussian constants) .	78 44	64 20
1880	"	78 24	68 4
1885	Neumayer-Petersen and Bauer	78 3	67 3
1885	Neumayer-Schmidt	78 34	68 31

According to the table, the magnetic axis has been moving from east to west, inclined at a nearly constant angle to the earth's geographical axis. Other axes possessing more complicated properties in relation to the earth's magnetism, for which distinctive terms seem desirable, have had their positions determined by Schmidt (*T*, vol. i., 1896, p. 18).

§ 29. If a sphere be uniformly magnetized, the potential at a distance r from its centre, in a direction inclined at an angle δ to the magnetic axis, is $M \cos \delta r^{-2}$, where M is the magnetic moment. Comparing this with the expression in § 23 for the earth's potential V , we see that the earth's magnetic moment answering to the Gaussian constants of the first order is given by $M = R^3 \{ (g_1^0)^2 + (g_1^1)^2 + (h_1^1)^2 \}^{\frac{1}{2}}$, where R is the earth's radius. M is known as the *earth's magnetic moment*. The following are some of the numerical results found for M/R^3 :—

TABLE XIII.—Value of M/R^3 in C.G.S. Units.

Epoch.	Authority.	Moment ÷ (Earth's Radius) ³ .
1650	Fritsche	·3260
1830	Gauss (for constants)	·3309
1836	Fritsche	·3262
1845	Adams (for constants)	·3282
1880	"	·3234
1885	Neumayer-Petersen and Bauer	·3224
1885	Schmidt	·3230

The table suggests a slight diminution in the moment since 1845, but the degree of accuracy attributable to the figures, especially the earlier ones, is extremely doubtful.

§ 30. Folgeraiter has found that old vases from Etruscan and other sources are magnetic, and from combined observation and experiment he believes that the magnetization they possess was acquired during the cooling which followed their baking, and has remained unaltered since that epoch (*R. Acad. Lincei Atti* viii. 1899, pp. 69, 121, 176, 269; also previous volumes; see also *Séances de la Soc. Franç. de Physique*, 1899, p. 113). Experiment has supplied him with formulæ connecting the magnetization shown by clay vases with their orientation when cooling in known magnetic fields, and the application of these formulæ to the magnetic phenomena presented by old vases leads him to assign definite values to the magnetic inclination at the time and place of their manufacture. According to Folgeraiter, the inclination in central Italy was southerly for at least two centuries prior to 600 B.C., when it changed sign. In 400 B.C. it was about 20° N. Since 100 B.C. the change has been relatively small. If Folgeraiter's conclusions should be confirmed from other sources, we may expect similar reasoning to apply to rocks of volcanic origin which have cooled rapidly. This would certainly open a wide field for inquiry.

(C. CH.)

Magneto-Optics.—The first relation between magnetism and light was discovered by Faraday,¹ who proved that the plane of polarization of a ray of light was rotated when the ray travelled, through certain substances, parallel to the lines of magnetic force. This power of rotating the plane of polarization in a magnetic field has been shown to be possessed by all refracting substances, whether they are in the solid, liquid, or gaseous state. The rotation by gases was established independently by H. Becquerel,² and Kundt and Röntgen,³ while Kundt⁴ found that films of the magnetic metals, iron, cobalt, nickel, thin enough to be transparent, produced enormous rotations, these being in iron and cobalt magnetized to saturation at the rate of 200,000° per cm. of thickness, and in nickel about 89,000°. The direction of rotation is not the same in all bodies. If we call the rotation positive when it is related to the direction of the magnetic force, like rotation and translation in a right-handed screw, or, what is equivalent, when it is in the direction of the electric currents which would produce a magnetic field in the same direction as that which produces the rotation, then most substances produce positive rotation. Among those that produce negative rotation are ferrous and ferric salts, ferri-cyanide of potassium, the salts of lanthanum, cerium and didymium, and chloride of titanium.⁵

For slightly magnetizable substances the amount of rotation in a space PQ is proportional to the difference between the magnetic potential at P and Q; or if θ is the rotation in PQ, Ω_P , Ω_Q , the magnetic potential at P and Q, then

$$\theta = R(\Omega_P - \Omega_Q),$$

where R is a constant, called Verdet's constant, which depends upon the refracting substance, the wave-length of the light, and the temperature. The following are the values of R (when the rotation is expressed in circular measure) for the D line and a temperature of 18° C. :—

Substance.	R × 10 ⁵ .	Observer.
Carbon-bisulphide .	{ 1·222	Lord Rayleigh ⁶ and Köpse ⁷
	{ 1·225	
Water	{ ·377	Arons. ⁹
	{ ·3808	
Alcohol	·330	Rodger and Watson. ⁸
Ether	·315	Du Bois. ¹⁰
Oxygen (at 1 atmosphere)	·000179	Kundt and Röntgen (<i>l.c.</i>).
Faraday's heavy glass .	1·738	

The variation of Verdet's constant with temperature has been determined for carbon-bisulphide and water by Rodger and Watson (*l.c.*). They find if R_t , R_0 are the values of Verdet's constant at $t^\circ\text{C}$. and 0°C . respectively, then for CS_2 , $R_t = R_0(1 - \cdot0016961t)$, and for H_2O , $R_t = R_0(1 - \cdot0000305t - \cdot00000305t^2)$.

For the magnetic metals Kundt found that the rotation did not increase so rapidly as the magnetic force, but that as this force was increased the rotation reached a maximum value. This suggests that the rotation is proportional to the intensity of magnetization, and not to the magnetic force.

The amount of rotation in a given field depends greatly upon the wave-length of the light; the shorter the wave-length the greater the rotation, the rotation varying a little more rapidly than the inverse square of the wave-length. Verdet¹¹ has compared in the cases of carbon bisulphide and creosote the rotation given by the formula

$$\theta = mc\gamma \frac{c^2}{\lambda^2} \left(c - \lambda \frac{di}{d\lambda} \right)$$

with those actually observed; in this formula θ is the angular rotation of the plane of polarization, m a constant depending on the medium, λ the wave-length of the light in air, and i its index of refraction in the medium. Verdet found that though the agreement is fair, the differences are greater than can be explained by errors of experiment.

Verdet¹² has shown that the rotation of a salt solution is the sum of the rotations due to the salt and the solvent; thus, by mixing a salt which produces negative rotation with water which produces positive rotation, it is possible to get a solution which does not exhibit any rotation. Such solutions are not in general magnetically neutral. By mixing diamagnetic and paramagnetic substances we can get magnetically neutral solutions, which, however, produce a finite rotation of the plane of polarization. The relation of the magnetic rotation to chemical constitution has been studied in great detail by Perkin,¹³ Wachsmuth,¹⁴ Jahn,¹⁵ and Schönrock.¹⁶

The rotation of the plane of polarization may conveniently be regarded as denoting that the velocity of propagation of circular-polarized light travelling along the lines of magnetic force depends upon the direction of rotation of the ray, the velocity when the rotation is related to the direction of the magnetic force, like rotation and translation on a right-handed screw being different from that for a left-handed rotation. A plane-polarized ray may be regarded as compounded of two oppositely circularly-polarized rays, and as these travel along the lines of magnetic force with different velocities, the one will gain or lose in phase on the other, so that when they are again compounded they will correspond to a plane-polarized ray, but in consequence of the change of phase the plane of polarization will not coincide with its original position.

Reflection from a Magnet.—Kerr¹⁷ in 1877 found that when plane-polarized light is incident on the pole of an electromagnet, polished so as to act like a mirror, the plane of polarization of the reflected light is rotated by the magnet. Further experiments on this phenomenon have been made by Righi,¹⁸ Kundt,¹⁹ Du Bois,²⁰ Sissingh,²¹ Hall,²² Hurion,²³ Kaz,²⁴ and Zeeman.²⁵ The simplest case is when the incident plane-polarized light falls normally on the pole of an electromagnet. When the magnet is not excited the reflected ray is plane-polarized; when the magnet is excited the plane of polarization is rotated through a small angle, the direction of rotation being opposite to that of the currents exciting the pole. Righi found that the reflected light was slightly elliptically polarized, the axes of the ellipse being of very unequal magnitude. A piece of gold-leaf placed over the pole entirely stops the rotation, showing that it is not produced in the air near the pole. Rotation takes place from magnetized nickel and cobalt as well as from iron, and is in the same direction (Hall). Righi has shown that the rotation at reflection is greater for long waves than for short, whereas, as we have seen, the Faraday rotation is greater for short waves than for long. The rotation for different coloured light from iron, nickel, cobalt, and magnetite has been measured by Du Bois; in magnetite the direction of rotation is opposite to that of the other metals. When the light is incident obliquely and not normally on the polished pole of an electromagnet, it is elliptically polarized after reflection, even when the plane of polarization is parallel or at right angles to the plane of incidence. According to Righi, the amount of rotation when the plane of polarization of the incident light is perpendicular to the plane of incidence reaches a maximum when the angle of incidence is between 44° and 68°, while when the light is polarized in the plane of incidence the rotation steadily decreases as the angle of incidence is increased. The rotation when the light is polarized in the plane of incidence is always less than

when it is polarized at right angles to that plane, except when the incidence is normal, when the two rotations are of course equal.

Reflection from Tangentially Magnetized Iron.—In this case Kerr²⁶ found:—(1) When the plane of incidence is perpendicular to the lines of magnetic force, no rotation of the reflected light is produced by magnetization; (2) no rotation is produced when the light is incident normally; (3) when the incidence is oblique, the lines of magnetic force being in the plane of incidence, the reflected light is elliptically polarized after reflection, and the axes of the ellipse are not in and at right angles to the plane of incidence. When the light is polarized in the plane of incidence, the rotation is at all angles of incidence in the opposite direction to that of the currents which would produce a magnetic field of the same sign as the magnet. When the light is polarized at right angles to the plane of incidence, the rotation is in the same direction as these currents when the angle of incidence is between 0° and 75° according to Kerr, between 0° and 80° according to Kundt, and between 0° and 78° 54' according to Righi. When the incidence is more oblique than this, the rotation of the plane of polarization is in the opposite direction to the electric currents which would produce a magnetic field of the same sign.

The theory of the phenomena just described has been dealt with by Airy,²⁷ C. Neumann,²⁸ Maxwell,²⁹ Fitzgerald,³⁰ Rowland,³¹ H. A. Lorentz,³² Voight,³³ Ketteler,³⁴ van Loghem,³⁵ Potier,³⁶ Basset,³⁷ Goldhammer,³⁸ Drude,³⁹ J. J. Thomson,⁴⁰ and Leatham;⁴¹ for a critical discussion of many of these theories we refer the reader to Larmor's⁴² British Association Report. Most of these theories have proceeded on the plan of adding to the expression for the electromotive force terms indicating a force similar in character to that discovered by Hall (see MAGNETISM) in metallic conductors carrying a current in a magnetic field, i.e., an electromotive force at right angles to the plane containing the magnetic force and the electric current, and proportional to the sine of the angle between these vectors. The introduction of a term of this kind gives rotation of the plane of polarization by transmission through all refracting substance, and by reflection from magnetized metals, and shows a fair agreement between the theoretical and experimental results. The simplest way of treating the questions seems, however, to be to go to the equations which represent the propagation of a wave travelling through a medium containing ions. A moving ion in a magnetic field will be acted upon by a mechanical force which is at right angles to its direction of motion, and also to the magnetic force, and is equal per unit charge to the product of these two vectors and the sine of the angle between them. For the sake of brevity we will take the special case of a wave travelling parallel to the magnetic force in the direction of the axis of z.

Then supposing that all the ions are of the same kind, and that there are *n* of these each with mass *m* and charge *e* per unit volume, the equations representing the field are (see art. ELECTRICITY, *Electric Waves*, vol. xxviii. p. 71):—

$$\begin{aligned} K_0 \frac{dX_0}{dt} + 4\pi ne \frac{d\xi}{dt} &= \frac{d\beta}{dz}; \\ \frac{dX_0}{dz} &= \frac{d\beta}{dt}; \\ K_0 \frac{dY_0}{dt} + 4\pi ne \frac{d\eta}{dt} &= -\frac{d\alpha}{dz}; \\ \frac{dY_0}{dz} &= -\frac{d\alpha}{dt}; \\ m \frac{d^2\xi}{dt^2} + R_1 \frac{d\xi}{dt} + a\xi &= \left(X_0 + \frac{4\pi}{3} ne\xi \right) e + H e \frac{d\eta}{dt} \\ m \frac{d^2\eta}{dt^2} + R_1 \frac{d\eta}{dt} + a\eta &= \left(Y_0 + \frac{4\pi}{3} ne\eta \right) e - H e \frac{d\xi}{dt}; \end{aligned}$$

where *H* is the external magnetic field, *X*₀, *Y*₀ the components of the part of the electric force in the wave not due to the charges on the atoms, *a* and *β* the components of the magnetic force, *ξ* and *η* the co-ordinates of an ion, *R*₁ the coefficient of resistance to the motion of the ions, and *a* the force at unit distance tending to bring the ion back to its position of equilibrium, *K*₀ the specific inductive capacity of a vacuum. If the variables are proportional to $e^{i(p t - q z)}$ we find by substitution that *m* is given by the equation

$$q^2 - K_0 p^2 - \frac{4\pi ne^2 p^2 P}{P^2 - H^2 e^2 p^2} = \pm \frac{4\pi ne^3 H p^3}{P^2 - H^2 e^2 p^2}$$

where

$$P = \left(a - \frac{4\pi}{3} ne^2 \right) + R_1 i p - m p^2.$$

If *q*₁, *q*₂ are the roots of this equation, then corresponding to *q*₁ we have *X*₀ = *iY*₀ and to *q*₂ *X*₀ = -*iY*₀. We thus get two oppositely circular-polarized rays travelling with the velocities *p/q*₁ and *p/q*₂ respectively. The rotation of the plane of polarization per unit length is *m*₁ - *m*₂; and this can, if we neglect terms in *H*², be shown to be equal to

$$\frac{(\mu^2 - 1)p^2 H}{\mu 4\pi ne V_0^3},$$

where *μ* is the refractive index for light of period, *p*, and *V*₀ is the velocity of light through a vacuum. We see from the equations that the rotation is very large for such a value of *p* as makes *P* = 0: this value corresponds to a free period of the ions, so that the rotation ought to be very large in the neighbourhood of an absorption band. This has been verified for sodium vapour by Macaluso and Corbino.⁴³

If plane-polarized light falls normally on a plane face of the medium containing the ions, then if the electric force in the incident wave is parallel to *x* and is equal to the real part of $A e^{i(p t - q z)}$, if the reflected beam in which the electric force is parallel to *x* is represented by $B e^{i(p t + q z)}$ and the reflected beam in which the electric force is parallel to the axis of *y* by $C e^{i(p t + q z)}$, then the conditions that the magnetic force parallel to the surface is continuous, and that the electric forces parallel to the surface in the air are continuous with *Y*₀, *X*₀ in the medium, give

$$\frac{A}{(q + q_1)(q + q_2)} = \frac{B}{(q^2 - q_1 q_2)} = \frac{iC}{q(q_2 - q_1)}$$

or approximately, since *m*₁ and *m*₂ are nearly equal,

$$\frac{iC}{B} = \frac{m(m_2 - m_1)}{m^2 - m_1^2} = \frac{(\mu^2 - 1)pH}{4\pi\mu ne V_0^3}.$$

Thus in transparent bodies for which *μ* is real, *C* and *B* differ in phase by $\pi/2$, and the reflected light is elliptically polarized, the major axis of the ellipse being in the plane of polarization of the incident light, so that in this case there is no rotation, but only elliptic polarization; when there is strong absorption so that *μ* contains an imaginary term, *C/B* will contain a real part so that the reflected light will be elliptically polarized, but the major axis is no longer in the plane of polarization of the incident light; we should thus have a rotation of the plane of polarization superposed on the elliptic polarization.

Zeeman's Effect.—Faraday, after discovering the effect of a magnetic field on the plane of polarization of light, made numerous experiments to see if such a field influenced the nature of the light emitted by a luminous body, but without success. In 1885 Fizez,⁴⁴ a Belgian physicist, noticed that the spectrum of a sodium flame was changed slightly in appearance by a magnetic field, but his observation does not seem to have attracted much attention, and was probably ascribed to secondary effects. In 1896 Zeeman⁴⁵ saw a distinct broadening of the lines of lithium and sodium when the flames containing salts of these metals were between the poles of a powerful electromagnet; following up this observation, he obtained some exceedingly remarkable and interesting results, of which those observed with the blue-green cadmium line may be taken as typical. He found that in a strong magnetic field, when the lines of force are parallel to the direction of propagation of the light, the line is split up into a doublet, the constituents of which are on opposite sides of the undisturbed position of the line, and that the light in the constituents of this doublet is circularly polarized, the rotation in the two lines being in opposite directions.

When the magnetic force is at right angles to the direction of propagation of the light, the line is resolved into a triplet, of which the middle line occupies the same position as the undisturbed line; all the constituents of this triplet are plane-polarized, the plane of polarization of the middle line being at right angles to the magnetic force, while the outside lines are polarized on a plane parallel to the lines of magnetic force. A great deal of light is thrown on this phenomenon by the following considerations due to H. A. Lorentz.⁴⁶

Let us consider an ion attracted to a centre of force by a force proportional to the distance, and acted on by a magnetic force parallel to the axis of z : then if m is the mass of the particle and e its charge, the equations of motion are

$$\begin{aligned} m \frac{d^2x}{dt^2} + ax &= -H \frac{dy}{dt}; \\ m \frac{d^2y}{dt^2} + ay &= H \frac{dx}{dt}; \\ m \frac{d^2z}{dt^2} + az &= 0. \end{aligned}$$

The solution of these equations is

$$\begin{aligned} x &= A \cos(p_1 t + \beta) + B \cos(p_2 t + \beta_1) \\ y &= A \sin(p_1 t + \beta) - B \sin(p_2 t + \beta_1) \\ z &= C \cos(pt + \gamma) \end{aligned}$$

where

$$\begin{aligned} a - mp_1^2 &= -He p_1 \\ a - mp_2^2 &= He p_2 \\ p^2 &= a/m, \end{aligned}$$

$$\text{or approximately } p_1 = p + \frac{1}{2} \frac{He}{m}, \quad p_2 = p - \frac{1}{2} \frac{He}{m}.$$

Thus the motion of the ion on the xy plane may be regarded as made up of two circular motions in opposite directions described with frequencies p_1 and p_2 respectively, while the motion along z has the period p , which is the frequency for all the vibrations when $H=0$. Now suppose that the cadmium line is due to the motion of such an ion; then if the magnetic force is along the direction of propagation, the vibration in this direction has its period unaltered, but since the direction of vibration is perpendicular to the wave front, it does not give rise to light. Thus we are left with the two circular motions in the wave front with frequencies p_1 and p_2 giving the circularly-polarized constituents of the doublet. Now suppose the magnetic force is at right angles to the direction of propagation of the light; then the vibration parallel to the magnetic force being in the wave front produces luminous effects and gives rise to a plane-polarized ray of undisturbed period (the middle line of the triplet), the plane of polarization being at right angles to the magnetic force. The components in the wave-front of the circular orbits at right angles to the magnetic force will be rectilinear motions of frequency p_1 and p_2 at right angles to the magnetic force—so that they will produce plane-polarized light, the plane of polarization being parallel to the magnetic force; these are the outer lines of the triplet.

If Zeeman's observations are interpreted from this point of view, the directions of rotation of the circularly-polarized light in the doublet observed along the lines of magnetic force show that the ions which produce the luminous vibrations are negatively electrified, while the measurement of the change of frequency due to the magnetic field shows that e/m is of the order 10^7 . This result is of great interest, as this is the order of the value of e/m in the negatively electrified particles which constitute the Cathode Rays (see ELECTRICITY, *Electric Discharge, Ency. Brit.* vol. xxviii.). Thus we infer that the "cathode particles" are found in bodies, even where not subject to the action of intense electrical fields, and are in fact an ordinary constituent of the molecule. Similar particles are found near an incandescent wire, and also near a metal plate illuminated by ultra-violet light.

A more extended study of the behaviour of the spectroscopic lines has afforded examples in which the effects produced by a magnet are more complicated than those we have described. Thus Preston⁴⁷ and Cornu⁴⁸ have shown that under the action of a transverse magnetic field one of the D lines splits up into four, and the other into six

lines; Preston has given many other examples of these quartets and sextets, and has shown that the change in the frequency, which, according to the simple theory indicated, should be the same for all lines, actually varies considerably from one line to another, many lines showing no appreciable displacement. The splitting up of a single line into a quartet or sextet indicates, from the point of view of the ion theory, that the line must have its origin in a system consisting of more than one ion. A single ion having only three degrees of freedom can only have three periods. When there is no magnetic force acting on the ion these periods are equal, but though under the action of a magnetic force they are separated, their number cannot be increased. When therefore we get four or more lines, the inference is that the system giving the lines must have at least four degrees of freedom, and therefore must consist of more than one ion. The theory of a system of ions mutually influencing each other shows, as we should expect, that the effects are more complex than in the case of a single ion, and that the change in the frequency is not necessarily the same for all systems. Preston⁴⁹ has proved that in some cases at any rate the change in the frequency of the different lines is of such a character that they can be grouped into series such that each line in the series has the same change in frequency for the same magnetic force, and moreover that homologous lines in the spectra of different metals belonging to the same group have the same change in frequency. Thus the behaviour of the spectrum in the magnetic field promises to throw great light on the nature of radiation, and perhaps on the constitution of the elements. The study of these effects has been greatly facilitated by the invention by Michelson⁵⁰ of the echelon spectroscope.

There are some interesting phenomena connected with the Zeeman effect which are more easily observed than the effect itself. Thus Cotton⁵¹ found that if we have two Bunsen flames A and B coloured by the same salt, the absorption of the light of one by the other is diminished if either is placed between the poles of a magnet: this is at once explained by the Zeeman effect, for the times of vibration of the molecules of the flame in the magnetic field are not the same as those of the other flame, and thus the absorption is diminished. Similar considerations explain the phenomenon observed by Egoroff and Georgiewsky,⁵² that the light emitted from a flame in a transverse field is partially polarized in a plane parallel to the magnetic force; and also Righi's⁵³ observation that if a sodium flame is placed in a longitudinal field between two crossed Nicols, and a ray of white light sent through one of the Nicols, then through the flame, and then through the second Nicol, the amount of light passing through the second Nicol is greater when the field is on than when it is off. For further information on the Zeeman effect the reader is referred to a valuable report by Voigt.⁵⁴

(J. J. T.)

Magnitnaya, a Cossack village of Russia, government of Orenburg, district Verkhneursk, on the Ural river. It was formerly a small frontier fort, but, owing to its advantageous position for trade with the Steppes, it has grown into a place of 10,100 inhabitants, and has an important cattle fair.

Magwe, a district in the Minbu division of Upper Burma, with an area of 3331 square miles and a population (1891) of 219,190, and (1901) 246,740, showing an increase of 12.38 per cent., and an average density of 74 inhabitants to the square mile. Magwe may be divided into two portions: the low, flat country in the Taungdwingyi subdivision, and the undulating high ground extending over the rest of the district. In Taungdwingyi the soil is rich, loamy, and extremely fertile. The plain is about 45 miles from north to south. At its southern extremity it is about 30 miles wide, and lessens in width to the north till it ends in a point at Natmauk. On the east are the Pegu Yomas, which at some points reach a height of 1500 feet. A number of streams run from this westwards to the Irrawaddy, and are used for navigation purposes. The Yin and the Pin, which form the northern boundary, are the chief, and receive the others. The only perennial stream is the Yanpè. Rice is the staple product, and considerable quantities are exported. Sesamum of very high quality, maize, and millet are also cultivated, as well as cotton in patches here and there over the whole district.

In this district are included the well-known Yenangyaung petroleum wells. The state wells have been leased to the Burma Oil Company. The amount of oil-bearing lands is estimated at 80 square miles, and the portion not leased to the company has been demarcated into blocks of one square mile, and offered on lease. The remaining land belongs to hereditary Burmese owners called *Tawinsu*, who dig wells and extract their oil by the rope and pulley system as they have always done. There are 319 square miles of forest reserves in the district. Lacquered wood trays, bowls and platters, and cart-wheels, are the only industries of any note in the district. There were 759 villages in the district, paying Rs.5,02,694 in 1898-99. Of a total of 1,864,209 acres, 343,765 were cultivated in that year, 255,360 were under forests, 154,898 acres were available for cultivation. There were 56,396 acres of current fallow, and 1,053,790 acres were not available for cultivation. The rainfall in the year 1898-99 was 27.74 inches. The maximum temperature rises to a little over 100° in the hot weather, and falls to an average minimum of 53° and 54° in the cold weather. In 1891 the population was made up of 216,931 Buddhists and Jains, 725 Mahommedans, 714 Hindus, 581 Karens and Chins, and 239 Christians, 142 of whom were natives. *Magwe*, the headquarters of the district, has a population of about 7000.

Mahadev Govind Ranade (1842-1901), native Indian lawyer, educationist, author, and reformer, was born on the 16th January 1842, at Niphad, in the Nasik district, his family having been for nine generations in state service. When his father was minister at Kolhapur, Mahadev attended the Anglo-vernacular school in that town, and joined the Elphinstone Institute in Bombay

at the age of fourteen. Along with Dr Ramkrishna Gopal Bhandarkar, Bal Mangesh Wagle, and Vaman Abaji Modak, all of whom distinguished themselves in after life, he appeared at the first examinations held by the Bombay University (established 1859). He took the degree of B.A. in 1862, M.A. in 1863, and LL.B. in 1866 with high distinction, and his teachers, Professor Harkness and Sir Alexander Grant, moved the University to award him special prizes. He was now known as the "Prince of Graduates," and was soon appointed assistant professor at the Elphinstone College, where his learned and thoughtful lectures drew some of the English professors to hear him. Having entered the Government service in 1866 as a translator, he became prime minister of Kolhapur state in 1868, assistant reporter to the Bombay High Court in 1869, presidency magistrate and then fourth judge of the Small Cause Court at Bombay in 1871, first-class sub-judge at Poona and then at Nasik and Dhulia in 1873, and judge of Poona Small Causes Court in 1884, after which, as special judge under the Deccan Agriculturists' Relief Act from 1887, he came into close contact with the difficulties of the agrarian classes. He was raised to be a judge of the Bombay High Court in 1893. In 1886 he was a member of the Finance Committee appointed to report on the expenditure, both imperial and provincial, with a view to retrenchment. This service won him the decoration of C.I.E. He became a member of the legislative council to the governor of Bombay in 1885, and occupied that position until he was raised to the High Court Bench. Being an energetic social reformer, he directed his efforts against infant marriages, the shaving of widows, the heavy cost of marriages and other social functions, and the caste restrictions on travelling abroad. He strenuously advocated widow remarriage and female education, and considered state legislation necessary for the social well-being of the country. He was the father of the Social Conference movement, which he supported till his death. In the political sphere he founded the Poona Sarvajanik Sabha, through which he frequently helped the Government with his sound advice. He was one of the originators of the Indian National Congress, and invariably attended its meetings. In Bombay University, where he held the offices of syndic and dean in arts, he displayed much organizing power and great intimacy with the needs of the student class. Himself a thorough Marathi scholar, he encouraged the translation of standard English works, and tried, with some success, to promote scholarships in vernacular languages by introducing them into the University curriculum. He was one of the managers of the Victoria Technical Institute. By birth a Chitpavan Brahmin, he was reared in the strictest tenets of Hinduism; but his deep religious feeling and trained intellect craved something higher and broader than he could find in the traditional forms and orthodox teaching of his race. The same spiritual want being felt by many enlightened Hindus, he joined with his friends, Dr Atmaram Pandurang, Bal Mangesh Wagle, and Vaman Abaji Modak, in founding a new sect in Bombay known as the "Pearthana Samaj." This community resembles, in all essential points, the Brahma Samaj of Bengal. Its principles of enlightened theism are based on the ancient Vedas. He married twice, his second wife being Ramabai, an enlightened and accomplished lady, who proved a fitting helpmate to him. He died childless, after a short illness, on the 16th January 1901, at the age of fifty-eight.

It was the task of Mr Ranade and his band of native reformers to guide and direct the rising force of general education in the second half of the 19th century in India in such a way as to preserve what was best in the past and adapt it to the present. He was therefore the friend, guide, and philosopher of all

sections and communities, parties and opinions, as he worked on lines of least resistance. It is no exaggeration to say that there was hardly any good movement in the Bombay Presidency, or more or less in the whole of India—political, social, religious, or industrial—that was not welded by his brain and nurtured by his spirit. He could therefore find no time to write any work on a large scale. Still, the annual addresses he delivered before the Social Conference for the fifteen years he was its general secretary, will long remain as landmarks of the intellect, moral courage, and high ideals of educated India, and he was a frequent contributor to the journal of the Poona Sarvajanic Sabha and the journal of the Bombay branch of the Royal Asiatic Society. His essays on Indian economics were published a few years before his death, and shortly before that event he issued a few chapters of the *History of the Mahrattas*—a work of much original research and thought, which had been left to him as a legacy by his pupil and friend Mr Justice K. T. Telang. (N. B. W.)

Mahallát, a small province of central Persia, situated between Kashán and Irák. It has a population of about 20,000, and pays a yearly revenue of about £2500. Until 1890 it was one of the five "central provinces" (the other four being Irák, Ferahán, Kezzáz, and Sávah), which were under a governor appointed by the Shah; since then it has formed part of the Isfahán government. It is traversed by the Anárbar or Kum river, and comprises the city of Mahallát, divided into upper and lower, or Rívkán and Zanjírván, and twenty-two flourishing villages. It was known in former times as Anár, the Anarus of Peutinger's tables. The city, capital of the province, is situated at an elevation of 5850 feet in 33° 51' N. and 50° 30' E., and has a population of about 9000.

Mahan, Alfred Thayer (1840—), American naval officer, strategist, and historian, was born in New York City on the 27th of September 1840. He graduated at the United States Naval Academy, Annapolis, Maryland, in 1859; became lieutenant in 1861, and served on the *Congress*, *Pocahontas*, *Seminole*, and *James Adger* during the Civil War, meanwhile acting as instructor at the Naval Academy for a year. At the close of the struggle he was made lieutenant-commander (commander in 1874), and subsequently, following the usual fortune of a naval officer, saw service in the Gulf of Mexico, the South Atlantic coast, the Pacific, and Asia, and did shore duty at Boston, New York, and Annapolis. In 1885 he became captain, and in 1886 president of the Naval War College at Newport, Rhode Island. Between 1889 and 1892 he was engaged in special service for the Bureau of Navigation, and in 1893 was made commander of the *Chicago*, of the European squadron. In 1896 he retired from active service, but was a member of the naval board of strategy during the war between the United States and Spain (1898), and the Peace Congress at The Hague in 1899. This long and varied service gave him extensive opportunities for observation, which he accompanied by constant study of naval authorities and reflection on the interpretation of the problems of maritime history. His first book was a modest and compact story of the doings in *The Gulf and Inland Waters* (1883), in a series of volumes by various writers, entitled *The Navy in the Civil War*; but in 1890 he suddenly acquired fame by the appearance of his masterly work entitled *The Influence of Sea-Power upon History, 1660-1783*. Having been impressed by the historian Mommsen's failure to allow for the influence of sea-power upon the career of Hannibal, he was led to make prolonged investigations of this general theme, especially for the period of time named in the title. The reception accorded the volume was instant and hearty; in England, in particular, it was deemed almost an epoch-making work, and was studied by naval specialists, Cabinet Ministers, and journalists, as well as by a large part of the general public. It was followed by *The Influence of Sea-Power upon the French*

Revolution and Empire (2 vols. 1892); *The Life of Nelson, The Embodiment of the Sea-Power of Great Britain* (1897); and *The Interest of America in Sea-Power, Present and Future* (a smaller and more fragmentary collection of chapters, 1897). The author's general aim in these works—some of which have been translated into French, German, and Japanese—was to make the consideration of maritime matters paramount to that of military, political, or economic movements, without, however, as he himself says, "divorcing them from their surroundings of cause and effect in general history, but seeking to show how they modified the latter, and were modified by them." He selected the year 1660 as the beginning of his narrative, as being the date when "the sailing-ship era, with its distinctive features, had fairly begun." The series as a whole has been accepted as finally authoritative, supplanting its predecessors of similar aim, and almost—in the words of Theodore Roosevelt—founding a new school of naval historical writing. Lesser works by the author are a *Life of Admiral Farragut* (1892), and a collection of articles grouped under the title of *Lessons from the Spanish War, and other Papers* (1899). Captain Mahan, in addition to other honours, received the degree of D.C.L. from Oxford, and that of LL.D. from Cambridge.

Mahanoy City, a borough of Schuylkill county, Pennsylvania, U.S.A., in the valley of Mahanoy river, in the eastern part of the state, at an altitude of 1240 feet. It has a level site, on which it is laid out regularly. It is on branches of the Lehigh Valley and the Philadelphia and Reading railways. Mahanoy is in the anthracite coal region, is surrounded by mines, and its industries are closely associated with mining and shipping coal. Population (1890), 11,286; (1900), 13,504, of whom 3877 were foreign-born.

Mahi Kantha, a political agency or collection of native states in India, within the Gujarat division of Bombay. The number of separate states is thirty-nine, many of which are under British administration. The only important one is Idar. Total area, 9300 square miles. Population (1881), 517,485; (1891), 581,568; (1901), 361,508, showing an increase of 12 per cent. between 1881 and 1891, but a decrease of 37·8 per cent. between 1891 and 1901; average density, 39 persons per square mile; estimated gross revenue, Rs.12,69,453, of which Rs.82,194 were expended on public works in 1897-98; tribute (mostly to the Gaekwar of Baroda), Rs.1,43,743; number of stipendiary police, 1723, maintained at a cost of Rs.1,89,126; number of schools, 105, with 6911 pupils. Many of the inhabitants belong to the wild tribes of Bhils and Kolis. In 1897 a metre-gauge railway was opened from Ahmedabad through Parantij to Ahmednagar; total length, 55 miles. At Sadra (population, 1839), is the Scott College for the education of the sons of chiefs on the lines of an English public school. In 1896-97 there were 35 boys, maintained at a total cost of Rs.3,135. There are also Anglo-vernacular schools at Sadra, Idar, and Mansa. The famine of 1899-1900 was severely felt in this tract.

Mahommed Ahmed [THE MAHDI] (1848-1885), the Sudanese tyrant, was born in Dongola in 1848. He was at first in the Egyptian Civil Service, but had disputes with his superior officials, and then took up slave-dealing. He settled on Abba Island, and acquired a reputation for sanctity which he used for stirring up disaffection with Egyptian rule. The Egyptian officials attempted to suppress him, but a force sent in 1881 for that purpose was resisted and defeated, and Mahommed Ahmed proclaimed himself the *Mahdi* (or Messiah), being

assisted by Abdullah (*q.v.*) as his *Khalifa* or vicegerent. The revolt in the Sudan spread, and the Mahdi was soon at the head of a powerful force; and 6000 Egyptian troops under Yusef Pasha, advancing from Fashoda, were nearly annihilated in June 1882. By the end of 1882 the whole of the Sudan south of Khartum was in rebellion, with the exception of the Bahr-el-Ghazal and the Equatorial Provinces. In November 1883 General Hicks's force of 10,000 men was destroyed at Kashgil, and in the same year the Mahdi's lieutenant, Osman Digna, raised the tribes in the eastern Sudan, and besieged Sinkat and Tokar, near Suakin, routing General Baker's force of 2500 men at El Teb. The military operations undertaken by Great Britain in face of this state of affairs are narrated under EGYPT. It need only be added here that General Gordon (*q.v.*) was entangled at Khartum, and that he was killed and Khartum captured by the Mahdists on 26th January 1885. The Mahdi himself died at Omdurman a few months later (22nd June 1885), and was succeeded in power by the Khalifa, Abdullah.

Mahommedan Law.—The Mahommedan law is always spoken of by Mahommedans as a sacred law, and as contained in the Koran. But the Koran itself could not have supplied the wants even of the comparatively rude tribes to whom it was first addressed. Still less has it proved sufficient to satisfy the requirements of successive generations. No doubt the great veneration which Mahommedans have for the Koran has caused them to be less progressive than members of other religious creeds. But in human affairs some change is inevitable, and the law of the Koran, like other sacred laws, has had to undergo the supplementary and transforming influence of custom and interpretation, though not of legislation. This direct method of changing the law by human agency, natural and simple as it appears to us, is scarcely acknowledged by Orientals even in the present day, except in the rare instances in which it has been forced upon them by Western authority. But besides custom and interpretation, another influence of a special kind has been brought to bear upon Mahommedan law. Besides those utterances which the Prophet himself announced as the inspired message of God, whatever he was supposed to have said and whatever he was supposed to have done have been relied upon as furnishing a rule for guidance. This tradition (*sunnah*) is only to be accepted if it can be traced up to a narrator at first hand, though it would be rash to say that the chain of evidence is always very strong. Mahommedans also, in support of a legal rule for which there is no direct authority, resort to the argument from analogy (*kias*). The principle involved in a rule for which authority can be quoted is extended so as to cover other analogous cases. There have also been accepted amongst Mahommedans, as authoritative, certain opinions on points of law delivered by those who were actual companions of the Prophet; these opinions are spoken of collectively under the name of *ijmaa*. Some of these methods of extending and modifying the law have produced changes which it would be very difficult to reconcile with a strict adherence to the language of the Koran.

Still, so far as it speaks at all, the text of the Koran remains the basis of Mahommedan law; and probably the Koran has had more practical effect on the lives and actions of those who accept it than any other revelation accepted by a portion of the human race as inspired. In comparison with the Jewish or Vedic scriptures, the Koran may be properly described as a modern book. We know exactly when, where, and how it was produced. The divine message was not written down by

the Prophet himself. Some passages may have been written down at the time they were delivered by his hearers; others were committed to memory. But a written collection was begun shortly after the Prophet's death (A.D. 632), and was completed within three years of that event. Fifteen years later, however, it being found that there were already considerable differences between the various copies of the Koran then in existence, a recension of the text was ordered, and measures were taken to destroy all previous copies as spurious. The authenticity of the text then constructed has never been seriously disputed. Whether in the operation of gathering together the scattered fragments from "palm leaves, skin, bladebones, and the hearts of men," and in preparing them for publication, the exact words used by the Prophet may not have undergone some change, it would be difficult to say. Having regard to the circumstances above stated, it is not surprising to find that the development of the Mahommedan law has not, in the great variety of peoples who have accepted the Mahommedan faith, proceeded always upon the same lines. Naturally also political differences have not been without their influence in these divergences of opinion, and of these political differences the most important of all was that which split the whole of Islam into the two great divisions of Sunnis and Shiah. These terms represent the two great parties into which Mahommedans were divided by the disputes as to the succession to the caliphate, which commenced very shortly after the death of the Prophet. These disputes culminated in the massacre of the descendants of Ali, the son-in-law of the Prophet, and the fourth caliph, by Yezid, who represented the rival or Omeyyad line. But the defeated party were not entirely destroyed, and, under the name of Shiah, have still maintained their authority. Other Mahommedans, to distinguish them, are called Sunnis, and, except in Persia, the Sunnis are the prevailing sect, the Shiah only being found elsewhere in scattered families. The dynastic quarrel which gave rise to the schism has long been dead; the memory of it only survives in the anniversary of the Mohurram, when Mahommedans still bewail the massacre of more than twelve hundred years ago. But the doctrinal differences involved in it still survive, and the legal systems of the Sunnis and Shiah differ in many important particulars. The Sunnis themselves are divided into four great sects or schools, each being called after the most conspicuous early exponent of its doctrines. These are the Hanafite school, called after Hanafa, who died in 702; the Malikite school, called after Malik-Ibn-Anas, who died in 812; the Shafaitic school, called after Mahommed-as-Shafi, who died in 826; and the Hanbalite school, called after Ahmad-Ibn-Hanbal, who died in 863.

Of the various existing forms of Mahommedan law, the one that has attained the greatest degree of coherence is that which prevails in India. Mahommedan law is administered in India to more than sixty millions of Mahommedans. If reference is made to the article HINDU LAW, it will be seen how it was that the Mahommedan law came to be administered by British courts of justice in India. The legislative enactments there quoted do not indicate exactly the limits of the application; practically the topics to which it is applied are the family relations, ownership, succession, and those religious questions in which civil rights are also involved. The Mahommedans of India generally are Sunnis of the Hanafite school. The two principal authorities on Mahommedan law to which recourse is had by the courts in India are the Hedaya and the Futwa Alumgiri. The Hedaya was translated into English by Mr Hamilton. The Futwa Alumgiri was compiled under the orders of the Emperor Aurungzib Alumgir. It is a

Sunnis and Shiah.

collection of the opinions of learned Mahommedans on points of law. It has not been translated, but it forms the basis of the *Digest of Mahommedan Law* compiled by Mr Neil Baillie. The Mahommedan law, like the Hindu law, is a personal law. It is essentially so in its nature. Persons of any other religion are to a large extent outside its pale. And in India, in civil matters, its application has been expressly limited to Mahommedans. At one time endeavour was made to administer the Mahommedan criminal law as the general territorial law of India, but it had constantly to be amended, and it was at length abolished and the penal code substituted. To be a Mahommedan, and so to claim to be governed by the Mohammedan law, it is necessary to profess the Mahommedan faith.

All that we find on the subject of intestate succession in the Koran are certain directions as to the shares which certain members of the family are to take in the estate of their deceased relative. So far as they go, these are rules of distribution—that is to say, they depend, not on consanguinity only, but on certain equitable considerations, by which rules founded on consanguinity are modified. But these latter rules, though nowhere laid down in the Koran, still play a large part in Mahommedan law. There can be no doubt that they represent the pre-existing Arabian custom, which it was not the intention of the Prophet to displace, but only to modify. The claimants under these rules take whatever is left after the specific shares assigned by the Koran to individual members of the family have been satisfied; if in any case there are no such shares, they take the whole. The Arabic term for this class of heirs is *asabah*, which literally means persons connected by a ligament. The term used by English writers is “residuaries,” but this description of them has the disadvantage that it entirely loses sight of the connexion on which the claim to succeed is based. They would be more correctly described as the “agnates” of the deceased, but the term “residuaries” is too firmly established to be displaced. Those persons who take a share of the property, under the specific rules laid down in the Koran, we call “sharers,” and this word has acquired a technical meaning; it is not used to describe those who can claim a portion of the estate in any other way. It is hardly likely that females, or relatives through females, had any claim to the succession under any Arabian custom, nor, except so far as they are made sharers, are they recognized by the Koran as having a title to succeed. The proper description of this class of persons is *zavi-ul-arham*, *i.e.*, “uterine kindred,” and they have, in default of other heirs, established a claim to succeed. English writers have erroneously called them “distant kindred,” but distance has nothing to do with the matter.

There is no right of primogeniture under Mahommedan law; there is a general preference of males over females, and if males and females take together as residuaries by an express provision of the Koran, each male takes as much as two females. Females are also expressly forbidden by the Koran to take more than two-thirds of the property; but in the application of these two rules the shares of the mother and the wife are not included. No person can claim to take any portion of the property who traces his relationship to the deceased through a living person, but this rule does not apply to brothers and sisters whose mother is alive. If several persons all stand in the same degree of relationship to the deceased, they take equally, *per caput* and not *per stirpem*.

It will now be convenient to state the rules for finding which of the agnates take as residuaries of the deceased. These are, in ordinary circumstances, the male agnates only, and the rule in question depends upon a classification

of the male agnates which is common in other parts of the world. Every family consisting of several generations of male agnates may be broken up into groups, each of which has a separate common ancestor of its own. Thus, suppose A to be the person from whom the descent is to be traced. A belongs to a large group of persons, all of whom are males descended from a common ancestor D. But A and his or her own male descendants form a smaller group, which we may call the group A. This is the first class of male agnates of A. Then suppose A to be the son or daughter of B, excluding those who are descendants of A, and as such included in the first class, the remaining male descendants of B will form the second class of male agnates of A. In like manner we get a third class of male agnates of A who are descendants of C, excluding those who are descendants of A or B; and a fourth class of male agnates of A who are descendants of D, excluding those who are descendants of A, B, or C. This classification can obviously be carried through as many generations as we please. Mahommedan lawyers adopt this classification with only one difference. Between the first and second classes they interpose a class consisting entirely of the direct male ancestors, which they call the “root,” so that the male descendants of A (the person whose heirs are in question) would be the first class of residuaries. B, C, D, &c. would be the second class of residuaries; the male descendants of B, other than the descendants of A, would be the third class of residuaries; the male descendants of C, other than the descendants of B and A, would be the fourth class of residuaries, and so on. In order to find the residuaries who are to succeed, we have only to take the classes in their order, and of the highest class which is represented to select the nearest to the deceased. If there are several who are equidistant, they will take equally *per caput*.

The sharers are, of course, those to whom a share is assigned by the Koran. They are (1) the father, (2) lineal male ancestors, whom Mahommedans call the “true grandfathers,” (3) uterine half-brothers, *i.e.*, the half-brothers by the mother, (4) daughters, (5) daughters of a son, or other direct male descendant, whom we call daughters of a son how low and soever, (6) the mother, (7) true grandmothers, *i.e.*, female ancestors into whose line no male except a lineal male ancestor enters, (8) full sisters, (9) consanguine half-sisters, *i.e.*, half-sisters by the father, (10) uterine half-sisters, (11) the husband, (12) the wives. The right to a share and the amount of it depends upon the state of the family. Under Mahommedan law not only, as elsewhere, the nearer relative excludes the more remote, but there are special rules of total or partial exclusion arising out of the equitable considerations upon which all rules of distribution are based.

These rules are best shown by taking the case of each member of the family in turn, and at the same time it will be useful to explain the general position of each member. First, the sons. They take no share, but they are first in the first class of residuaries, and their position is a very strong one; they exclude entirely sisters and daughters from a share, and they reduce considerably the shares of the husband, the widows, and the mother. The position of the other male descendants is very similar to that of the sons. They are not sharers; they are residuaries of the first class, and will take as such if the intermediate persons are dead. They reduce the shares of some of the sharers, but not to the same extent as the sons. The father is a residuary of the second class, and the first in that class. But he is also a sharer, and as such is entitled to a share of one-sixth. He can take in both capacities. The father's father is also a residuary of

the second class, and he is a sharer, entitled to a share of one-sixth, but of course he cannot take either as sharer or residuary if the father is alive. The position of any true grandfather is analogous. An only daughter takes as sharer one-half of the property, two or more daughters take one-third between them. But sons exclude daughters from a share, and they would get nothing. Naturally this was considered unjust, and a remedy has been found by making the daughters what are called "residuaries in right of their brothers," each daughter taking half of what a son takes. The mother gets a share of one-sixth when there is a child of the deceased, or a child of any son how low and soever; also when there are two or more brothers or sisters. In any other case her share is one-third. If, however, the wife, or the husband (as the case may be), and the father are alive, the share of the mother is only one-third of what remains after deducting the share of the husband or the wife. The brother is never a sharer. He is a residuary of the third class, and he excludes some sharers. The daughters of a son how low and soever get a share of two-thirds between them if there are several; if there is only one she gets one-half. But the daughters of a son are excluded by any direct male descendant who is nearer to the deceased than themselves, or at the same distance from him. If, however, they are excluded by a person who is at the same distance from the deceased as themselves, Mahomedan lawyers again say that they come in as residuaries in right of that person, each female as usual taking half as much as each male. Of course the daughters of a son may also be excluded by the daughters having exhausted the two-thirds allotted to females. A single sister takes a share of one-half; several sisters take two-thirds between them. Sisters are excluded from a share by any residuary of the first class, and their own brothers also exclude them, but in the latter case they take as residuaries in right of their brothers, each sister taking half what a brother takes. So, again, the sisters may be excluded from a share by the daughters or daughters of sons having exhausted the two-thirds allotted to females, and the residue would go to the nearest male agnate—that is, the uncle or the nephew of the deceased, or some more distant relative. To prevent this Mahomedan lawyers say that in this case the sisters are residuaries, basing their assertion upon a somewhat vague tradition. The share of the husband in the property of the wife is one-fourth if there are surviving children, one-half if there are none. The share of the widow in the property of her deceased husband is one-eighth if there are surviving children, one-fourth if there are not. The nearest true grandmother takes a share of one-sixth. If there are several equidistant, they take one-sixth between them. The uterine half-brothers take a share of one-third when there is only one, but they are excluded by any direct descendant and by any direct male ascendant. Uterine half-sisters are in the same position as uterine half-brothers. Consanguine half-brothers are residuaries of the same class as brothers, but only take in default of full brothers. Consanguine half-sisters take a share of two-thirds, or if there is only one she takes a share of one-half. But if there is a full sister also, the full sister takes one-half, and the consanguine sisters one-sixth between them. The consanguine half-sisters, like the full sisters, are excluded from a share by the children and the father of the deceased, and also by full brothers and consanguine brothers; but in the last case they come in again as residuaries, taking half what a brother takes.

The sharers must, of course, unless excluded, be all satisfied before anything is taken by the residuaries. But the sharers may not only exhaust the property;

there may not be enough to satisfy all the claimants. Thus, if a man died leaving a wife, a mother, and two daughters, the shares are one-fourth, one-sixth, and two-thirds, and the sum of the shares being greater than unity, they cannot all be satisfied. The difficulty is met by decreasing the shares rateably, in other words, by increasing the common denominator of the fractions so as to produce unity; hence the process is called the "increase." The converse case arises when the shares of the sharers do not exhaust the property, but there are no residuaries to take what remains. It has been doubted whether the residue does not fall to the Government as *bona vacantia*. But it is now settled that the surplus is to be divided rateably amongst the sharers in proportion to their shares. The process is called the "return." The husband and the wife are excluded from the benefit of the return. If there are no sharers, the whole estate will go to the residuaries. If there are neither sharers nor residuaries, it will go to the (so-called) distant kindred. Their claim is strong on equitable grounds, as some of them are very near relations; such, for example, as a daughter's children or a sister's children. Nevertheless their claim has been doubted, and it must be admitted that there is no very clear ground upon which it can be based. They are not mentioned as sharers in the Koran, and it is not very clear how, as cognates, they could have been recognized by any ancient Arabian custom. However, their claim is now well established, and, in default of both sharers and residuaries, they succeed on a plan somewhat resembling that on which male agnates are classified as residuaries. If all the claimants fail the property goes to the Government, but there is one peculiar case. Supposing a man dies leaving a widow, or a woman dies leaving a husband, and no other relative. There is then a residue and no one whatever to take it, as the husband and wife are excluded from the return. Strictly speaking it would fall to the Government as *bona vacantia*, but the claim is never made, and would now be considered as obsolete, the husband or wife being allowed to take the property.

Under Mahomedan law there are certain grounds upon which a person who would otherwise succeed as heir to a deceased person would be disqualified. These grounds are—(1) that the claimant slew the deceased by an act which, under Mahomedan law, would entail expiation or retaliation, and this would include homicide by misadventure; (2) that the claimant is a slave; (3) that he is an infidel, *i.e.*, not of the Mahomedan faith. The second impediment cannot now have any application in India; the third has been removed by Act 21 of 1850. There is a rule of Mahomedan law that if two persons die in circumstances which render it impossible to determine which died first, as, for example, if both went down in the same ship, for the purposes of succession it is to be assumed that both died simultaneously.

Mahomedan lawyers appear always to have recognized the validity of wills, and they are said to be recognized by a passage in the Koran. But the power of testamentary disposition is restricted within very narrow limits. It only extends to one-third of the property after the payment of debts and funeral expenses. There is no hint of this restriction in the Koran, and it rests upon tradition. If the one-third has been exceeded the legacies must be reduced rateably. The heirs, however, by assenting to the legacies, may render them valid even though they exceed the prescribed amount. There is no restriction as to the form of making a will; it may be either oral or written. A legacy cannot be given to an heir. Mahomedan law contains some very simple and wise provisions for preventing the reckless and often unjust dispositions of property which persons are apt to make upon the approach of death. A

Testamentary succession.

man who is "sick," that is, who is suffering from illness which ends in death, can only give away one-third of his property; and if he has also made a will containing legacies, the gifts and the legacies must be added together in the computation of the disposable one-third. So long as slaves had a money value, the value of the slaves liberated by a man on his deathbed was also included, which reminds us of the *Lex Furia Caninia* of the Roman law. Another transaction by which the restriction on the testamentary power might be eluded is that called *mohabat*. By this is meant a transaction in the form of a sale, but which, from the inadequacy of the price named, is obviously intended as a gift. If such a transaction is entered into during "sickness," the loss to the estate would have to be reckoned in computing the disposable one-third. But the *mohabat* transaction takes precedence of legacies. Another obvious mode of eluding the restriction on the testamentary power is the acknowledgment by a man on his deathbed of a fictitious debt; and it would seem that such acknowledgments ought to have been put under restriction. But Mahomedans, like other Orientals, have a useful, though possibly a superstitious, dread of leaving the debts of a deceased person unpaid, and it is this, no doubt, which has prevented their questioning the deathbed acknowledgment of a debt, even though there is every reason to believe it to be fictitious. All that has been done is to prescribe that debts of health should be paid before debts of sickness, and that debts cannot be acknowledged by a sick man in favour of an heir.

When a Mahomedan dies, the funeral expenses and the creditors must first be paid; then the legatees, then the claims of the sharers, and, lastly, those of the residuaries; or, if there are neither sharers nor residuaries, those of the (so-called) distant kindred. The administration of the estate need present no difficulties if there are no disputes, and if there is some one empowered to take possession of the property, to get in the debts, to satisfy the creditors, and distribute the assets amongst the various claimants; and such a person may be appointed by a Mahomedan in his will, who will perform these duties. He is called a *wasi*, and he is in a position very similar to an executor under English law. But if there is no *wasi*, even if there are no disputes, there may be a good deal of trouble. It would have been in accordance with the spirit of Mahomedan law, and with general principles of equity, if an officer of the courts established under British rule had been regularly empowered to take possession of the property, and to take such measures as were necessary to ensure all the claimants being satisfied in their proper order. But this view of their powers has not been taken by the courts in India; recently, however, they have been enabled by legislation to grant the power of administering the estate to a single person.

There is scarcely any part of Europe or Asia where the creation of fictitious relationships is altogether unknown.

In many cases the object of the creation is simply to obtain an heir. This is the object of adoption amongst modern Hindus, and it is this, no doubt, which has led some persons to speak of Hindu adoption as a rudimentary will. But adoption, as such, has never obtained a footing in Mahomedan law. The fictitious relationships which that law recognizes are based upon a different idea. There was in early times a widespread notion that every man must belong to some family either as a freeman or a slave. The family to which a slave belongs is always that of his owner, and that of a freeman is generally indicated by his birth. But a liberated slave has no family, at least no recognized family; and as he cannot stand alone, it was necessary to attach him to some family. Now, just

as in Roman law the freedman became a member of his master's family under the relationship of *patronus* and *cliens*, so in Mahomedan law a liberated slave becomes a member of the master's family under the relationship called *mawalat*. The object, of course, was to make the master's family liable for the consequences of the wrongful acts of the freed slave. As a compensation for the liability undertaken by the master's family, in default of residuaries of the slave's own blood (who can only be his own direct descendants), the master's family are entitled to succeed as what are called "residuaries for special cause." Of course the relationship of master and slave cannot now be created, and it is scarcely probable that any case of inheritance could arise in which it came into question. The relationship of *mawalat* may, under Mahomedan law, also be created in a case where a freeman is converted to Islam. From a Mahomedan point of view he then stands alone, and would be required to attach himself to some Mahomedan family. The form of the transaction exactly indicates the nature of it. The party wishing to attach himself says to the person ready to receive him, "Thou art my kinsman, and shalt be my successor after my death, paying for me any fine or ransom to which I may be liable." In this case also the family of the person who receives the convert is entitled, in default of other residuaries, to succeed to him as "residuaries for special cause." But this transaction can have no meaning under English law, which does not recognize the joint responsibility of the family, and it is therefore also obsolete. In the case of *mawalat* the rights of the persons concerned are not reciprocal. The person received gains no right of inheritance in the family into which he enters, and incurs no responsibility for their acts. An important part may still be played in Mahomedan law by the creation of relationships by acknowledgment. Any such relationship may be created, provided that the parentage of the person acknowledged is unknown; a person of known parentage cannot be acknowledged. The age, sex, and condition of the person acknowledged must also be such that the relationship is not an impossible one; for, as was said in the Roman law, *fictio naturam imitatur*. The relationship thus constituted is, in the case of a father, mother, child, or wife, complete, and must be treated for all purposes as having a real existence. But in any other case the acknowledgment, although good as between the parties thereto, has no effect upon the rights of other parties. The acknowledgment which we have just been considering contemplates the possibility at any rate, and in most cases the certainty, that the relationship is entirely fictitious, and has no connexion with any rule of evidence in whatever sense the term is understood. But there is a rule of Mahomedan law that, in cases where the paternity of a child is in dispute, the acknowledgment of the child by the father is conclusive. Whether this would now be maintained in face of the Evidence Act, 1870, which deals with cases of conclusive evidence, and expressly repeals all previously existing rules of evidence, may be doubtful.

Marriage is a transaction based upon consent between a man and a woman, or between persons entitled to represent them. The result of the transaction is that certain family relationships involving legal *Marriage.* rights and duties are created by the law, and these are not wholly under the control of the parties. But as to some of them, to some extent they may be regulated by agreement, and it is customary amongst Mahomedans at the time of a marriage to come to such an agreement. The only condition necessary to the constituting of a valid marriage between persons of full age is the consent of the parties. It is, however, the practice to conclude the transaction in the presence of two males, or one male and

two female witnesses ; and the omission of this formality would always throw a doubt upon the intention of the parties finally to conclude a marriage. It is even said that the absence of such witnesses would justify a judge in annulling the marriage. Minors of either sex may be given in marriage by their guardian, and the transaction will be irrevocable if the guardian be the father or any direct male ascendant. In any other case the marriage may be repudiated when the minor arrives at the age of puberty, but the repudiation is not effectual until confirmed by a judge of the civil court. A marriage may be conducted through agents. A woman can have only one husband ; a man can have four wives ; if he married a fifth the marriage would be annulled by a judge on the application of the woman. Mahommedans have a table of prohibited degrees within which parties cannot marry not very dissimilar to that in force in Great Britain. Nor can a man be married at the same time to two women nearly related to each other, as to two sisters. It is also considered that if a woman take a child to nurse she contracts a sort of maternity towards it, and that if a boy and girl are nursed by the same woman they become brother and sister, and, in a general way, it is said "that whatever is prohibited in consanguinity is prohibited in fosterage"; but it is doubtful whether the law goes so far. The widow, or a divorced woman, is not allowed to marry again during her *iddut*. This is a period of chastity which a woman is bound to observe in order to avoid confusion of issue. If she is pregnant it lasts until the child is born ; if not, then in case of divorce it lasts through three periods of menstruation ; if she is a widow it lasts for four months and ten days. A Mahommedan man cannot marry an idolatress, but Jews and Christians are not thereby excluded, because, although infidels, they are not idolatresses. A woman is forbidden by Mahommedan law to marry any one who is not a Mahommedan ; but if the marriage took place in conformity with the Act of 1872 it might be valid, if it amounted to a repudiation by the woman of her Mahommedanism. It is important to remember, when considering the validity of a Mahommedan marriage, that a distinction is drawn between marriages which are simply void (*batal*) and those which can only be annulled by judicial decision (*farid*), for such a decision has no retrospective effect, so that the children already born are legitimate ; and if no step is taken to obtain such a decision during the existence of the marriage, it cannot be questioned afterwards. What marriages are absolutely void, and what are only capable of being declared void, is not very clearly settled, but the evident leaning of Mahommedan law is against absolute invalidity, and there is strong authority for the opinion that no marriages are absolutely void except a marriage by a woman who has a husband living and such as are declared to be incestuous.

A Mahommedan has the absolute right to divorce his wife whenever he pleases without assigning any reason whatever for doing so. There are, however, **Divorce.** very strong social reasons which have considerable influence in restraining the arbitrary exercise of the power. The power to divorce remains notwithstanding any formal promise by the husband not to exercise it, and it is even said that a divorce pronounced in a state of intoxication, or by a slip of the tongue, or under coercion, is valid. The divorce can, however, be revoked by the husband, but not after it has been three times pronounced, or after the *iddut* has been passed by the woman. Nor can the husband remarry his divorced wife unless she has been again married, and has been again divorced or become a widow, and the intermediate marriage must have been consummated. The power to divorce a wife may be entrusted by the husband to an agent acting on his behalf,

and this contrivance is sometimes made use of to enable a woman's friends to rid her of her husband if he ill-treats her. The husband may even empower the wife to divorce herself. If the husband or the wife should happen to die whilst the divorce is still revocable, he or she will inherit ; and even a triple repudiation pronounced during "sickness," that is death-sickness, will not deprive the woman of her inheritance if the *iddut* has not been passed. Of course there is nothing to prevent the husband and the wife from agreeing to a divorce, and to the terms on which it is to take place, and such an arrangement is very common. The treatment of the wife by the husband is not a ground upon which the marriage can be dissolved, but the impotence of the husband is a ground of dissolution. The courts in India consider that they have the power under Mahommedan law to grant a decree for the restitution of conjugal rights.

Dower in Mahommedan law is in the nature of a gift from the husband to the wife on the marriage, like the *donatio propter nuptias* of the Roman law, or the *morgengabe* of Teutonic nations. It may be **Dower.** either "prompt," that is, payable at once, or the payment of it may be deferred, or it may be partly the one and partly the other. The amount of the dower and the time of payment ought to be settled by agreement before the marriage takes place ; if this is not done there is some trouble in ascertaining the rights of the parties. It seems clear that a woman is entitled as a matter of right to what is called a "proper" dower. If the dower is payable at once the woman may, before consummation, refuse herself to her husband unless it is paid ; whether she can do so after consummation is doubtful. If the husband capriciously repudiates the wife before consummation, or the wife before consummation repudiates the husband for his misconduct, then half the dower agreed on must be paid. If it is her misconduct which has caused the repudiation, she is not entitled to anything. Deferred dower becomes payable on the dissolution of the marriage either by death or by divorce. Probably a judge, when called upon to dissolve or annul a marriage, could make reasonable stipulations as to the dower. The dower is the wife's own property, and, as the wife is entirely independent of the husband in regard to her property, she can sue him or his representatives for the dower like any other creditor. Mahommedans generally before marriage enter into a formal contract which regulates not only the dower, but various other matters under the control of the parties, such as the visits the wife is to pay or receive, the amount of liberty which she is to have, and so forth.

The right of pre-emption under Mahommedan law is the right of a third person, in certain circumstances, to step in and take the place of a buyer, at the same price and on the same conditions as the buyer has purchased. It applies only to the purchase **Pre-emption.** of real property, and it can only be exercised upon one of the three following grounds:—(1) That the claimant is owner of property contiguous to that sold ; (2) That he is a co-sharer in the property of which a share is being sold ; (3) that he is a participator in some right over the property, such, for example, as a right of way over it. The claimant must announce his claim as soon as he hears of the sale, and he must follow up this announcement by a further claim in the presence of witnesses and of the seller, or, if possession has been transferred, of the buyer.

Mahommedan law, so far as it is administered by the courts of British India for Sunnis of the Hanafite school—that is, for the great bulk of Mahommedans—has attained a fair degree of precision, owing to the care bestowed on their decisions by the judges of those courts, and the assistance derived from Mahommedan lawyers.

But much difficulty is experienced as soon as we come to deal with Mahommedans of any other description. No doubt in India any clearly-established custom prevalent amongst a well-defined body of persons would be recognized, or any rule of law founded upon texts which they accepted as authoritative. But it is not always easy to determine when these conditions have been satisfied. And to allow Mahommedans to set up a standard of rights and duties different from that of the bulk of their correlative without this proof would lead not only to confusion but injustice. There is the further difficulty that Mahommedan law, as applied to any Mahommedans except those of the Hanafite school, has as yet been comparatively little studied by modern lawyers, so that very little that is certain can be said about it. There is, however, a considerable

Shiah system.

body of Shiahs in India whose legal system undoubtedly differs in some material particulars from that of the Sunnis. The Mahommedans of Oudh are generally Shiahs, and Shiah families, mostly of Persian descent, are to be found in other parts of India. The following points seem clear. A marriage which the parties agree shall last for a fixed time, even for a few hours only, is a valid marriage, and at the expiration of the time agreed on the marriage ceases to exist. The relatives of the deceased, whether male or female, and whether tracing their connexion through males or females, may be sharers or residuaries. Both as sharers and residuaries the children can claim to take the place of their parents in the succession upon the principle of what we call representation. If there are parents or descendants of the deceased, and the sharers do not exhaust the property, the surplus is distributed amongst the sharers of that class in proportion to their shares. If the property is not sufficient to pay in full the shares of all the sharers, the shares do not abate rateably; e.g., as between daughters and the parents, or the husband, or the wife of the deceased, the whole deduction is made from the daughters' share.

Maidenhead, a municipal borough and market-town in the Wokingham parliamentary division of Berkshire, England, on the Thames, 24½ miles west of London by rail. A technical school has been opened; the remains of a Roman villa have been discovered in the neighbourhood; a richly-wooded recreation ground (14 acres) and Kidwells Park (12 acres) have been presented to the town. Population (1881), 8,220; (1901), 12,980.

Maidstone, a municipal and parliamentary borough and the county town of Kent, England, in the Medway parliamentary division of the county, 47 miles south-south-east of London by rail, on the river Medway. It is the headquarters of a military district. The Bently Art Gallery was presented to the town in 1890, and the West Kent and General Hospital extended. There are an oil mill, rope, sacking, and twine factories, and cement, lime, and brick works. Famous hop gardens are in the district. Population (1881), 29,623; (1901), 33,516.

Maihar, a native state of Central India, in the Baghelkhand agency. Area, about 400 square miles. Population (1881), 71,709; (1891), 77,546, showing an increase of 8·1 per cent. The estimated revenue is Rs.71,000. The number of schools in 1897-98 was 8, with 247 pupils. The chief, whose title is Raja, is a Hindu of the Jogi sect. The state suffered severely from famine in 1896-97. The

town of MAIHAR (about 6500) is on the East Indian railway, 97 miles north of Jubbulpore.

Maimansingh. See MYMENSING.

Maine, the most north-easterly state of the American Union, and by far the largest of the New England states. The development of its resources since 1880 has not produced much change in the tendency of its population, which in 1890 was 661,086, and in 1900 was 694,466, an increase of 5 per cent. The total land surface of the state is about 29,895 square miles, and the average number of persons to the square mile was therefore 22·1 in 1890 and 23·2 in 1900. The death-rate in 1900 was 17·5. There were in 1900 twenty-five places having a population of more than 4000 inhabitants each and a total population of 251,685. The urban population in 1900, including in this class all persons in cities of more than 8000 inhabitants, was 164,639, or 23·7 per cent. of the total population, as compared with 130,346, or 19·7 per cent., in 1890. There were in 1900 nine of such cities, of which the most important, with their population, were: Portland (50,145), Lewiston (23,761), and Bangor (21,850). Of the total population in 1900, 350,995 (50·5 per cent.) were males and 343,471 were females; 601,136 (86·6 per cent.) were native-born, and 93,330 foreign-born; 692,226 (99·7 per cent.) were white, and 2240 (only 0·3 per cent.) coloured, including 1319 negroes, 119 Chinese, 4 Japanese, and 798 Indians. Of the total native-born population, it is calculated that 588,000 were Maine-born. There were 215,000 Maine-born people residing in other states. Of the total foreign-born, it is estimated that 53,000 were from the adjacent British provinces, and 11,500 from Ireland. The French-speaking population numbers about 50,000. They are of two quite distinct classes. One, numbering about 15,000, includes those who became citizens by the establishment of the northern boundary in 1842, and their descendants. They are largely of Acadian stock, are good citizens, feeling pride in their allegiance to the Union, and are coming more and more under the influence of the public schools. The state has established among them a well-appointed training school for teachers, conducted in the English language, the graduates of which render excellent service in the common schools. The other class is of French-Canadian immigrants, who find profitable employment in the manufacturing centres. With their savings they are building homes and buying abandoned farms. Very few have any desire to return to Canada, or any thought of establishing a "French Empire" in New England. At the same time, their numbers are felt in the communities where they reside, and as they show a disposition to become naturalized citizens, their political weight is considerable. Parochial schools are encouraged by their Church, the Roman Catholic, but the young people incline towards the public schools. The colony of Swedes established by the state near its north-eastern border in 1869 has proved in every way successful. These people, who number about 2000, are already in sympathy with American institutions, and their steady increase will go far to make good the loss by removal of some of the best native stock. The shores of Maine, as also its lakes and woods, have become great resorts for tourists and summer residents. It is estimated that these sojourners number 250,000 annually, and that their expenditure in the state amounts to \$12,000,000.

Public Works.—The United States Government has done much in deepening harbours and river channels, removing obstructions, and marking the approaches by lights, buoys, and beacons. The state has provided for a thorough topographical survey, in co-operation with the surveys by the United States. The general government has also given special attention to coast and harbour defences. Obsolete works have been replaced by modern fortifica-

tions of the most effective order. The defences of the approaches to Portland have been also greatly extended, so as perfectly to guard the magnificent anchorage-grounds behind the sheltering islands. A coaling station and naval rendezvous has been established on Frenchman's Bay, east of Mount Desert.

Property and Taxes.—The state assessors' valuation of property for purposes of taxation for 1900 was \$287,691,790, of which the real estate was 78 per cent., and the personal, 22. The annual increase in the value of real estate during several preceding years averaged over \$3,000,000, mostly in buildings and improvements. The increase in personal property was at a much lower rate, and chiefly in value of live stock. The state debt in 1900 amounted to \$2,153,000. The state tax is 2½ mills on the dollar, while the average local rate is ten times this.

Banks, &c.—There were in 1900 thirty-two national banks, with a capital of \$10,971,000, and for that year surplus and undivided profits of \$4,260,722, and total resources of \$41,992,070; fifty-one savings banks, with deposits of \$71,076,212, by 177,600 depositors; seventeen trust companies, with capital stock of \$1,651,400, and total resources of \$11,802,257; thirty-two loan and building associations, with total resources of \$2,975,766. The legal rate of interest is 6 per cent., but safe investments do not often return more than 4 or 5 per cent. There is no legal limit to rate by contract.

Industries.—The various branches of agriculture still constitute the leading industry of the state. In 1900 there were 59,299 farms, containing 6,299,946 acres, of which about 38 per cent. was improved land. The total value of farm property was \$122,410,904, made up as follows: land, improvements, and buildings, \$96,502,150; implements and machinery, \$8,802,720; live stock, \$17,106,034. The total value of farm products for the preceding year was \$37,113,469. The number and value of the most important farm animals in 1900 were: 173,592 dairy cows, \$5,060,048; 165,255 other neat cattle, \$2,525,497; 106,299 horses, \$7,058,989; 252,213 sheep (excluding lambs), \$751,777; 79,018 swine, \$516,015. The principal crops and their values in 1899 were: oats, \$1,374,573; hay and forage, \$10,641,546; potatoes, \$3,711,999; miscellaneous vegetables, \$1,207,075; and orchard fruits, \$833,634.

Mechanical industries have grown in extent and in productive power. General good feeling between employers and workmen prevailing, strikes have not been common. Shipbuilding has revived. It is now carried on at advantageous points, with concentration of capital and large use of machinery, and is chiefly directed to vessels for heavy domestic trade. Building is going on at the rate of 5000 tons a month. Iron ships are successfully built at Bath. The Bath Iron Works have a continuous line of contracts for Government ships, and keep 1000 men at work all the year. In the cotton factories the employés are mostly French-Canadians, in the woollen factories mostly natives. There are two flourishing plush factories, using the hair of the Angora goat of Asiatic Turkey, and California and Oregon, and of the llama of South America, with some native wools. These goods find a large market in Russia and Japan. There are quarries of granite, of lime, and of slate. Ice is a staple product, amounting in some years to over 3,000,000 tons. A growing industry is sardine-packing, largely carried on in the south-eastern part of the state. The general statistics of manufactures are shown by the following table:—

	1890.	1900.	Per cent. of Increase.
Number of establishments	5,010	6,702	33·8
Capital	\$80,419,809	\$122,918,826	52·8
Salaried officials, clerks, &c.	5,406 ¹	3,329	58·4 ²
Salaries	\$3,563,635 ¹	\$3,171,433	11·0 ²
Wage-earners (average number)	70,374	74,816	6·3
Total wages	\$22,962,582	\$28,527,849	24·2
Miscellaneous expenses	\$5,394,694	\$7,774,216	44·1
Cost of materials	\$51,520,589	\$68,863,408	33·7
Value of products	\$95,689,500	\$127,361,485	33·1

The following table shows statistics of six leading industries:—

Industry.	Number of Establishments.	Wage-earners.	Value of Products.
Boots and shoes	48	6,432	\$12,295,847
Cotton goods	15	13,723	14,631,086
Fish, canning and preserving	117	5,567	4,779,733
Lumber and timber products	838	6,834	13,489,401
Paper and wood pulp	35	4,851	13,223,275
Wool manufactures	79	7,155	13,412,784

¹ Includes proprietors and firm members, with their salaries.

² Decrease.

Lumber and Wood Pulp.—There are 21,000 square miles of forest. The pine region of the south-west is well cut over, and owners of these lands are taking pains to promote new growth. Spruce is now the chief tree. This is worked into long lumber to the extent of 250,000,000 feet a year, and into pulp for paper to the extent of 350,000,000 feet. In the former great advance has been made in the process of manufacture, chiefly by economies in machinery and motive power. The pulp industry has advanced rapidly. Large tracts of timber lands have been bought and extensive mills built. Some of the finest of book-paper is made here. The advent of this immense pulp industry has given rise to fears of the rapid destruction of the forests, with serious detriment to natural conditions, such as rainfall, water-storage, climate, &c.; but the necessity of securing a long supply of material for such costly plants will lead to the adoption of rigid and intelligent economy, so that, as one consequence of the pulp operations, a system of forestry will supersede the reckless waste of old lumber operations under "permits" from distant owners.

Railways.—The total mileage of steam railways in Maine in 1901 was 1919 miles. The capitalization of these within the state is \$63,955,121. The gross earnings within the state for the year ending 30th June 1901 amounted to \$10,930,003. Numerous electric street railways have been constructed, with a total mileage on 30th June 1901 of 286 miles, and an investment value of about eight million dollars. The gross earnings for the year were over one million dollars; and the number of passengers carried was nearly twenty millions. The principal railway systems are the Boston and Maine, Maine Central, Grand Trunk, Canadian Pacific, Bangor and Aroostook, Rumford Falls, and Washington County lines. Several new lines connecting with the Maine Central are being built. The most remarkable of interior developments has been brought about by the Bangor and Aroostook railway opening up in the three north-eastern counties an area of over 4,000,000 acres—almost equal to that of the state of Massachusetts. These lands are fertile, well wooded and watered, with abundant water-power. Every available tract of timber on the line of this railway has been taken up for the purpose of some form of manufacture. Mills have been erected with an annual capacity of 125,000,000 feet of long lumber. Other wood products have been transported by this railway amounting to 226,000 tons a year. A pulp and paper mill is under construction, of an annual capacity of 120,000 tons. The soil in this region is well adapted to the raising of grain, in which there is accordingly a rapid increase. Five million bushels of potatoes go out to market each season, and fifty starch factories in Aroostook county consume three million bushels more. Every industry feels the stimulus of better facilities for moving products. This railway has already 325 miles in operation, and is pushing its branches wherever opportunities offer.

Trade, Domestic and Foreign.—Foreign trade is mostly for the foreign account, and is carried on in foreign ships. Much of this is for the Canada trade connected with the Grand Trunk railway. The value of the exports through the port of Portland for the year ending 30th June 1900 is seen in the following items: domestic, \$9,731,373; foreign (Canada), \$8,333,407; from frontier ports, \$14,708,285; a total of \$32,773,065. The value of the imports for the same period was: domestic consumption, \$782,863; in transit, \$8,254,064; a total of \$9,036,927, and grand total of business, \$41,809,992. The amount of duties assessed at this port was \$5,524,707, of which only \$98,297 was collected here, the balance being settled in other ports. The total amount of collections here, however, for the fiscal year 1900 from all sources was \$129,271, an increase over the same for the previous year of \$30,000. A very large amount of foreign business is done here which is without pecuniary benefit to the United States revenue, and which does not appear in any reports published by the Government.

Education.—The percentage of illiterates in this state is very low, and among the families of the original stock is almost inappreciable. Among the native-born adult males, 5671, out of a total of 178,931, or 3·2 per cent., were unable to write; while among the foreign-born, 8281, out of a total of 38,732, or 21·4 per cent., were unable to write. Out of all adult males, 6·4 per cent. were unable to write. The laws requiring school attendance for at least 16 weeks in each year of children under 15 years of age employed in factories are strictly enforced. The number of pupils in the public schools is about 200,000; the teachers number 6500; the annual school expenditure is \$1,600,000. There are four normal schools for the training of teachers, with a total average attendance of 485. Besides the high schools connected with the public school system, there are thirty-seven academies for secondary instruction, with a permanent investment of nearly \$50,000 and an average attendance of 2400. Great advance has been made in the means and methods of superior instruction. The leading colleges in the state are Bowdoin, Colby, Bates, and the University of Maine (College of Agriculture and Mechanic Arts). They have a total annual attendance of students averaging 1033, with 88 academic instructors,

and a total endowment of \$3,059,200. They are receiving generous gifts from friends, especially for libraries and laboratories. Not less than half a million dollars have lately been so given to Bowdoin. The Congregationalists have a theological seminary at Bangor, and the Free Baptists one at Lewiston. A law school has been established at Bangor connected with the University at Orono. The Maine Medical School, attached to Bowdoin College, is an institution of the first class. Free public libraries are rapidly extending through the towns.

Charitable Institutions.—Among institutions of a charitable or remedial nature are the Maine General Hospital at Portland, and similar establishments at Lewiston and Bangor; the Asylum for the Insane at Augusta, and another at Bangor; the Eye and Ear Infirmary, and School for the Deaf at Portland. Other institutions of similar general character are the Soldiers' Orphans' Home at Bath; the Industrial School for Girls at Hallowell; the Good Will Farm at Fairfield; and perhaps to be classed here, the Reform School for Boys at Portland, although this is in some aspects a penal institution. The National Home for Volunteer Soldiers at Togus and the Marine Hospital at Portland are institutions of the national Government.

Military.—There is an effective militia organization in the state, from which a volunteer regiment of infantry and four batteries of artillery—an aggregate of 1821 officers and men—were furnished for the Spanish war, in addition to detachments for the U.S. Volunteer Signal Service, Engineers, and Naval Reserve, and others for the regular army.

Liquor Laws.—The prohibitory liquor law, although supported by a recent constitutional amendment to a similar effect, labours under the disadvantage of all laws not vigorously sustained by general public sentiment. For the most part it is executed to the degree demanded by local sentiment in the several municipalities, thus operating in practice much the same as a "local option" law. This is not through default of moral sense among the people; it is simply a question of expediency as to what measures will best, with least attendant evil, restrain indulgence in intoxicating liquors. On this the judgment of fair-minded citizens is divided. The present law looks to checking the demand by preventing the supply; and since habitual reliance on the stringency of law tends to the neglect of other influences for the removal of evils from the community, the citizens seem to absolve themselves from personal responsibility both for the execution of the law and for the existence of the evil itself. At the same time, the existing law sets a standard of moral conduct for the community, which is supposed to express its best sentiment; and even though it fails fully to effect its immediate object, the people would probably be unwilling to repeal the legal and constitutional prohibition. (See LIQUOR LAWS.)

Religion.—The most prominent religious denominations are the Congregationalists, who have 250 churches and 21,600 members; the Baptists, with 249 churches and 20,051 members; the Methodists, 304 churches and 19,483 members; the Free Baptists, 240 churches and 13,703 members; and the Roman Catholics, who report 86 churches and a Catholic population of 96,400. Religious tendencies are towards practical rather than dogmatic questions—towards a liberalizing of the scholastic creeds and closer fellowship of all Christians. (J. L. C.)

Maine, Sir Henry James Sumner (1822–1888), the principal founder in Great Britain of the historical and comparative study of jurisprudence, was born on 15th August 1822. He was at school at Christ's Hospital, and thence went up to Pembroke College, Cambridge, in 1840. At Cambridge he was one of the most brilliant classical scholars of his time. Some of his Greek translations from English poetry are preserved in *Arundines Cami*. He took a Craven University scholarship and other prizes, and graduated as senior classic in 1844, being also senior Chancellor's medallist in classics. Shortly afterwards he accepted a tutorship at Trinity Hall. In 1847 he was appointed regius professor of civil law, and he was called to the Bar three years later; he held this chair till 1854. It will be remembered that even the rudiments of Roman law were not then included in the ordinary training of English lawyers; it was assumed at the universities that any good Latin scholar could qualify himself at short notice for keeping up such tradition of civilian studies as survived. Maine cannot have known much Roman law in 1847, but in 1856 he contributed to the *Cambridge Essays* the essay on Roman Law and Legal Education, republished

in the later editions of *Village Communities*, which was the first characteristic evidence of his genius. Meanwhile he had become one of the Readers appointed by the Inns of Court, in the first of their many half-hearted attempts at legal education, in 1852. Lectures delivered by Maine in this capacity were the groundwork of *Ancient Law*, published in 1861, the book by which his reputation was made at one stroke. Its object, as modestly stated in the preface, was "to indicate some of the earliest ideas of mankind, as they are reflected in Ancient Law, and to point out the relation of those ideas to modern thought." Within a year of its publication the post of Legal Member of Council in India was offered to Maine, then a junior member of the Bar with little practice, few advantages of connexion, and no political or official claims; in short, with none of the common qualifications. He declined once, on grounds of health; the very next year the office was again vacant. This time Maine was persuaded to accept, not that his health had improved, but that he thought India might not make it much worse. It turned out that India suited him much better than Cambridge or London. His work, like most of the work done by Englishmen in India in time of peace, was not of a showy kind; its value is shown by the fact that he was asked to prolong his services beyond the regular term of five years, and returned to England only in 1869. The subjects on which it was his duty to advise the Government of India were as much political as legal. They ranged from such problems as the land settlement of the Punjab, or the introduction of civil marriage to provide for the needs of unorthodox Hindus, to the question how far the study of Persian should be required or encouraged among European civil servants. On the civil marriage question in particular, and some years earlier on the still more troublesome one of allowing the remarriage of native converts to Christianity, his guidance, being not only learned but statesman-like, was of the greatest value. Plans of codification, moreover, were prepared, and largely shaped, under Maine's direction, which were carried into effect by his successors Fitzjames Stephen and Mr Whitley Stokes. The results are open to criticism in details, but form on the whole a remarkable achievement in the conversion of unwritten and highly technical law into a body of written law sufficiently clear to be administered by officers to many of whom its ideas and language are foreign. All this was in addition to the routine of legislative and consulting work, and the establishment of the legislative department of the Government of India on substantially its present footing.

Maine's power of swiftly assimilating new ideas and appreciating modes of thought and conduct remote from modern Western life came into contact with the facts of Indian society at exactly the right time, and his colleagues and other competent observers expressed the highest opinion of his work. In return Maine brought back from his Indian office a store of knowledge which enriched all his later writings, though he took India by name for his theme only once. This essay on India was his contribution to the composite work entitled *The Reign of Queen Victoria* (ed. T. H. Ward, London, 1887). Not having been separately published, it is perhaps the least known of Maine's writings; but its combination of just perception and large grasp with command of detail is not easily matched outside Bishop Stubbs's prefaces to some of the chronicles in the Rolls series. As vice-chancellor of the University of Calcutta Maine commented, with his usual pregnant ingenuity, on the results produced by the contact of Eastern and Western thought. Three of these addresses were published, wholly or in part, in the later editions of *Village Communities*; the substance of others

is understood to be embodied in the Cambridge Rede lecture of 1875, which is to be found in the same volume. The practical side of Maine's experience was not long lost to India; he became a member of the Secretary of State's council in 1871, and remained so for the rest of his life. In 1869 Maine was appointed to the chair of historical and comparative jurisprudence newly founded in the University of Oxford by Corpus Christi College. Residence at Oxford was not required, and altogether the election amounted to an invitation to the new professor to resume and continue in his own way the work he had begun in *Ancient Law*. During the next eight years he published the principal matters of his lectures in a carefully revised literary form: *Village Communities in the East and the West*, 1871; *Early History of Institutions*, 1875; *Early Law and Custom*, 1883. In all these works the phenomena of societies in an archaic stage, whether still capable of observation or surviving in a fragmentary manner among more modern surroundings or preserved in contemporary records, are brought into line, often with quite peculiar felicity, to establish and illustrate the normal process of development in legal and political ideas.

In 1877 the Mastership of Trinity Hall, Cambridge, where Maine had formerly been tutor, became vacant. There were two strong candidates whose claims were so nearly equal that it was difficult to elect either; the difficulty was solved by a unanimous invitation to Maine to accept the post. His acceptance entailed the resignation of the Oxford chair, though not continuous residence at Cambridge. Ten years later considerations of a somewhat similar kind led to his election to succeed Sir William Harcourt as Whewell professor of international law at Cambridge. His all too short performance in this office is represented by a posthumous volume which had not received his own final revision (*International Law*, 1888).

Meanwhile Maine had published in 1885 his one work of speculative politics, a volume of essays on *Popular Government*, designed to show that democracy is not in itself more stable than any other form of government, and that there is no necessary connexion between democracy and progress. The book was deliberately unpopular in tone; it excited much controversial comment and some serious and useful discussion.

In 1886 there appeared in the *Quarterly Review* (clxii. 181) an article on the posthumous work of J. F. M'Lennan, edited and completed by his brother, entitled "The Patriarchal Theory." The article, though necessarily unsigned, was Maine's reply to the M'Lennan brothers' attack on the historical reconstruction of the Indo-European family system put forward in *Ancient Law* and supplemented in *Early Law and Custom*. Maine was generally averse from controversy, but showed on this occasion that it was not for want of controversial power.

He carried the war back into the invader's country, and charged J. F. M'Lennan's theory of primitive society with owing its plausible appearance of universal validity to general neglect of the Indo-European evidence and misapprehension of such portions of it as M'Lennan did attempt to handle.

Maine's health, which had never been strong, gave way towards the end of 1887. He went to the Riviera under medical advice, and died at Cannes on 3rd February 1888. He left a wife and two sons, of whom the elder died soon afterwards.

An excellent summary of Maine's principal writings may be seen in Sir Mountstuart Grant Duff's memoir. The prompt and full recognition of Maine's genius by Continental publicists must not pass unmentioned even in the briefest notice. France, Germany, Italy, Russia have all contributed to do him honour; this is the more remarkable as one or two English publicists of an older school signally failed to appreciate him. Maine warned his countrymen against the insularity which results from ignorance of all law and institutions save one's own; his example has shown the benefit of the contrary habit. His prominent use of Roman law and the wide range of his observation have made his works as intelligible abroad as at home, and thereby much valuable information—for example, concerning the nature of British supremacy in India, and the position of native institutions there—has been made the property of the world of letters instead of the peculiar and obscure possession of a limited class of British public servants. Foreign readers of Maine have perhaps understood even better than English ones that he is not the propounder of a system but the pioneer of a method, and that detailed criticism, profitable as it may

SIR HENRY MAINE.

(From a photograph by Fredk. Hollyer of the painting by Lowes Dickinson.)

be and necessary as in time it must be, will not leave the method itself less valid or diminish the worth of the master's lessons in its use. The rather small bulk of Maine's published and avowed work may be accounted for partly by a fine literary sense which would let nothing go out under his name unfinished, partly by the drawbacks incident to precarious health. Maine's temperament was averse from the labour of minute criticism, and his avoidance of it was no less a matter of prudence. But it has to be remembered that Maine also wrote much which was never publicly acknowledged. Before he went to India he was one of the original contributors to the *Saturday Review*, founded in 1855, and the inventor of its name. Like his intimate friend Fitzjames Stephen, he was an accomplished journalist, enjoyed occasional article-writing as a diversion from official duties, and never quite abandoned it. The practice of such writing probably counted for something in the freedom and clearness of Maine's style and the effectiveness of his dialectic. His books are a model of scientific exposition which never ceases to be literature.

Maine-et-Loire, a department of the west of France, watered by the Loire and its affluent the Maine, which is itself formed by the confluence of the Mayenne and the Sarthe.

Area, 2812 square miles. From 527,680 in 1886 the population decreased to 513,208 in 1901. The births in 1899 numbered 9404, of which 595 were illegitimate; deaths, 10,054; marriages, 3843. There were in 1896, 979 primary schools, with 62,000 pupils, the illiterate constituting 5 per cent. of the population. The area under cultivation amounted (1896) to 1,624,193 acres, of which 1,132,738 acres were plough-land and 99,323 acres vineyards. Of considerable agricultural wealth, the department in 1899 produced wheat valued at £1,718,000; barley, £104,000; oats, £312,000; vines, £600,000; potatoes, £340,000; mangold-wurzel, £132,000; hemp, in harl and in seed, £56,000; flax, in harl and in seed, £34,000; walnuts, £16,000. The live stock included (1899) 63,620 horses, 277,220 cattle, 59,250 sheep, and 100,000 pigs. Mining in 1898 produced 14,600 tons of coal, but there is no industry in metals. The slate quarries of Angers are noted for their abundance and quality. The manufacture of hempen and other textile stuffs is in an advanced state. Angers, the capital, in 1901 had 82,966 inhabitants.

Mainpuri, a town and district of British India, in the Agra division of the North-West Provinces. The town is on the Agra branch of the Grand Trunk road, 36 miles from the station of Shikohabad. Population (1881), 20,236; (1891), 18,551. Registered death-rate (1897), 41·8 per thousand. The municipal income in 1897-98 was Rs.16,580, the incidence of taxation being 12 annas per head. It has a speciality of wooden articles inlaid with wire. The American Presbyterian mission manages a high school.

The district of **MAINPURI** lies in the central Doab. Area, 1701 square miles; population (1881), 801,216; (1891), 762,163; (1901), 829,350, showing a decrease of 5 per cent. between 1881 and 1891, and an increase of 8·8 between 1891 and 1901; average density, 487 persons per square mile. The land revenue and rates are Rs.14,86,835, the incidence of assessment being R.1.2.4 per acre; cultivated area (1896-97), 491,779 acres, of which 395,831 were irrigated from wells, &c., including 176,754 from Government canals; number of police, 2392; number of vernacular schools (1896-97), 121, with 3744 pupils. The registered death-rate in 1897 was 36 per thousand. The district is watered by two branches of the Ganges canal, and is traversed for 23 miles by the main line of the East Indian railway, with two stations. Indigo is an important crop, grown on 35,000 acres, with an out-turn valued at Rs.4,71,000.

Mainz, in French *Mayence*, a first-class fortress, river port, and bishop's see of Germany, grand-duchy of Hesse-Darmstadt, on the left bank of the Rhine (*q.v.*), almost directly opposite the influx of the Main, though the fortress, manned by a garrison of 8000 men, belongs to the empire. Since the defensive works were pushed back in 1871, a new quarter of straight wide streets, intersecting at right angles, has been built on the north of the old town, room being also found for two spacious harbours, completed in 1887 at a cost of a quarter of a million sterling. The river front has been converted into a fine promenade, over 300 feet wide, and planted with trees. From the middle of it an equally wide and handsome street, the Kaiserstrasse, goes from the Rhine to the new central railway station (1884), and at the same time separates the new town from the old town. In 1881-85 a new bridge of five arches (the centre arch with a span of 335 feet) was thrown across the Rhine to the opposite suburb of Kastel. The concert hall (a handsome Renaissance building) on the Rhine promenade, the concert hall (1890) of the Mainz Musical Society, the new classical

school (gymnasium), the imperial bank (1894), and the offices of the Hesse-Ludwig Railway Company, and Christ Church (1899-1900) are the more noteworthy of modern public buildings. Of the older, the church of St Stephen's (1257-1328; restored in 1857) and St Emmeran's (restored in 1881) should be mentioned. Mainz has theological seminaries and an industrial art school. There is a very considerable trade, by river and rail, principally in wine, cereals and flour, timber, petroleum, paper, iron and steel, and vegetables. The industries are chiefly concerned with the production of artistic furniture and leather goods, carriages, vegetables (asparagus, &c.), preserved foods for the army, tobacco, boots, pianos, varnishes, books, &c. Population (1885), 65,852; (1900), 84,335.

Maitland, East and West, adjoining municipalities, in New South Wales, Australia, in the county of Northumberland, 120 miles north of Sydney by rail, on the Hunter river about 4 miles above the limit of navigation for steamers. They are the centre of the agricultural district of the Hunter valley. Public buildings include a large town hall (1890), court-house, and new masonic hall. West Maitland is protected from floods by stone embankments built at a cost of £30,000, and flood-gates costing £12,000 have been erected on Wallis Creek at East Maitland. Population of West Maitland (1881), 5703; (1901), 6798; of East Maitland (1881), 2302; (1901), 3287.

Majorca, or MALLORCA. See BALEARIC ISLANDS.

Makart, Hans (1840-1884). See SCHOOLS OF PAINTING (*Austria*).

Malabar, a district of British India, in the Madras presidency. Geographically the name is sometimes extended to the entire western coast of the peninsula. Properly it should apply to the strip below the Ghats, which is inhabited by people speaking the Malayalam language, a branch of the Dravidian stock, who form a peculiar race, with castes, customs, and traditions of their own. It would thus be coextensive with the old kingdom of Chera, including the modern states of Travancore and Cochin, and part of Kanara. In 1891 the total number of persons speaking Malayalam was 5,428,250.

The district of **MALABAR** extends for 145 miles along the coast, running inland to the Ghats for a breadth varying from 70 to 25 miles. The administrative headquarters are at Calicut. Area, 5585 square miles; population (1881), 2,365,035; (1891), 2,652,565; (1901), 2,788,043, showing an increase of 12 per cent. between 1881 and 1891, and of 5·1 per cent. between 1891 and 1901; average density, 499 persons per square mile, being the second highest in the province. The land revenue and rates in 1897-98 were Rs.23,41,854, the incidence of assessment being Rs.2.2.9 per acre; cultivated area, 959,239 acres, of which 39,344 were irrigated from tanks, &c.; number of police, 1463; boys at school (1896-97), 66,274, being 33·6 of the male population of school-going age; girls at school, 18,499, being 9·2 per cent.; registered death-rate (1897), 30·2 per thousand, the mortality from cholera alone having been 10·4 per thousand. The one staple crop is rice, the next most important product being cocoa-nuts. Coffee is grown on 17,872 acres, chiefly in the upland track known as the Wainad, where also there are 855 acres under tea. The chief means of communication is by the backwaters or lagoons, which form almost a complete chain along the coast. The Madras railway crosses the district for 90 miles, and is being extended from Calicut to Cannanore (62 miles). There are 11 seaports, of which the principal are Calicut, Tellicherry, Cannanore, and Cochin. In 1897-98 the sea-borne trade was valued at Rs.6,27,14,875, the principal exports being coffee, cocoa-nut products, and timber. There are factories for cleaning coffee, pressing coir and making matting, making tiles, sawing timber, and weaving cotton.

Malacca, a town situated on the west coast of the Malay Peninsula, in 2° 14' N. and 102° 12' E., which gives its name to the strait dividing the island of Sumatra from the mainland. Its name, which is more correctly transliterated *Mēlāka*, means a species of jungle fruit,

and is also borne by a river on the right bank of which the old Dutch town stands, being connected by a bridge with the business quarter on the left bank, which is inhabited almost exclusively by Chinese, Eurasians, and Malays.

Malacca, now a somnolent little town, visited by few ships, and holding the least important position of all the three settlements in that strait, has a remarkable history. An account of it given in 1503 by a Roman youth, Ludovigo Barthema, called Vertomannus in Eden's translation of 1576, shows that even at that time Malacca was one of the most important centres of trade in the East. Its Malay sultan was perhaps the most considerable chief of his race, and was certainly more powerful than any other ruler then living in the Peninsula. Malacca is also one of the oldest European settlements in eastern Asia, it having been wrested from Sultan Muhammad Shah by Albuquerque in 1511, in punishment for an attack made in 1509 on his lieutenant Sequeira. It was held by the Portuguese until 1641, when the Dutch, with the help of the Achinese, succeeded in capturing the citadel, several attempts to take it having previously been made without success. It was under the Portuguese Government that St Francis Xavier started a mission in Malacca, the first Christian mission to Malayan lands. The Dutch held Malacca until 25th August 1795, when it was taken from them by a British expedition, and the Dutch Government was dissolved on 4th December of the same year. The British administration under Admiral Mainwaring abolished the system of monopoly in the Straits, as Raffles did afterwards throughout Malaya in 1813. In 1818 Malacca was restored to the Dutch under the Treaty of Vienna, but in 1824 it came finally into the hands of Great Britain, being exchanged by a treaty with Holland for the East India Company's settlement of Bencoolen and a few other unimportant places on the western coast of Sumatra. By this treaty the Dutch were precluded from interference in the affairs of the Malay Peninsula, and Great Britain from similar action in regard to the states of Sumatra, with the sole exception of Acheen, the right to protect which state was not abandoned by Great Britain until 1872 by the treaty concluded with Holland in that year. It was not until 1833 that the whole territory lying to the back of Malacca was finally brought under British control, and as late as 1887 the Nègri Sāmbilan, or Nine States, which adjoin Malacca territory on the east and north-east, were completely independent. They now, with the state of Sūngei Ujong, form part of the Federated Malay States under British protection. Malacca is administered by a resident councillor, who is responsible to the governor of the Straits Settlements, and by a number of district officers and other officials under his direction. The population of the town and territory of Malacca in 1901 was 95,487, of whom only 74 were Europeans and Americans, 1598 were Eurasians, the rest being Asiatics (chiefly Malays, with a considerable sprinkling of Chinese). The population in 1891 was 92,170. The birth-rate in 1898 was 35 per thousand, the death-rate 28.97. The revenue for 1898 amounted to \$376,335, and the expenditure to \$393,411. In 1900 the imports totalled \$2,322,036, and the exports \$2,787,128. During 1898, 1503 ships, with an aggregate tonnage of 306,580, entered the port of Malacca; this will serve to show how completely the trade of this once flourishing port has declined, most of the vessels being merely coasting craft, and no large line of steamers holding any communication with the place. This is accounted for partly by the shallowness of the harbour, and partly by the fact that the ports of Penang and Singapore, at either entrance to the Strait of Malacca, draw all the trade and shipping to themselves. Malacca is chiefly remarkable for the number of wealthy retired Chinese merchants who resort thither to pass the years of their old age in preference to returning to China, where they would become a prey to the avarice of Chinese officials.

(H. CL.)

Malacostraca.—Under the zoological title Malacostraca are included several groups of Crustacea (*q.v.*), united by characters which attest their common origin, though some, and probably all of them, were already separated in distant geological ages, and some have now attained a peculiar isolation. Throughout the whole, the researches made since 1860 have not only added a great throng of new species, genera, and families, but have thrown a flood of light upon questions of their phylogeny, systematic arrangement, horizontal and bathymetric distribution, organization, habits of life, and economic importance. There are at least seven

orders: the stalk-eyed Brachyura, Macrura, Schizopoda, Stomatopoda, and the sessile-eyed Sympoda, Isopoda, Amphipoda. An ocular segment claimed by the former division is not present or in no case demonstrable in the latter. In neither does the terminal segment or telson, whether large or obsolescent, whether articulated or coalescent, carry appendages, unless occasionally in fusion with itself. Between the eyes and the tail-piece in all the orders nineteen segments are counted, the proof of a segment's existence depending on its separateness, complete or partial, or on a sutural indication, or else on the pair of appendages known to belong to it. All these marks may fail, and then the species must be proved to be Malacostracan by other evidence than the number of its segments; but if some exceptions exhibit fewer, none of the Malacostraca exhibit more than 19 (+1 or +2) segments, unless the Nebaliidæ be included. Of the corresponding pairs of appendages thirteen belong to the head and trunk, two pairs of antennæ, one pair of mandibles, two pairs of maxillæ, followed by three which may be all maxillipeds or may help to swell the number of trunk-legs to which the next five pairs belong. The abdomen or pleon carries the remaining six pairs, of which from three to five are called pleopods and the remainder uropods. Underlying the diversity of names and functions and countless varieties of shape, there is a common standard to which the appendages in general can be referred. In the maxillipeds and the trunk-legs it is common to find or otherwise easy to trace a seven-jointed stem, the endopod, from which may spring two branches, the epipod from the first joint, the exopod from the second.¹ The first antennæ are exceptional in branching, if at all, at the third joint. In the mandibles and maxillæ some of the terminal joints of the stem are invariably wanting. In the rest of the appendages they may either be wanting or indistinguishable. The latter obscurity results either from coalescence, to which all joints and segments are liable, or from subdivision, which occasionally affects joints even in the trunk-legs. The carapace, formerly referred only to the antennar-mandibular segments, may perhaps in fact contain elements from any number of other segments of head and trunk, Huxley, Alcock, Bouvier giving support to this opinion by the sutural or other divisional lines in *Potamobius*, *Nephrops*, *Thalassina*, and various fossil genera. Not all questions of classification internal to this division are yet finally settled. Between the Brachyura and Macrura some authors uphold an order Anomura, though in a much restricted sense, the labours of Huxley, Boas, Alcock, and conjointly Alphonse Milne-Edwards and Bouvier, having resulted in restoring the Dromiidea and Raninidæ to the Brachyura, among which de Haan long ago placed them. The French authors argue that from the macruran lobsters (*Nephropsidæ*) anciently diverged two lines, one leading through the Dromiidea to the genuine Brachyura or crabs, the other independently to the Anomura proper, which may conveniently be named and classed as *Macrura anomala*. Spence Bate maintained that the Schizopoda ought not to form a separate order but to be graded as a macruran tribe, "more nearly allied to the degraded forms of the Penæidea than to those of any other group" ("*Challenger*" Reports, "Macrura," p. 472, 1888). According to Sars, the Sympoda (or Cumaceans), in spite of their sessile eyes, have closer affinities with the stalk-eyed orders. H. J. Hansen and others form a distinct order Tanaidea for the decidedly anomalous group called by Sars *Isopoda chelifera*.

BRACHYURA.—For the present, as of old, the true Brachyura are divided into four tribes:—*Cyclometopa*, with arched front as

¹ In Huxley's terminology the first two or three joints of the stem constitute a "protopodite," from which spring the "endopodite" and "exopodite."

in the common eatable crab; *Catometopa*, with front bent down as in the land-crabs and the little oyster-crab; *Oxyrhyncha*, with sharpened beak-like front as in the various spider-crabs; *Oxystomata*, including the Raninidae, and named not from the character of the front but from that of the buccal frame which is usually narrowed forwards. In these tribes the bold and active habits, the striking colours, or the fantastic diversities of structure, have so long attracted remark that recent investigations, while adding a multitude of new species and supplying the specialist with an infinity of new details, have not materially altered the scientific standpoint. New light, however, has been thrown upon the "intellectual" capacity of Crustacea by the proof that the spider-crabs deliberately use changes of raiment to harmonize with their surroundings, donning and doffing various natural objects as we do our manufactured clothes. Others have the power of producing sounds, one use to which they put this faculty being apparently to signal from their burrow in the sand that they are "not at home" to an inopportune visitor. Deep-sea exploration has shown that some species have an immensely extended range, and still more, that species of the same genus and genera of the same family, though separated by great intervals of space, may be closely allied in character. A curious effect of parasitism, well illustrated in crabs, though not confined to them, has been expounded by Professor Giard, namely, that it tends to obliterate the secondary sexual characters. Modern research has discovered no crab to surpass *Macrocheira kämpferi*, de Haan, that can span between three and four yards with the tips of its toes, but at the other end of the scale it has yielded *Collodes malabaricus*, Alcock, "of which the carapace, in an adult and egg-laden female, is less than one-sixth of an inch in its greatest diameter." The most abyssal of all crabs yet known is *Ethusia abyssicola*, Smith, or what is perhaps only a variety of it, *E. challengerii*, Miers. Of the latter the *Albatross* obtained a specimen from a depth of 2232 fathoms (Faxon, 1895), of the former from 2221 fathoms, and of this S. I. Smith remarks that it has "distinctly faceted black eyes," although in them "there are only a very few visual elements at the tips of the immobile eye-stalks."

The *Brachyura anomala* or Dromiidea "have preserved the external characters and probably also the organization of the Brachyura of the Secondary epoch" (Milne-Edwards and Bouvier, 1901). They agree with the true crabs in not having appendages (uropods) to the sixth segment of the pleon, the atrophy being complete in the Homolidae and Homolodromiidae, whereas in the Dromiidae and Dynomenidae a pair of small plates appear to be vestiges of these organs. In the family Homolidae stands the strange genus *Latreillia* (Roux), with long slender limbs and triangular carapace after the fashion of oxyrhynch spider-crabs. In *Homola* the carapace is quadrilateral. Between these two a very interesting link was discovered by the *Challenger* in the species *Latreillopsis bispinosa*, Henderson. Bouvier (1896) has shown that *Palaeinachus longipes*, Woodward, from the Forest Marble of Wiltshire, is in close relationship, not to the oxyrhynch Inachidae, but to the genera *Homolodromia* and *Discranodromia* of the Homolodromiidae, and that the Jurassic crabs in general, of the family Prosonopidae (Meyer), are Dromiidea.

2. MACRURA.—The *Macrura anomala*, or Anomura in restricted sense, are popularly known through the hermit-crabs alone. These only partially represent one of the three main divisions Paguridea, Galatheidea, Hippidea. The first of these is subdivided into *Pagurinea*, *Lithodinea*, *Lomisinea*, each with a literature of its own. Among the *Pagurinea* is the *Birgus latro* or robber-crab, whose expertness in climbing the cocoanut palm need no longer be doubted, since in recent years it has been noted and photographed by trustworthy naturalists in the very act. Alcock "observed one of these crabs drinking from a runnel of rain-water, by dipping the fingers of one of its chelipeds into the water and then carrying the wet fingers to its mouth." Hermits of the genus *Cenobita* he found feeding voraciously on nestling sea-terns. That pagurids must have the usually soft pleon or abdomen protected by the shell of a mollusc is now known to be subject to a multitude of exceptions. *Birgus* dispenses with a covering; *Cenobita* can make shift with half the shell of a cocoanut; *Chlænopagurus* wraps itself up in a blanket of colonial polyps; *Cancellus tanneri*, Faxon, was found in a piece of dead coral rock; *Xylopagurus reclusi*, A. Milne-Edwards, lodges in tubes of timber or bits of hollow reed. The last-named species has a straight symmetrical abdomen, with the penultimate segment expanded and strongly calcified to form a back-door to the very unconventional habitation. This it enters head-foremost from the rear, while "hermits" in general are forced to go backwards into their spiral or tapering shelters by the front. Some of the species can live in the ocean at a depth of two or three miles. Some can range inland up to a considerable height on mountains. The advantage that this group has derived from the adoption of mollusc shells as houses or fortresses, ready-built and light enough for easy transport, is obviously discounted by a twofold inconvenience. There is nothing to ensure that the supply will

be equal to the demand, and Nature has not arranged that the borrowed tenement shall continue to grow with the growth of its new tenant. To meet these defects it is found that numerous species encourage or demand the companionship of various zoophytes, simple or colonial. These sometimes completely absorb the shell on which they are settled, but then act as a substitute for it, and in any case by their outgrowth they extend the limits of the dwelling, so that the inmate can grow in comfort without having to hunt or fight for

FIG. 1.—*Neolithodes grimaldii*, A. Milne-Edwards and Bouvier.

a larger abode. Among the *Lithodinea* or stone-crabs, besides important readjustments of classification (Bouvier, 1895, 1896), should be noticed the evidence of their cosmopolitan range, and the species *Neolithodes agassizii* (Smith) and *N. grimaldii*, Milne-Edwards and Bouvier, which carry to an extreme the spinosity characteristic of the group (Fig. 1). S. I. Smith's investigations on the early stages of *Hippa talpoida*, Say, were published in 1877.

With regard to the accessions to knowledge in the enormous group of the genuine Macrura, reference need only be made to the extensive reports in which Spence Bate, S. I. Smith, Faxon, Wood-Mason, Alcock, and others have made known the results of celebrated explorations. Various larval stages have been successfully investigated by Sars. Alcock (1901) describes from his own observation the newly hatched *Phyllosoma* larva of *Thenus orientalis* (Fabricius). An admirable discrimination of the larval and adult characters of the genus *Sergestes* has been given by H. J. Hansen (*Proc. Zool. Soc.*, London, 1896). Singularity excites our wonder in *Thaumastocheles zaleucus* (v. Willemoes Suhm), which makes up for its vanished eyes by its extraordinary elongate and dentated claws; in *Psalidopus huxleyi*, Wood-Mason and Alcock (1892), bristling with spikes from head to tail; in the *Nematocarinidae*, with their long thread-like limbs and longer antennæ; in species of *Aristaeopsis* reported by Chun from deep water off the east coast of Africa, bright red prawns nearly a foot long, with antennæ about five times the length of the body. That certain species, particularly many from deep water, have disproportionately large eggs, is explained by the supposition that the young derive the advantage of being hatched in an advanced stage of development.

3. SCHIZOPODA.—This order of animals, for the most part delicately beautiful, has for the moment five families—Lophogastridae, Eucopiidae, Euphausiidae, Mysidae, and Anaspididae. In the Euphausiidae the digitiform-arborescent branchiæ, as if conscious of their own extreme elegance, remain wholly uncovered. In the two preceding families they are partially covered. In the Mysidae the branchiæ are wanting, and some would form this family into a separate order, Mysidacea. In *Anaspides*, a peculiar fresh-water genus discovered in 1892 by G. M. Thomson on Mount Wellington, in Tasmania, the gills are not arborescent, and there are seven segments of the trunk free of the carapace (Fig. 2). A membranaceous carapace separates the Eucopiidae from the more solidly invested Lophogastridae. Among many papers that the student will find it necessary to consult may be mentioned the

FIG. 2.—*Anaspides tasmaniae*, Thomson.

"Challenger" Report on Schizopoda, by Sars, 1885, dealing with the order at large; "British Schizopoda," by Norman, *Ann. Nat. Hist.*, 1892; "Decapoden und Schizopoden," *Plankton-Expedition*, Ortmann, 1893; "Euphausiidae," by Stebbing, *Proc. Zool. Soc.*, London, 1900; *Mysidæ of the Russian Empire*, by Czerniavski, 1882-83; and *Mysidæ of the Caspian*, by Sars, 1893-95-97.

4. STOMATOPODA.—This order, at one time a medley of heterogeneous forms, is now confined to the singularly compact group of the Squillidæ. Here the articulation of the ocular segment is unusually distinct, and here two characters quite foreign to all the preceding groups come into view. The second maxillipeds are developed into powerful prehensile organs, and the branchiæ, instead of being connected with the appendages of head and trunk, are developed on the pleopods, appendages of the abdomen. At least three segments of the trunk are left uncovered by the carapace. The developing eggs are not carried about by the mother, but deposited in her subaqueous burrow, "where they are aerated by the currents of water produced by the abdominal feet of the parent." An excellent synopsis of the genera and species is provided by R. P. Bigelow (*Proc. U.S. Mus.* vol. xvii., 1894). For the habits and peculiarities of these and many other Crustaceans, Verriill and Smith on the *Invertebrates of Vineyard Sound* should be consulted (1874). The general subject has been illuminated by the labours of Claus, Miers, Brooks ("Challenger" Report, 1886), and the latest word on the relationship between the various larvæ and their respective genera has been spoken by H. J. Hansen (*Plankton-Expedition Report*, 1895). The striking forms of *Alima* and *Erichthus*, at one time regarded as distinct genera, are now with more or less certainty affiliated to their several squillid parents.

5. SYMPODA.—This order of sessile-eyed decapods was absolutely unknown to science till 1779. A species certainly belonging to it was described by Lepekhin in 1780, but the obscure *Gammarus esca*, "food Gammarus" beloved of herrings, described by J. C. Fabricius in the preceding year, may also be one of its members. Nutritious possibilities are implied in *Diastylis rathkii* (Krøyer), one of the largest forms, which, though slender and rarely an inch long, in its favourite Arctic waters is found "in incalculable masses, in thousands of specimens" (Stuxberg, 1880). Far on in the 19th century eminent naturalists were still debating whether in this group there were eyes or no eyes, whether the eyes were stalked or sessile, whether the animals observed were larval or adult. The American Say in 1818 gave a good description of a new species and founded the premier genus *Diastylis*, but other investigators derived little credit from the subject till more than sixty years after its introduction by the Russian Lepekhin. Then Goodsir, Krøyer, Lilljeborg, Spence Bate, and one or two others made considerable advances, and in 1865 a memorable paper by G. O. Sars led the way to the great series of researches which he has continued to the present day. The name *Cumacea*, however, which he uses cannot be retained, being founded on the preoccupied name *Cuma* (Milne-Edwards, 1828). The more recent name *Sympoda* (see Willey, *Results*, part v. p. 609, 1900) alludes to the huddling together of the legs, which is conspicuous in the species. Ten families are now distinguished—*Diastylidæ*, *Lampropidæ*, *Platyaspidæ*, *Pseudocumidæ*, all with an articulated telson; without one, the *Bodotriidæ* (formerly called *Cumidæ*), *Vaunthomsoniidæ*, *Leuconidæ*, *Nannastacidæ*, *Campylaspidæ*, *Procampylaspidæ*. All the *Leuconidæ* and *Procampylaspidæ* are blind, and some species in most of the other families. Usually the sides of the carapace are strangely produced into a mock rostrum in front of the ocular lobe, be it oculiferous or not. The last four or five segments of the trunk are free from the carapace. The slender pleon has always six distinct segments, the sixth carrying two-branched uropods, the preceding five armed with no pleopods in the female, whereas in the male the number of pairs varies from five to none. The resemblance of these creatures to miniature *Macrura* is alluded to in the generic name *Nannastacus*, meaning dwarf-lobster. In this genus alone of the known *Sympoda* the eyes sometimes form a pair, in accordance with the custom of all other malacostracan orders except this and of this order itself in the embryo (Sars, 1900). The most but not the only remarkable character lies in the first maxillipeds. These, with the main stem more or less pediform, have the epipod and exopod modified for respiratory purposes. The backward-directed epipods usually carry branchial vesicles. The forward-directed exopods either act as valves or form a tube (rarely two tubes), protensile and retractile, for regulating egress of water from the branchial regions. This mechanism as a whole is unique, although, as Sars observes, the epipod of the first maxillipeds has a respiratory function also in the *Lophogastridæ* and *Mysidæ* and in the cheliferous isopods. As a rule armature of the carapace is much more developed in the comparatively sedentary female than in the usually more active male. Only in the male do the second antennæ attain considerable length, with strong resemblance to what is found in some of the Amphipoda. About 150 species distributed among thirty-four genera

are now known, many from shallow water and from between tide-marks, some from very great depths. H. J. Hansen concludes that "they are all typically ground animals, and as yet no species has been taken under such conditions that it could be reckoned to the pelagic plankton." As they have been found in all zones and chiefly by a very few observers, it is probable that a great many more species remain to be discovered. In recent years thirteen species, all belonging to the same genus *Pseudocuma* (Fig. 3), have

FIG. 3.—*Pseudocuma Pectinatum*, Sowinsky.

been recorded by Sars from the Caspian Sea. A bibliography of the order is given in that author's *Crustacea of Norway*, vol. iii., 1899-1900.

6. ISOPODA.—This vast and populous order can be traced far back in geological time. It is now represented in all seas and lands, in fresh-water lakes and streams, and even in warm springs. It adapts itself to parasitic life not only in fishes, but in its own class Crustacea, and that in species of every order, its own included. In this process changes of structure are apt to occur, and sometimes unimaginable sacrifices of the normal appearance. The order has been divided into seven tribes, of which a fuller summary than can here be given will be found in Stebbing, *History of Crustacea*, 1893. The first tribe, called Chelifera, from the usually chelate or claw-bearing first limbs, may be regarded as *Isopoda anomala*, of which some authors would form a separate order, Tanaidea. Like the genuine isopods, they have seven pairs of trunk-legs, but instead of having seven segments of the middle body (or pereon) normally free, they have the first one or two of its segments coalesced with the head. Instead of the breathing organs being furnished by the appendages of the pleon with the heart in their vicinity, the respiration is controlled by the maxillipeds, with the heart in the pereon (see Delage, *Arch. Zool. expér. et gén.* vol. ix., 1881). There are two families, Tanaidæ and Apeudidæ. Occasionally the ocular lobes are articulated.

The genuine Isopoda are divided among the *Flabellifera*, in which the terminal segment and uropods form a flabellum or swimming fan; the *Epicaridea*, parasitic on Crustaceans; the *Valvifera*, in which the uropods fold valve-like over the branchial pleopods; the *Asellota*, in which the first pair of pleopods of the female are usually transformed into a single opercular plate; the *Phreatoidea*, a fresh-water tribe, known as yet only from subterranean waters in New Zealand and an Australian swamp nearly 6000 feet above sea-level; and lastly, the *Oniscidea*, which are terrestrial. Only the last of these, under the contemptuous designation of wood-lice, has established a feeble claim to popular recognition. Few persons hear without surprise that England itself possesses more than a score of species in this air-breathing tribe. Those known from the world at large number hundreds of species, distributed among dozens of genera in six families. That a wood-louse and a land-crab are alike Malacostracans, and that they have by different paths alike become adapted to terrestrial life, are facts which even a philosopher might condescend to notice. Of the other tribes which are aquatic there is not space to give even the barest outline. Their swarming multitudes are of enormous importance in the economy of the sea. If in their relation to fish it must be admitted that many of them plague the living and devour the dead, in return the fish feed rapaciously upon them. Among the most curious of recent discoveries is that relating to some of the parasitic *Cymothoidæ*, as to which Bullar has shown that the same individual can be developed first as a male and then as a female. Of lately-discovered species the most striking is one of the deep-sea *Cirolanidæ*, *Bathynomus giganteus*, A. M. Edwards, 1879, which is unique in having supplementary ramified branchiæ developed at the bases of the pleopods. Its eyes are said to contain nearly 4000 facets. The animal attains what in this order is the monstrous size of 9 inches by 4. A general uniformity of the trunk-limbs in Isopoda justifies the ordinal name, but the valviferous *Astacillidæ*, and among the *Asellota* the *Munnopsidæ*, offer some remarkable exceptions to this characteristic. Among many essential works on this group may be named the *Monogr. Cymothoarum* of Schiödte and Meinert, 1879-1883; "Challenger" Report, Bédard, 1884-86; *Cirolanidæ*, H. J. Hansen, 1890; *Isopoda Terrestria*, Budde-Lund, 1885; *Bopyridæ*, Bonnier, 1900; *Crustacea of Norway*, vol. ii. (Isopoda), Sars, 1896-99, while their multitude precludes specification of important contributions by Benedict, Bovallius, Chilton, Dohrn, Dollfus, Fraisse, Giard and Bonnier, Harger, Haswell, Kossmann,

Miers, M^cMurrich, Norman, Harriet Richardson, Ohlin, Studer, G. M. Thomson, A. O. Walker, Max Weber, and many others.

7. AMPHIPODA.—As in the genuine Isopoda, the eyes of Amphipoda are always sessile, and generally paired, and, in contrast to crabs and lobsters, these two groups have only four pairs of mouth-organs instead of six, but seven pairs of trunk-legs instead of five. From the above-named isopods the present order is strongly differentiated by having heart and breathing organs not in the pleon, but in the peræon, or middle body, the more or less simple branchial vesicles being attached to some or all of the last six pairs of trunk-legs. Normally the pleon carries six pairs of two-branched appendages, of which the first three are much articulated flexible swimming feet, the last three few-jointed comparatively indurated uropods. There are three tribes, *Gammaridea*, *Caprelliidea*, *Hyperiidea*. The middle one contains but two families, the cylindrical and often thread-like skeleton shrimps, *Caprelliidae*, and their near cousins, the broad, flattened, so-called whale-lice, *Cyamidae*. This tribe has the pleon dwindled into insignificance, whereas in the other two tribes it is powerfully developed. The *Hyperiidea* are distinguished by having their maxillipeds never more than three-jointed. In the companion tribes these appendages have normally seven joints, and always more than three. The order thus sharply divided is united by an intimate interlacing of characters, and forms a compact whole at present defying intrusion from any other crustacean group. Since 1775, when J. C. Fabricius instituted the genus *Gammarus* for five species, of which only three were amphipods, while he left five other amphipods in the genus *Oniscus*, from this total of eight science has developed the order, at first very slowly, but of late by great leaps and bounds, so that now the *Gammaridea* alone comprise more than 1300 species, distributed among some 300 genera and 39 families. They burrow in the sands of every shore; they throng the weeds between tide-marks; they ascend all streams; they are found in deep wells, in caverns, in lakes; in Arctic waters they swarm in numbers beyond computation; they find lodgings on crabs, on turtles, on weed-grown buoys; they descend into depths of the ocean down to hundreds or thousands of fathoms; they are found in mountain streams as far above sea-level as some of their congeners live below it. The *Talitridæ*, better known as sandhoppers, can forego the briny shore and content themselves with the damp foliage of inland forests or casual humidity in the crater of an extinct volcano. Over the ocean surface, as well as at various depths, float and swim innumerable *Hyperiidea*—the wonderful *Phronima*, glass-like in its glassy barrel hollowed out of some Tunicate; the *Cystisoma*, 4 or 5 inches long, with its eye-covered head; the *Rhabdosoma*, like a thin rod of glass, with needle-like head and tail, large eyes, but limbs and mouth-organs all in miniature, and the second antennæ of the male folding up like a carpenter's rule (Fig. 4).

FIG. 4.—*Rhabdosoma Piratum*, Stebbing.

On jelly-fishes are to be found species of *Hyperia* and their kindred, so fat and wholesome that they have been commended to shipwrecked men in open boats as an easily procurable resource against starvation. Many of the amphipoda are extremely voracious. Some of them are even cannibals. The *Cyamidae* afflict the giant whale by nibbling away its skin; the *Chelura terebrans* is destructive to submerged timber. But, on the other hand, they largely help to clear the sea and other waters of refuse and carrion, and for fishes, seals, and whales they are food desirable and often astoundingly copious. From the little flea-like species, scarcely a tenth of an inch long, up to the great and rare but cosmopolitan *Eurythenes gryllus* (Lichtenstein), and the still larger *Alicella gigantea*, Chevreux, nearly half a foot long, captured by the prince of Monaco from a depth of 2936 fathoms, not one of these ubiquitous, uncountable hordes has ever been accused of assailing man. For the naturalist they have the recommendation that many are easy to obtain, that most, apart from the very minute,

are easy to handle, and that all, except as to the fleeting colours, are easy to preserve. A nearly complete bibliography of the order down to 1888 will be found in the "*Challenger*" Reports, vol. xxviii., and supplementary notices in della Valle's *Monograph of the Gammarini*, 1893, the scope of his work, however, not covering the *Hyperiidea* and *Oxycephalidæ* of Bovallius, 1889, 1890; but since these dates very numerous additions to the literature have been made by Birula, Bonnier, Norman, Walker, and others, especially the *Crustacea of Norway*, vol. i. (*Amphipoda*), Sars, 1890-95, demanding attention, and the quite recent *Amphipoda of the Hirondele*, Chevreux, 1900, and *Hyperiidea of the Plankton-Expedition*, Vosseler, 1901.

(T. R. R. S.)

Malaga, a maritime province of southern Spain. It has an area of 2823 miles, and had a population of 519,977 in 1887 and 490,331 in 1897. It is divided into 14 administrative districts and 103 parishes. The birth-rate is 3.95 per cent., the death-rate 3.49 per cent., and the proportion of illegitimate births 3.42 per cent. The decrease in population was due to emigration to Brazil, the Argentine, and French Algeria. Communication by state, provincial, and municipal roads has been somewhat improved since 1890, but only very slightly. There are only 50 miles of first-class roads. A railway has been built from Bobadilla to Algeciras, and other lines have been planned. The province is one of the most backward as regards education. Agriculture has not much improved, despite the fertility of the soil. In 1895, 330,380 acres were devoted to wheat, 21,250 to chick-peas and beans, and 35,000 to vines. Beetroot and sugar-cane alone have been grown in larger proportion to meet the demands of the manufacturers, which increased greatly on the loss of the colonial imports of sugar. The live stock in 1895 included 5504 horses, 9759 mules, 11,835 asses, 19,499 cattle, 62,366 sheep, 77,951 goats, 29,185 pigs. In 1898 eight iron mines had an output of 26,142 tons. There is little other mining industry, but 182 mines (141 iron) are registered, though unproductive. Manufactures have advanced somewhat, especially distilling, since the almost prohibitive duties were laid on foreign alcohols. The sugar factories are some of the most prosperous in Spain. The fisheries are important, giving occupation to about 300 boats, which bring in annually 18,000,000 lb of fish, nearly 25 per cent. of which is exported.

Malaga, the capital of the above province, is a rapidly growing seaport and a busy railway terminus. Its population was 134,016 in 1887, and in 1897, 125,434. The popularity of the town as a winter resort has increased with the spread of well-built suburbs into the rich, beautiful country that lies all around, invalids attracted by the climate being at last able to find, in the new quarters, abodes that are both healthy and pleasant. There are fine, broad streets and squares, gardens, promenades, and other improvements, due as much to private enterprise as to the municipal authorities. On the outskirts, too, are several factories that have been started for many local industries: iron foundries, distilling, and manufactures of textiles, sugar, soap, and chemicals. The trade, however, is chiefly in agricultural products, wine, and minerals. The movement of shipping in the port is considerable. In 1898 the shipping totalled 1874 vessels of 1,404,531 tons (1412 of 905,117 tons Spanish). Of the foreign shipping nearly half was British. Among the principal imports in 1898 were 27,847 tons of coal, 5897 tons of pod fruit, 3877 tons of guano, 1012 of iron of all kinds, and 395 tons of machinery. The principal exports in 1898 were olive oil 30,547 tons, almonds 1613 tons, barley 3212 tons, chick-peas 1660 tons, lemons 5056 tons, oranges 1265 tons, raisins 6516 tons, lead 23,132 tons. The quantity of wine exported was 2,234,855 gallons, a slight increase on 1897. Lemons, oranges, and wine went mostly to England; lead to France. The raisin crop was 600,000 boxes, and the

olive also increased remarkably. The wine trade has fallen off considerably, owing to a variety of reasons, but latterly the demand for the better class of least-adulterated wines has increased. After much of the general trade of the port had been lost, the harbour works have been so far completed as to enable ships of considerable size to discharge on the quays directly, and to load, as a line of railway connects them with the main system. The average depth of the harbour is 30 to 32 feet, the minimum 23 feet. The local corporations have turned into a "park" and public promenade several acres of land redeemed from the sea, have extended the use of electric light, and have developed the tramways.

Malakoff, town, arrondissement of Sceaux, department of Seine, France, lying south by west of Paris, close to the fortifications and on the road to Montrouge. The church contains a painting by Philippe de Champagne of "The Flight into Egypt." The town is quite modern, having its origin in a village named California, founded about 1848, but owing its present name to a building erected by a local benefactor, Alexander Chauvelot, which he called the Tower of Malakoff, in commemoration of that captured at Sebastopol by MacMahon. This tower was taken down in 1870, lest it should serve as a mark for the Prussians. After the war the place grew rapidly, and in 1884 it became a separate commune. Population (1896), 10,796; (1901), 14,341.

Malan, Solomon Cæsar (1812-1894), divine and Orientalist, was by birth a Swiss descended from an exiled French family, and was born at Geneva, 22nd April 1812, where his father, Dr Cæsar Malan, enjoyed a great reputation as a Protestant divine. From his earliest youth he manifested a remarkable faculty for the study of languages, and when he came to Scotland as tutor in the marquis of Tweeddale's family at the age of 18 he had already made progress in Sanskrit, Arabic, and Hebrew. In 1833 he matriculated at St. Edmund's Hall, Oxford; and English being almost an unknown tongue to him, he petitioned the examiners to allow him to do his paper work of the examination in French, German, Spanish, Italian, Latin, or Greek, rather than in English. But his request was not granted. After gaining the Boden and Pusey and Ellerton scholarships, he graduated 2nd class in *Lit. Hum.* in 1837. He then proceeded to India as classical lecturer at Bishop's College, Calcutta, to which post he added the duties of secretary to the Bengal branch of the Royal Asiatic Society; and although compelled by illness to return in 1840, laid the foundation of a knowledge of Tibetan and Chinese. After serving various curacies, he was presented in 1845 to the living of Broadwindsor, Dorset, which he held until 1886. During this entire period he continued to augment his linguistic knowledge, which he carried so far as to be able to preach in that most difficult language, Georgian, on a visit which he paid to Nineveh in 1872. His translations from the Armenian, Georgian, and Coptic were numerous; he also applied his Chinese learning to the determination of important points connected with Chinese religion, and published a vast number of parallel passages illustrative of the Book of Proverbs. In 1880 the University of Edinburgh conferred upon him the honorary degree of D.D. No modern scholar, perhaps, has so nearly approached the linguistic omniscience of Mezzofanti; but, like Mezzofanti, Dr Malan was more of a linguist than a critic. He made himself conspicuous by the vehemence of his opposition to Westcott and Hort's text of the New Testament, and to the transliteration of Oriental languages, on neither of which points did he in general obtain the suffrages of scholars. His extensive and valuable library, some special collections excepted, was presented by him

in his lifetime to the Indian Institute at Oxford. He died at Bournemouth, 25th November 1894. His life has been written by his son.
(R. G.)

Mälär, a lake of Sweden, lying immediately west of Stockholm, with an area of 449 square miles, of which 189 square miles are covered by the numerous islands which stud its waters. Length, 73 miles; breadth, one-third mile to 30 miles. Area of drainage basin, 8789 square miles, of which 1224 are occupied by lakes. The shores are deeply indented, running out in places into long winding arms. Two channels connect the lake with the Baltic—Norrström, $7\frac{1}{2}$ feet deep at low water, on the north of the old "town" of Stockholm; and Söderström, $11\frac{1}{2}$ feet deep, on the south of the same, where the out-flow is regulated by a sluice (1630). The former is the channel used by vessels up to but not exceeding 350 tons. A proposal has been made to cut a new channel out of the lake at Danvik, $3\frac{1}{4}$ miles below the Söderström sluice, where the oldest dam was constructed by Gustavus Vasa in the middle of the 16th century. The difference of level between the lake and Saltsjö (the arm of the Baltic immediately below the city) is so slight (11 inches) that not infrequently the Baltic water flows into the lake. The bottom of the lake consists of a series of basins, separated by ridges; greatest depth, 200 feet; minimum depth, 30 feet. The lake is fed by several rivers, all small, and is connected with Lake Hjelmar to the south-west (i.) by the Arboga river and the Hjelmar canal, and (ii.) by the Eskilstuna river and the Thorshälla canal (1856-1860). It also has navigable connexion with the Baltic through the Södertelge canal (10 feet minimum depth). On the shores of Lake Mälär stand, besides Stockholm, the historic cities of Sigtuna, Vesterås, and Strengnäs; further, the royal castles of Drottningholm (on Lof Island) and Gripsholm, the former built in the 17th century, the latter in 1537. Gripsholm is now, however, a museum of antiquities.

See G. NERMAN, in *Ymer* (1897); and *Bihang till Kong. Svensk. Vetensk. Akad. Handlingar* (1895 and 1896); also, for the forcing of the Norrmalm (Stoksund) by St Olaf, king of Norway, in the year 1007, *Heimskringla*, chap. iv.

Malaria.—From the time of Hippocrates onwards the malarial or periodical fevers have engaged the attention of innumerable observers, who have suggested various theories of causation, and have sometimes anticipated—vaguely, indeed, but with surprising accuracy—the results of modern research; but the true nature of the disease remained in doubt until the closing years of the 19th century. It has now been demonstrated by a series of accurate investigations, contributed by many workers, that malaria is caused by a microscopic parasite in the blood, into which it is introduced by the bites of certain species of mosquito. Many points still remain to be explained, and the mosquito theory has not yet been universally accepted as covering the whole ground; but the main fact that malaria is so caused has been established beyond question, and it goes far to explain much that has hitherto been obscure. The discovery has also greatly stimulated the general study of this destructive group of diseases, particularly in the direction of prevention.

The successive steps by which the present position has been reached form an interesting chapter in the history of scientific progress. The first substantial link in the actual chain of discovery was contributed in 1880 by Laveran, a French army surgeon serving in Algeria. On the 6th of November in that year he plainly saw the living parasites under the microscope in the blood of a malarial patient, and he shortly afterwards communicated his observations to the Paris

History of discovery.

Académie de Médecine. They were confirmed, but met with little acceptance in the scientific world, which was preoccupied with the claims of a subsequently discredited *Bacillus malarie*. In 1885 the Italian pathologists came round to Laveran's views, and began to work out the life-history of his parasites. The subject has a special interest for Italy, which is devastated by malaria, and Italian science has contributed materially to the solution of the problem. The labours of Golgi, Marchiafava, Celli, and others established the nature of the parasite and its behaviour in the blood; they proved the fact, guessed by Rasori so far back as 1846, that the periodical febrile paroxysm corresponds with the development of the organisms; and they showed that the different forms of malarial fever have their distinct parasites, and consequently fall into distinct groups, defined on an etiological as well as a clinical basis—namely, the mild or spring group, which includes tertian and quartan ague, and the malignant or “æstivo-autumnal” group, which includes a tertian or a semi-tertian and the true quotidian type. Three distinct parasites, corresponding with the tertian, quartan, and malignant types of fever, have been described by Italian observers, and the classification is generally accepted; intermediate types are ascribed to mixed and multiple infections. So far, however, only half the problem, and, from the practical point of view, the less important half, had been solved. The origin of the parasite and its mode of introduction into the blood remained to be discovered. An old popular belief current in different countries, and derived from common observation, connected mosquitoes with malaria, and from time to time this theory found support in more scientific quarters on general grounds, but it lacked demonstration and attracted little attention. In 1894, however, Manson, arguing with greater precision by analogy from his own discovery of the cause of filariasis and the part played by mosquitoes, suggested that the malarial parasite had a similar intermediate host outside the human body, and that a suctorial insect, which would probably be found to be a particular mosquito, was required for its development. Following up this line of investigation, Ross in 1895 found that if a mosquito sucked blood containing the parasites they soon began to throw out flagellæ, which broke away and became free; and in 1897 he discovered peculiar pigmented cells, which afterwards turned out to be the parasites of æstivo-autumnal malaria in an early stage of development, within the stomach-wall of mosquitoes which had been fed on malarial blood. He further found that only mosquitoes of the genus *Anopheles* had these cells, and that they did not get them when fed on healthy blood. Then, turning his attention to the malaria of birds, he worked out the life-history of these cells within the body of the mosquito. “He saw that they increased in size, divided, and became full of filiform spores, then ruptured and poured out their multitudinous progeny into the body-cavity of their insect host. Finally, he saw the spores accumulate within the cells of the salivary glands, and discovered that they actually passed down the salivary ducts and along the grooved hypopharynx into the seat of puncture, thus causing infection in a fresh vertebrate host” (Sambon). To apply these discoveries to the malaria of man was an obvious step. In working out the details the Italian school have again taken a prominent part.

Thus we get a complete scientific demonstration of the causation of malaria in three stages: (1) the discovery of the parasite by Laveran; (2) its life-history in the human host and connexion with the fever demonstrated by the Italian observers; (3) its life-history in the alternate host, and the identification of the latter with a particular species of mosquito by Ross and Manson. The conclusions derived

from the microscopical laboratory were confirmed by actual experiment. In 1898 it was conclusively shown in Italy that if a mosquito of the *Anopheles* variety bites a person suffering from malaria, and is kept long enough for the parasite to develop in the salivary gland, and is then allowed to bite a healthy person, the latter will in due time develop malaria. The converse proposition, that persons efficiently protected from mosquito bites escape malaria, has been made the subject of several remarkable experiments. One of the most interesting was carried out in 1900 for the London School of Tropical Medicine by Dr Sambon and Dr Low, who went to reside in one of the most malarious districts in the Roman Campagna during the most dangerous season. Together with Signor Terzi and two Italian servants, they lived from the beginning of July until the 19th of October in a specially protected hut, erected near Ostia. The sole precaution taken was to confine themselves, between sunset and sunrise, to their mosquito-proof dwelling. All escaped malaria, which was rife in the immediate neighbourhood. Mosquitoes caught by the experimenters, and sent to London, produced malaria in persons who submitted themselves to the bites of these insects at the London School of Tropical Medicine. Experiments in protection on a larger scale, and under more ordinary conditions, have been carried out with equal success by Professor Celli and other Italian authorities. The first of these was in 1899, and the subjects were the railway-men employed on certain lines running through highly malarious districts. Of 24 protected persons, all escaped but four, and these had to be out at night or otherwise neglected precautions; of 38 unprotected persons, all contracted malaria except two, who had apparently acquired immunity. In 1900 further experiments gave still better results. Of 52 protected persons on one line, all escaped except two, who were careless; of 52 protected on another line, all escaped, while of 51 unprotected persons, living in alternate houses, all suffered except seven. Out of a total of 207 persons protected in these railway experiments, 197 escaped. In two peasants' cottages in the Campagna, protected with wire netting by Professor Celli, all the inmates—10 in number—escaped, while the neighbours suffered severely; and three out of four persons living in a third hut, from which protection was removed, owing to the indifference of the inmates, contracted malaria. In the malarious islet of Asinara a pond of stagnant water was treated with petroleum and all windows were protected with gauze. The result was that the houses were free from mosquitoes, and no malaria occurred throughout the entire season, though there had been 40 cases in the previous year. Eight Red Cross ambulances, each with a doctor and attendant, were sent into the most malarious parts of the Campagna in 1900. By living in protected houses and wearing gloves and veils at night, all the staff escaped malaria except one or two attendants. These and other experiments, described by Dr Manson in the *Practitioner* for March 1900, confirming the laboratory evidence as they do, leave no doubt whatever of the correctness of the mosquito-parasitic theory of malaria. It is possible, though not probable, that malaria may also be contracted in some other way than by mosquito bite, but there are no well-authenticated facts which require any other theory for their explanation. The alleged occurrence of the disease in localities free from mosquitoes or without their agency is not well attested; its absence from other localities where they abound is accounted for by their being of an innocent species, or—as in England—free from the parasite. The old theory of paludism or of a noxious miasma exhaled from the ground

*Experi-
ment.*

is no longer necessary. The broad facts on which it is based are sufficiently accounted for by the habits of mosquitoes. For instance, the swampy character of malarial areas is explained by their breeding in stagnant water; the effect of drainage, and the general immunity of high-lying, dry localities, by the lack of breeding facilities; the danger of the night air, by their nocturnal habits; the comparative immunity of the upper storeys of houses, by the fact that they fly low; the confinement of malaria to well-marked areas and the diminution of danger with distance, by their habit of clinging to the breeding-grounds, and not flying far. Similarly, the subsidence of malaria during cold weather and its seasonal prevalence find an adequate explanation in the conditions governing insect life. At the same time it should be remembered that many points await elucidation, and it is unwise to assume conclusions in advance of the evidence.

With regard to the parasites which are the actual cause of malaria in man, an account of them is given under the heading of PATHOLOGY (*Parasitic Diseases*), and little need be said about them here. They belong to the group of Protozoa, and, as already explained, have a double cycle of existence: (1) a sexual cycle in the body of the mosquito, (2) an asexual cycle in the blood of human beings. They occupy and destroy the red corpuscles, converting the hæmoglobin into melanin; they multiply in the blood by sporulation, and produce accessions of fever by the liberation of a toxin at the time of sporulation (Ross). The number in the blood in an acute attack is reckoned by Ross to be not less than 250 millions. A more general and practical interest attaches to the insects which act as their intermediate hosts. These mosquitoes or gnats—the terms are synonymous—belong to the family *Culicidæ* and the genus *Anopheles*, which was first classified by Meigen in 1818. It has a wide geographical distribution, being found in Europe (including England), Asia Minor, Burma, Straits Settlements, Java, China, Formosa, Egypt, West, South, and Central Africa, Australia, South America, West Indies, United States, and Canada, but is generally confined to local centres in those countries. About fifty species are recognized at present. It is believed that all of them may serve as hosts of the parasite. The species best known in connexion with malaria are *A. maculipennis* (Europe and America), *A. funestus*, and *A. costales* (Africa). In colour *Anopheles* is usually brownish or slaty, but sometimes buff, and the thorax frequently has a dark stripe on each side. The wings in nearly all species have a dappled or speckled appearance, owing to the occurrence of blotches on the front margin and to the arrangement of the scales covering the veins in alternating light and dark patches (Austen). The genus with which *Anopheles* is most likely to be confounded is *Culex*, which is the commonest of all mosquitoes, has a world-wide distribution, and is generally a greedy blood-sucker. A distinctive feature is the position assumed in resting; *Culex* has a hump-backed attitude, while in *Anopheles* the proboscis, head, and body are in a straight line, and in many species inclined at an angle to the wall, the tail sticking outwards. In the female of *Culex* the palpi are much shorter than the proboscis; in *Anopheles* they are of the same length. The wings in *Culex* have not the same dappled appearance. *Anopheles* is also a more slender insect, with a smaller head, narrower body, and thinner legs. There are further differences in the other stages of life. Mosquitoes go through four phases: (1) ovum, (2) larva, (3) nymph, (4) complete insect. The ova of *Anopheles* are tiny black rod-shaped objects, which are deposited on the water of natural puddles, ponds, or slowly-moving streams, by preference those which are well supplied with vegetation;

they float singly or attached to other objects or clustered together in patterns. They can live in brackish, and even in sea water. The larva has no breathing-tube, and floats horizontally at the surface, except when feeding; it does not frequent sewage or foul water. The ova of *Culex*, on the other hand, are deposited in any stagnant water, including cesspools, drains, cisterns, or water collected in any vessel; they float in boat-shaped masses on the surface. The larva has a breathing-tube, and floats head downwards; when disturbed, it wriggles to the bottom (Christy). Some observers maintain that *Anopheles* does not “sing” like the common mosquito, and its bite is much less irritating. Only the females suck blood; the act is believed to be necessary for fertilization and reproduction. *Anopheles* rarely bites by day, and then only in dark places. In the daytime “the gorged females rest motionless on the walls and ceilings of rooms, choosing always the darkest situations for this purpose” (Austen). In temperate climates the impregnated females hibernate during the winter in houses, cellars, stables, the trunks of trees, &c., coming out to lay their eggs in the spring. The four phases are passed in thirty days in a favourable season, and consequently there are ordinarily four or five generations from April to September (Celli).

The most important question raised by the mosquito-parasitic theory of malaria is that of prevention. This may be considered under two heads: (1) individual prophylaxis; (2) administrative prevention on a large scale.

(1) In the first place, common sense suggests the avoidance, in malarious countries, of unhealthy situations, and particularly the neighbourhood of stagnant water. Among elements of unhealthiness is next to be reckoned the proximity of native villages, the inhabitants of which are infected. In the tropics “no European house should be located nearer to a native village than half a mile” (Manson); and since children are almost universally infected, “the presence of young natives in the house should be absolutely interdicted” (Manson). When unhealthy situations cannot be avoided, they may be rendered more healthy by destroying the breeding-grounds of mosquitoes in the neighbourhood. All puddles and collections of water should be filled in or drained; as a temporary expedient they may be treated with petroleum, which prevents the development of the larvæ. When a place cannot be kept free from mosquitoes the house may be protected, as in the experiments in Italy, by wire gauze at the doors and windows. The arrangement used for the entrance is a wire cage with double doors. Failing such protection mosquito curtains should be used. Mosquitoes in the house may be destroyed by the fumes of burning sulphur or tobacco smoke. According to the experiments of Celli and Casagrandi, these are the most effective culicidæ; when used in sufficient quantity they kill mosquitoes in one minute. The same authorities recommend a powder composed of larvicide (an aniline substance), chrysanthemum flowers, and valerian root, to be burnt in bedrooms. Anointing the skin with strong-smelling substances is of little use in the open air, but more effective in the house; turpentine appears to be the best. Exposure at night should be avoided. All these prophylactic measures are directed against mosquitoes. There remains the question of protection against the parasite. Chills are recognized as predisposing both to primary infection and to relapses, and malnutrition is also believed to increase susceptibility; both should therefore be avoided. Then a certain amount of immunity may be acquired by the systematic use of quinine. Manson recommends five to ten grains once or twice a week; Ross recommends the same quantity every day before breakfast.

Prophylaxis.

There is some evidence that arsenic has a prophylactic effect. An experiment made on the railway staff at Bovino, a highly malarious district on the Adriatic, gave a striking result. The number of persons was 78, and they were divided into two equal groups of 39 each. One group was treated with arsenic, and of these 36 escaped altogether, while three had mild attacks; the remaining 39, who were not treated, all had fever. In a more extended experiment on 657 railway-men, 402 escaped. This was in 1889, but in spite of the encouraging results the use of arsenic does not appear to have made any further progress. Experiments in immunizing by sero-therapeutic methods have not as yet met with success.

(2) Much attention has been directed in scientific circles to the possibility of "stamping out" epidemic malaria by administrative measures. The problem is one of great practical importance, especially to the British empire. There are no data for estimating the damage inflicted by malaria in the British colonies. It is, indeed, quite incalculable. In Italy the annual mortality from this cause averages 15,000, which is estimated to represent two million cases of sickness and a consequent loss of several million francs. In British tropical possessions the bill is incomparably heavier. There is not only the heavy toll in life and health exacted from Europeans, but the virtual closing of enormous tracts of productive country which would otherwise afford scope for British enterprise. The "deadly" climates, to which so much dread attaches, generally mean malaria, and the mastery of this disease would be equivalent to the addition of vast and valuable areas to the empire. The problem, therefore, is eminently one for the statesman and administrator. A solution may be sought in several directions, suggested by the facts already explained. The existence of the parasite is maintained by a vicious interchange between its alternate hosts, mosquitoes and man, each infecting the other. If the cycle be broken at any point the parasite must die out, assuming that it has no other origin or mode of existence. The most effective step would obviously be the extermination of the *Anopheles* mosquito. A great deal may be done towards this end by suppressing their breeding-places, which means the drying of the ground. It is a question for the engineer, and may require different methods in different circumstances. Put comprehensively, it involves the control of the subsoil and surface waters by drainage, the regulation of rivers and floods, suitable agriculture, the clearing of forests or jungles, which tend to increase the rainfall and keep the ground swampy. The city of Rome is an example of what can be done by drainage; situated in the midst of malaria, it is itself quite healthy. A systematic campaign for the destruction of breeding-places has been inaugurated in the British West African colonies, with encouraging results. The planting of eucalyptus trees is out of favour at present, but it appears to have been successful in Portugal, not from any prophylactic virtues in the plant, but through the great absorption of moisture by its deep roots, which tend to dry the subsoil. Treating the breeding-ponds with petroleum or similar preparations seems to be hardly applicable on a large scale, and in any case can only be a temporary expedient. Short of suppressing mosquitoes, the parasitic circle may theoretically be broken by preventing them from giving the infection to man or taking it from him. The means of accomplishing the former have been already pointed out, but they are obviously difficult to carry out on a large scale, particularly in native communities. It is one thing to protect individuals from mosquito bites, another to prevent the propagation of the parasite in a whole community. Perhaps the converse is more feasible

in some circumstances—that is to say, preventing mosquitoes from having access to malarial persons, and so propagating the parasite in themselves. It could be carried out where the infected persons are few, by isolating and protecting them, but not where many are infected, as in native villages. Koch has suggested that the disinfection of malarial persons by quinine would have the desired effect, but other authorities of greater experience do not consider it practicable. In spite of the difficulties, however, there is no doubt that a great deal can be done to reduce, if not stamp out, malaria by the methods indicated, which should be applied according to circumstances. An encouraging example is afforded by the remarkable fact that malaria, which was once rife in certain districts of England, has now died out, although the *Anopheles maculipennis* mosquito still exists there. The parasitic cycle has been broken, and the insect is no longer infected. The suggested causes are (1) reduction of insects by drainage, (2) reduced population, (3) the use of quinine. Dr Manson has suggested that the problem of stamping out malaria may be assisted by the discovery of some at present unknown factors. He has pointed out that certain areas and certain islands are entirely free from the disease, while neighbouring areas and islands are devastated. This immunity is apparently not due to the absence of favourable conditions, but rather to the presence of some inimical factor which prevents the development of the parasite. If this factor could be discovered it might be applied to the suppression of the disease in malarious localities.

A few other points may be noted. The pathological changes in malaria are due to the deposition of melanin and the detritus of red corpuscles and hæmoglobin, and to the congregation of parasites in certain sites (Ross). In chronic cases the eventual effects are anæmia, melanosis, enlargement of the spleen and liver, and general cachexia. Apparently the parasites may remain quiescent in the blood for years, and may cause relapses by fresh sporulation. Recent discoveries have done little or nothing for treatment. Quinine still remains the one specific. In serious cases it should not be given in solid form, but in solution by the stomach, rectum, or—better—hypodermically (Manson). According to Ross, it should be given promptly, in sufficient doses (up to 30 grains), and should be continued for months. Equinine is by some preferred to quinine, but it is more expensive. The nature of immunity is not known. Some persons are naturally absolutely immune (Celli), but this is rare; immunity is also sometimes acquired by infection, but as a rule persons once infected are more predisposed than others. Races inhabiting malarious districts acquire a certain degree of resistance, no doubt through natural selection. Children are much more susceptible than adults.

Blackwater fever is a disease occurring in tropical countries and elsewhere, which is often classed with malaria. It is characterized by irregular febrile paroxysms, accompanied by rigors, bilious vomiting, jaundice, and hæmoglobinuria (Sambon). It has a wide geographical distribution, including tropical Africa, parts of Asia, the West Indies, the southern United States, and—in Europe—Greece, Sicily, and Sardinia; but its range is not coextensive with malaria. Malarial parasites have occasionally been found in the blood. Some authorities believe it to be caused by the excessive use of quinine, taken to combat malaria. This theory has the support of Koch, but is not generally accepted. If it were correct, one would expect blackwater fever to be regularly prevalent in malarial countries and to be more or less coextensive with the use of quinine, which is not at all the case. It often resembles yellow fever, but the characteristic black vomit

of yellow fever rarely occurs in blackwater fever, while the black urine from which the latter derives its name is equally rare in the former. According to the new school of tropical parasitology, blackwater fever is neither a form of malaria nor produced by quinine, but a specific disease due to a protozoal parasite not yet identified, but akin to that which causes the redwater fever of cattle.

Malaria in the Lower Vertebrates.—Birds are subject to malaria, which is caused by blood parasites akin to those in man and having a similar life-history. Two species, affecting different kinds of birds, have been identified. Their alternate hosts are mosquitoes of the *Culex* genus. Oxen, sheep, dogs, monkeys, bats, and probably horses also suffer from similar parasitic diseases. In the case of oxen the alternate host of the parasite is a special tick (Smith and Kilborne). In the other animals several parasites have been described by different observers, but the alternate hosts are not known.

AUTHORITIES.—CELLI. *Malaria.*—CHRISTY. *Mosquitoes and Malaria.*—MANSON. *Tropical Diseases.*—Appendix to Allbutt's *System of Medicine.*—ROSS. "Malaria," Quain's *Dictionary of Medicine*, 3rd edition.—*The Practitioner*, March 1901 (Malaria Number).

Malatia, or ASPUZU, the chief town of a sanjak of the same name in the Memuret el-Aziz vilayet of Asia Minor, and a military station on the Samsun-Sivas-Diarbekr road, altitude 2900 feet, situated about 10 miles south-west of the junction of the Tokhma Su with the Euphrates, near the south end of a fertile plain. It has been rebuilt since the earthquake of 1893, contains fine public buildings, and is noted for its fruit orchards. There are Protestant (American) and Roman Catholic missions. During the massacres of 1895 about 3000 Gregorian and Protestant Armenians perished, and many churches and houses were destroyed. The population comprises 26,800 Moslems, Kúrds, and Kizilbash, and 3200 Armenians. Old Malatia (*Melitene*), which lies 5 miles to the north-east, is deserted. The earliest site was possibly Arslan Tepe, where "Hittite" remains have been found.

Malay Archipelago.—The Malay, or Indian, Archipelago, as now restricted, ethnogeographically includes the Sunda Islands, the Moluccas, New Guinea, and the Philippine Islands, but excludes the Andaman-Nicobar group. Politically the whole of the archipelago (except a moiety of Borneo (British) and of Timor (Portuguese), New Guinea, east of the 141st meridian (British and German), and the Philippine Islands), belongs to the Netherlands. The Philippine Islands, which had been for several centuries a possession of the Spanish Crown, passed in 1898 by conquest to the United States of America.

In regard to the extent and population of the archipelago, the area of the Dutch possessions has been computed to be rather less than formerly stated; but the population has greatly increased.

	Area.	Population.	
		1897.	1900.
Sunda Islands	459,578	32,500,000	32,632,400
Moluccas, with Celebes	115,334	2,397,000	3,000,000
New Guinea	151,789	800,000	800,000 ¹
Philippine Islands	11,440	7,450,000	8,000,000

In regard to physical geography, the result of investigations in the island of Celebes, which was considered to belong to the eastern (or Austro-Malayan) biological sub-region, proves it to have a somewhat closer affinity with the Indian region, so that it would seem to have been

¹ Estimate.

connected longer with Asian than with the Australasian lands.

The most notable fact in the geological history of the archipelago is the discovery in Java of the fossil remains of *Pithecanthropus erectus*, a form intermediate between the higher apes and man. In its structure and cranial capacity it is entitled to a higher place in the zoological scale than any anthropoid, for it walked almost certainly erect; and, on the other hand, in its intellectual powers it must have been much below the lowest of the human race at present known. The strata in which it was found belong to the Miocene or Upper Pliocene. Another notable event, unprecedented even in the history of so volcanic a region as the archipelago, was the disastrous eruption of Krakatoa in 1883, a little island-crater situated in the Strait of Sunda, between Java and Sumatra. The effects of the eruption were recognizable over a wider area of the globe than any other on record. The noise of the final explosion travelled farther than any previous sound is known to have reached. The marine and aerial waves generated by it travelled several times round the globe, and some of the debris projected into the atmosphere—causing in many parts of the world very brilliant sunset effects—fell even in Europe.

Ethnologically some considerable advances in our knowledge of the races of the Indian Archipelago have been made. The Malays (*q.v.*) predominate in the Sunda Islands, and have spread sporadically over the eastern half of the archipelago, in which the Melanesian is now the race of the soil. "The Malays, as known to us in the purer Atjinese and Sundanese—a race developed through the commingling of Caucasian and predominating Mongol blood in Indo-China—were the last incursionists into the region. They followed an earlier pure Caucasian migration, known as Polynesians, whose last remnants in the archipelago linger in the Mentawi Islands on the west coast of Sumatra, who drove the Negrito autochthones of the archipelago out into the remote interior of the Philippine and other islands, and were themselves overwhelmed by the half-breeds of Mongol and predominating Caucasian blood, now known as Indonesians, of whom the Battaks and Dyaks are survivors. In like manner the Melanesians of the Solomon and New Hebrides Islands, migrating westwards over the eastern part of the archipelago, partly supplanted, partly commingled with the Negrito autochthones and these Caucasian (Polynesian) pre-incursionists, whose strain appears still in many of the people, as well in their language as in their customs." (Forbes.)

Here we shall deal with the Dutch East Indies as a whole, the different islands being considered under their own headings.

The Dutch possessions in Asia lie between 6° N. and 11° S. and 95° E. and 141° E. Politically they are divided into lands under the direct government of the Netherlands, vassal lands, and confederated lands. Administratively they are further divided into residencies, divisions, regencies, districts, and *dessas* or villages. They are often described as of two groups, Java and Madura forming one, and the other consisting of Sumatra, Borneo, Riouw-Lingga Archipelago, Banca, Billiton, Celebes, Molucca Archipelago, the small Sunda Islands, and a part of New Guinea—the Outposts as they are collectively named. A governor-general holds the superior administrative and executive authority, and is assisted by a council of five members, partly of a legislative and partly of an advisory character, but with no share in the executive work of the government. The governor-general not only has supreme executive authority, but can of his own accord pass laws and regulations, except in so far as these, from their nature, belong of right to the home government, and as he is bound by the constitutional principles on which, according to the *Regulations for the Government of Netherlands India*, passed by the king and States-General in 1854, the Dutch East Indies must be governed. The following table gives the area and population of Java (including Madura) and of the Outposts:—

	Area: English Square Miles.	Population in 1897.	Density per Square Mile.	
Java and Madura	50,554	26,125,053	517	
Island of Sumatra	Sumatra, West Coast	31,649	1,353,515 ¹	42
	Sumatra, East Coast	35,312	335,432 ²	9
	Bencoolen	9,399	158,767 ²	17
	Lampung	11,284	137,501 ¹	12
	Palembang	53,497	692,317 ¹	13
Atjeh	20,471	531,705 ²	26	
Riouw-Lingga Archipelago	16,301	107,861 ²	6	
Banca	4,446	93,600 ¹	21	
Billiton	1,863	41,558 ¹	22

Molucca Islands	43,864	399,208 ²	9	
Timor Archipelago	17,698	119,239 ²	6	
Bali and Lombok	4,065	1,044,757 ³	256	
New Guinea to 141° E. long. ⁴	151,789	200,000 ³	1	
Total	736,399	34,518,951 ⁵	40	

The total number of Europeans and persons assimilated to them at the beginning of 1896 was 35,489 males and 27,826 females; of these 33,055 males and 27,222 females were Dutch, of whom 25,351 males and 23,648 females were born in the East Indies; of the remainder, 1192 were German, 300 French, 318 English, 184 Swiss, 292 Belgians; the remainder being mostly Austrians and Armenians. Of the remaining population about 469,500 were Chinese, 24,400 Arabs, and 11,600 other Orientals, and the rest natives.

The movement of population between Europeans and persons assimilated to them was as follows:—

	Marriages.	Births.	Deaths.
1889 { Java and Madura	443	2126	1473
Outposts	122	626	904
1894 { Java and Madura	541	2343	1192
Outposts	109	691	387
1898 { Java and Madura	647	1916	1227
Outposts	111	489	484

The population of the principal towns in January 1897 was:—

	Europeans.	Natives.	Chinese.	Arabs.	Other Orientals.	Total.
Batavia	9423	76,751	26,433	2828	132	115,567
Samarang	3355	67,236	11,870	765	1040	84,266
Surabaya ⁶	6988	121,075	12,133	2332	452	142,980
Surakarta	1370	79,802	4,571	85	246	86,074
Jokjakarta	2240	54,219	3,836	86	142	60,523
Palembang	243	46,655	4,463	1797	125	53,283

Religion and Instruction.—Entire liberty is granted to the members of all religious confessions. In 1899 the Reformed Church counted 37 ministers and 24 assistants, the Roman Catholic 31 curates and 17 priests, not salaried out of the public funds. The number of Christians among the natives and foreign Orientals was:—

In Java and Madura in 1873 . . . 5,673, and in 1896 . . . 19,193
 „ the Outposts . . . 148,672 „ „ . . . 290,065

In 1900, 141 missionaries of various societies were working to propagate Christianity in the Dutch East Indies. In 1899, 7694 natives went to Mecca on pilgrimage, of whom 6652 returned.

For the education of Europeans and persons assimilated with them there were, in 1899, 7 public middle-class schools, with 1051 pupils and 118 teachers. The cost of these schools to the Government in the same year was 591,332 guilders, and the revenue out of the school fees 87,211 guilders. In 1899 there were for Europeans 135 mixed public elementary schools, and 30 for girls only, with 20 private schools, or a total of 185 elementary schools. The 165 public schools had a teaching staff of 546, and an attendance of 15,132 pupils, whereof 1626 were natives; and the 20 private

schools a teaching staff of 166, and an attendance of 3270 pupils. The cost of the public elementary schools was, in 1899, 2,546,529, and the income 284,095 guilders.

The following statement relates to schools for natives:—In 1899 Dutch India had 5 normal schools, with 27 teachers and 144 pupils; besides, there were 4 schools for sons of native chiefs, with 202 pupils. The elementary schools for natives were, for Java and Madura, in 1875: 104 Government schools with 14,906 pupils, and 132 private schools with 6978 pupils; and in 1899, 232 Government schools with 40,956 pupils, and 236 private schools with 26,524 pupils.⁷ In the Outposts in 1881, 281 Government schools with 21,388 pupils, and 205 private schools with 10,696 pupils; and in 1898, 297 Government schools with 44,259 pupils, and 546 private schools with 26,847 pupils.

In 1875 the Government spent 803,906 guilders for the education of natives, and in 1899, 1,501,291 guilders. For foreign Orientals there were in 1899, 434 schools with 7637 pupils.

Justice and Crime.—The administration of justice is based on the principle that Europeans and persons assimilated with them are subject to laws nearly similar to those of the mother country, while the natives are subject to their own customs and institutions. The administration of justice for Europeans is entrusted to European judges, while for natives their own chiefs have a large share in the trial of cases. There is a High Court of Justice at Batavia—courts of justice at Batavia, Samarang, Surabaya, Padang, and Macassar—resident and regent courts, courts of circuit, district courts, and courts of priests. There are about 300 prisons; their population was 24,712 at the end of 1898. The relations of the state to pauperism are limited to subvention to Protestant and Catholic orphan houses; for this purpose the budget contains about 100,000 guilders yearly.

Finance.—The local revenue is derived from land, taxes on houses and estates, from licences, customs duties, personal imposts, the Government monopolies of salt and opium, railways, and a number of indirect taxes. But the chief part of the large profits is indirect, being obtained by the sale of a vast amount of coffee, grown under the “culture system,” and sold in India and Europe.

The following table shows the revenue and expenditure for 1880, 1890, and 1900:—

Year.	Revenue.	Expenditure.	Surplus or Deficit.
	Guilders.	Guilders.	Guilders.
1880	146,838,000	146,936,000	— 98,000
1890	137,789,482	127,736,739	+ 10,052,743
1900	141,980,008	147,766,255	— 5,777,247

About one-third of the annual expenditure is for the army and navy, and another third for the general administration, both in Java and in the Netherlands.

Defence.—The army is purely colonial, and comprised at the end of 1899, 1345 officers and 39,388 non-commissioned officers and men, of whom 14,960 were Europeans, 45 Africans, 4251 Amboinese, and 20,132 natives. The number of horses was 1346. No portion of the regular army of the Netherlands is allowed to be sent on colonial service, but individual soldiers are at liberty to enlist, by permission of their commanding officers, and they form the nucleus of the army of Dutch India. Native and European soldiers are generally mixed together in the same battalions, though in separate companies. The artillery is composed of European gunners, with native riders, while the cavalry are Europeans and natives. A military academy is established at Meester Cornelis, near Batavia. Schools for soldiers are attached to every battalion. Unlike the army, which is purely colonial, the navy in Dutch India is partly colonial, partly belonging to the royal navy, and its expenses are therefore borne partly by the mother country and partly by the colony. The *personnel* in the Dutch Indies numbered in 1899 about 3300 men, thus divided: 1300 Europeans and 700 natives with the Indian marine (20 ships); about 1100 Europeans and 200 natives with the auxiliary squadron (4 ships).

Production and Industry.—The greater part of the soil of Java is claimed as Government property, and it is principally in the residencies in the western part of Java that there are private estates, chiefly owned by Europeans and by Chinese. The bulk of the people are agricultural labourers. The Government or private landowners can enforce one day's gratuitous work out of seven, or more, from all the labourers on their estates; in 1882 the greater part of these enforced services for the Government was abolished, in return for the payment of one guilder per head yearly. Great power is vested in the Resident and his European and native officials to enforce a strict adherence to all the laws regulating labour.

¹ Tolerably accurate. ² Approximately. ³ Mere conjecture.

⁴ New Guinea belongs to the residency of Ternate, Molucca Islands.

⁵ Approximate total. The population of several unexplored countries is not included.

⁶ This is presumably the population of the town of Surabaya and its environs.

⁷ The returns of six private schools are not included in this total.

The extent of the soil of Java and Madura regularly cultivated by the natives was, in 1899, 6,935,300 acres (1 $\frac{3}{4}$ acre=1 bahu). The total areas in acres under the several crops in 1899 were as follows:—rice, 5,199,160; maize, arachis, cotton and various plants, 4,331,330; sugar-cane, 265,380; tobacco, 265,810; indigo, 61,000. Thus the total area under these kinds of cultivation was 10,122,680 acres.

Owing to the "agrarian law" (1870), which has afforded opportunity to private energy for obtaining waste lands on hereditary lease (*emphyteusis*) for seventy-five years, private agriculture has greatly increased both in Java and in the Outposts. In 1899 there were ceded to 785 companies and Europeans, 967,155 acres; to 52 Chinese, 33,292 acres; to 6 natives, 2319 acres—total, 1,002,766 acres. Since 1816 no land in Java has been alienated by the Government. The lands now the property of Europeans have an extent of 2,241,170 acres; of Chinese, 470,810 acres; and of other foreign Orientals, 35,650 acres.

In 1891 the government ceased to cultivate sugar. The sugar is grown on lands hired from the natives, or on lands held on emphyteutic tenure from the Government, or on private properties. In 1891 the number of sugar estates was 211; in 1899, 207. The yield of sugar since 1894 has been as follows:—

Year.	Pounds.	Year.	Pounds.	Year.	Pounds.
1894	1,076,431,400	1896	1,126,774,900	1898	1,538,701,400
1895	1,230,003,700	1897	1,220,605,200	1899	1,608,718,400

The production of coffee in Dutch India in the years 1894-99 was, in pounds:—

Year.	Government Lands.	Free Cultivation by Natives.	Lands on Emphyteusis and on Lease.	Private Lands.	Total.
1894	52,043,252	15,671,148	60,840,919	8,277,151	131,832,500
1895	43,833,858	13,564,994	48,559,186	8,765,239	114,223,277
1896	42,164,666	10,668,066	58,309,888	4,928,000	116,065,065
1897	68,338,400	12,947,200	70,228,600	4,994,666	156,508,866
1898	17,676,800	9,814,800	27,978,600	5,104,400	60,569,600
1899	82,988,533	7,884,800	69,646,000	7,609,467	118,128,800

In 1890, 8 Government plantations produced 588,018 lb of cinchona; 118 plantations held on emphyteusis, 5,360,025 lb; 2 private plantations, 58,472 lb. In 1899 the 8 Government plantations produced 878,891 lb; 85 plantations held on emphyteusis, 8,997,238 lb; and 5 private plantations, 1,261,508 lb. Of tobacco, 31,630,211 lb were produced from 102 plantations in Java in 1890; in Sumatra (Deli, &c.), 46,237,261 lb from 276 plantations. In 1899, 53,562,600 lb were produced from 131 plantations in Java, and 52,708,410 lb from 130 plantations in Sumatra (Deli, &c.). Java further produced 9,083,870 lb of tea in 1893, and 11,996,100 in 1899 (110 plantations); also 1,398,895 lb of indigo in 1890, and 1,722,890 lb in 1899 (129 plantations). The tin mines of Banca are worked by the Government, those of Billiton and Riouw by private enterprise. The total yield increased from 12,212 tons in 1890-91 to 16,460 tons in 1899-1900. The principal coal mines in Java, Sumatra, and Borneo yielded only 5489 tons in 1890, but 128,849 tons in 1895, and, with a steady increase, 185,636 tons in 1899, of which 181,325 tons, or 98 per cent. of the whole, came from the Ombilien coalfields in Sumatra. The production of the principal mineral oil enterprises was 1,627,560 gallons in 1891, of which 997,920 gallons came from the east coast of Sumatra; and 66,021,560 gallons in 1898, of which 45,635,480 gallons came from the east coast of Sumatra, and 20,381,020 gallons from Java (Rembang and Surabaya); but in 1899 the total production fell to 43,903,860 gallons.

At the end of 1895 there were in Java in all about 2,643,000 buffaloes, 2,572,000 oxen and cows, and 485,500 horses. Horses are never used in India for agricultural purposes.

In 1899 there were 49 printing offices, 70 ice and soda water manufactories, 29 soap factories, 9 arrack distilleries, 15 saw-mills, and 91 rice mills.

Commerce.—The values of the imports and of the exports in 1885, 1895, and 1899 are given below in guilders:—

	1885.	1895.	1899.
Imports	138,867,785	161,530,294	191,322,270
Exports	188,071,688	225,087,810	250,923,258

The principal articles of export are sugar, coffee, tea, rice, indigo, cinchona, tobacco, and tin. With the exception of rice, about one-half of which is shipped to Borneo and China, nearly four-fifths of these exports go to the Netherlands.

Shipping.—The following table shows the navigation at the various ports of Netherlands India in 1897 and 1898, and the share of Great Britain in it:—

Year.	Description of Vessel.	Entered.		Whereof, from Great Britain.	
		Number.	Tons.	Number.	Tons.
1895	Steamers	3418	1,366,077	370	416,607
	Sailing vessels	215	139,223	33	50,177
1899	Steamers	3661	1,635,689	330	527,209
	Sailing vessels	389	84,452	24	27,915

Communications.—At the end of 1899 the total length of railways (state and private) opened for traffic was about 1300 English miles; the revenues were 17,278,000 guilders. There are about 220 post-offices; the number of letters carried in 1899 for internal intercourse was 10,674,898, while 6,774,534 newspapers, samples, &c., for the interior passed through the various post-offices in the Dutch Indies during the same year. In the same year 1,567,483 letters were carried for foreign postal intercourse. There were 4310 miles of telegraph lines in Dutch India in 1899, with 114 offices; the number of messages was 672,892. In December 1896 Batavia, Samarang, and Surabaya were connected by telephone.

Money and Credit.—The Java Bank, established in 1828, has a capital of 6,000,000 guilders and a reserve of about 1,200,000 guilders. The Government has a control over the administration. Two-fifths of the amount of the notes, assignats, and credits must be covered by specie or bullion. In March 1900 the value of the notes in circulation was 60,591,000 guilders, and of the bank operations 32,623,000. There are two other Dutch banks, besides branches of British banks. In the savings banks, including the postal savings bank, there were in the same year 22,327 depositors, with a deposited amount of £236,499, or £10, 11s. 10d. the credit of each depositor. (H. O. F.; I. P. A. R.)

Recent Political History.—The chief political events in the Malay Archipelago since 1850 have centred in and been dominated by the *Grondwet* or fundamental law of the Netherlands, passed in 1848. For Netherlands India as for Holland it marked the beginning of a new era. It still recognized, it is true, the king as the sovereign of the colonies, but it also introduced for the first time the principle of the Dutch people's responsibilities towards Holland's dependencies in the Far East. It not only laid upon the Crown the obligation of presenting an annual report on the state of the colonies to the States-General, it likewise conferred upon the Dutch legislature the right to fix the colonial budgets periodically, and to settle the bases of colonial government. It was to carry out these new stipulations of the *Grondwet* that Mr Pahud, the Colonial Minister in the cabinet of Dr van Hall, which came into office after the fall of Thorbecke, in 1854 presented a Bill providing for the administration of the Dutch East Indies. That Bill, the so-called *Règlement*, or Government Rules, became law, and has remained in essence, although modified more than once in some of its provisions, the *Grondwet* or constitution of the Dutch colonies. The *Règlement* was virtually a compromise between two extreme parties, one pleading for the long-neglected rights of the natives and against the continuation of the so-called "culture system," involving the *corvée* on Government and seigniorial lands; the other maintaining the principle that the colonies exist to benefit the mother country, and not the mother country to benefit the colonies. The latter party gained the day, and Pahud had to make considerable concessions to get his Bill through. But although the *Règlement* did not answer the expectations and aspirations of the Reform Party, foremost among whom was Baron van Hoëvell, the lifelong and most capable advocate of native rights, yet it was a most important step on the road of progress and administrative reform in the Dutch East Indies. It substituted statutory regulations for administrative and military despotism. It created the Governor-General the *Toean-Begar* ("Great Lord") of the natives, who, although possessing viceregal powers, yet, assisted by an Indian Council, is a functionary responsible for his acts to the Minister for the Colonies at The Hague, and bound to carry out the latter's instructions. It also instituted a supreme court at Batavia, which

controls the whole judicial machinery of Netherlands India, and constitutes the final court of appeal. It abolished slavery in Java, as from 1st January 1860; it introduced freedom of the press up to a certain point, and elementary education for the natives as well. It provided for the leasing of forest lands to Europeans, made a first attempt to settle the *corvée* question on a reasonable basis, and left the door open for future reforms. Of course the *Règlement* was largely an experiment, and where so much depended upon interpretation the results were not, and could not be, always satisfactory, as all the contradictory policies of diverging Ministers for the Colonies in Holland reflected themselves in conflicting edicts of Liberal or anti-Liberal Governors-General at Batavia. It was perhaps in the vexed question of the *heerendiensten* or *corvée* that those vacillating methods of policy were most manifest and most mischievous. But, upon the whole, their tendency, despite repeated setbacks, has been towards the gradual emancipation of the natives both from the thralldom of the "culture system," of which nothing is left but the Government cultivation of coffee, and from the feudal serfdom of their native rulers. That serfdom existed in many forms all over the archipelago, but among the most curious must be reckoned the *pandelingschap* or "pledgedom," which originated in Borneo, and according to which a man had the power to make his debtors temporarily his serfs until their debts were paid, when they resumed their freedom. This abuse, and many other old abuses, have been permanently swept away, and the election of the heads of *dessas* or *kampongs* (districts or villages) by the population has at last become more of a genuine guarantee to the natives than in the post-Raffles days.

Until 1860 the colonial reform movement in Holland had been somewhat erratic, but it then became much more powerful. The chief cause of this change may be traced to the influence exercised by a remarkable book of Douwes Dekker (*q.v.*), *Max Havelaar*, which he published in 1860, with the help of Jan van Lennep, the novelist, then at the height of his literary fame, under the pseudonym of Multatuli ("I bore much"). In Dutch literature this book created a school which still endures; in the political arena it had the effect of a bombshell. The upholders of the old colonial system denied the truth of its allegations, but the friends of reform as violently hailed Douwes Dekker as a "Daniel come to judgment," and denounced the persecutions to which the author had been exposed as a Government official in Java, whilst endeavouring to palliate or uproot the abuses which *Max Havelaar* describes. The most sober-minded party men soon recognized that the palpable exaggerations of the author could not destroy some of his hardest facts, and thus the colonial reform movement made rapid strides in the decade which preceded the death of Thorbecke, who already in 1849, despite Groen van Prinsterer's opposition, had advocated necessary reforms in the Dutch administration of Insulinde, and insisted upon the duties of the motherland towards its colonies.

One of the great names connected with the Indian reform movement in the 'sixties was that of Mr Fransen Van de Putte, who, formerly a so-called "sugar lord" in Java, early in 1863 became Minister for the Colonies in Thorbecke's second ministry. To him the Dutch East Indies owe the annual introduction of a colonial budget, the most important measure concerning the Dutch colonies after the *Règlement*. It for the first time enabled the States-General effectively to control the ways and means of Holland's possessions over-sea, and it must be considered the precursor of the abolition of the *batig slot* or yearly surplus yielded up to the treasury at The Hague

by the Dutch-Indian revenues, although that abolition only came in the year 1876. The same minister, Mr Fransen Van de Putte, in 1865 carried his Bill lessening materially the differentiation of import duties in favour of Dutch goods which existed previously in Netherlands India, whilst Dr Sloet Van de Beele, the then Governor-General at Batavia, introduced various reforms (see JAVA). It is true that his successor, Dr Myer, a reactionary sent out by the Van Zuylen cabinet to reverse Fransen Van de Putte's reform policy, tried to undo a good deal, yet even Dr Myer was compelled to leave many things as he found them, and he was powerless to restore the *corvée* to its former dimensions. In 1870 De Waal, then Minister for the Colonies in a Liberal cabinet, brought about two important colonial reforms. One of the statutes which he passed provided for the restriction of all Government sugar plantations carried on with forced native labour as from 1878, and for their total suppression in 1890, after which year only the Government coffee plantations were to remain, the cultivation of pepper, cochineal, cinnamon, and indigo for Government account having ceased before 1870. The other statute was the so-called Indian Agrarian Law of 1870, which contained many important provisions. It enacted, among other things, that Europeans could lease for 75 years forest lands belonging to the Crown, and that natives could secure proprietary rights in the soil cultivated by them. In 1872 Mr Fransen Van de Putte, once again Colonial Minister in the cabinet which succeeded Thorbecke's last ministry, was able to carry his Bill abolishing all differentiation in a new Dutch-Indian tariff, and establishing a uniform import duty of 6 per cent., with a certain number of free ports all over the Malay Archipelago, rather increasing in latter years than diminishing. That import duty was considered so moderate that, when in 1886 the Dutch-Indian revenues required strengthening, an increase was readily assented to.

These reforms produced the results that had been prognosticated by their advocates. On the one hand, individual enterprise by European capitalists and planters was fostered in the same proportion as the hampering competition of the State was removed. Private plantations and factories arose everywhere, and in 1895 they produced an aggregate of 9,770,000 piculs¹ of sugar, 332,000 piculs of coffee, 3,960,000 kilogrammes of tea, 7,200,000 kilogrammes of tobacco (mainly in Sumatra), 3,570,000 kilogrammes of cinchona bark (grown from Peruvian seedlings by free labour from the beginning in 1852), 475,000 kilogrammes of cacao, and 144,000 kilogrammes of indigo—although it cannot be gainsaid that many of the private planters had a hard struggle, with the low prices ruling for their produce, and a certain number had to succumb. On the other hand, the natives, better protected by the Government against their former oppressors, were undoubtedly benefited to a large extent, as is perhaps best demonstrated by the enormous increase in their numbers. Thus the population of Java and Madura, computed at barely 10,000,000 in 1849, had increased to nearly 27,000,000 by the end of the 19th century.

Dutch power and political authority have immensely grown since 1850, not only in Java (*q.v.*), the principal colony, but also in Sumatra (*q.v.*), Celebes (*q.v.*), where the important districts of Gorontalo have been incorporated (since 1889) with Menado, the residency of the so-called Minahassa, among the earliest and most remarkably successful Dutch settlements in Celebes, the Moluccas (*q.v.*), Borneo (*q.v.*) (where the sultanate of Banjarmassin was added to the Dutch direct dominions in the 'sixties, not, however, until after a protracted warfare, and where

¹ A picul is equal to 133½ lb.

Kootany, on the east coast, formerly a semi-independent state, has since 1897 become a rising and prosperous administrative division of Dutch Borneo), the large islands to the east of Java, and New Guinea (*q.v.*). The fact of course remains that both in Borneo and in New Guinea the Dutch have had to divide their sway with the British or the Germans. Naturally, in the course of time, many armed expeditions had to be sent out to various islands to maintain or extend their political influences and connexions, the most important of such expeditions being those to Acheen and to Lombok in 1894, which ended with the almost complete incorporation of that large island within Holland's colonial dominion. Necessarily the Dutch-Indian army and navy, which are both quite distinct from the army and navy at home, and largely consist of native troops, have had to be materially reinforced from time to time to carry on these distant operations. In the Dutch-Indian army the proportion of Europeans to natives has constantly grown, and the number of European troops (now mostly Dutchmen) has been as high as 16,000 on a total of 40,000 men.

The almost endless and very costly warfare in Acheen had a disastrous bearing upon Dutch-Indian finances, coinciding as it did, at the most critical juncture, with the earnest efforts of the Dutch statesmen in the 'seventies to render Holland financially independent of her colonies, and to make the latter self-supporting. A great portion of such war expenses had to be made good by Dutch-Indian loans, guaranteed by the Dutch Government; yet additional taxation,¹ mainly levied upon the European residents in the Malay Archipelago, had to be resorted to from time to time also, to provide for the large and increasing outlay occasioned by the construction of various important public works. In particular, state railways, commenced in Java by virtue of an Act passed in 1875, but virtually though indirectly inaugurated at a much earlier date, through the medium of state-guaranteed private companies, have since that year been extended to other islands. By these means the revenues of the Dutch-Indian colonies, only 76,000,000 guilders in 1849, had been raised fifty years later to nearly double that amount, whereas expenditure, which was but 53,000,000 guilders in 1849, had almost trebled by the year 1899. War expenses and considerable outlays for public works—among which should be mentioned the improvement of harbours, the subsidizing of steamboat lines between Holland and Java, as well as between Java and the adjacent islands, the construction of vast irrigation works, of roads and telegraphs, by land and by sea—were largely but not altogether accountable for that increased expenditure. Civil administration, police, the administration of justice, last yet not least, education, have all had their much extended claims largely satisfied out of revenue. A great deal has also been done in the way of encouraging arts and sciences, the better study of some remarkable antiquities (Boro Boodoor was officially inspected and described in 1863), the Government support of geological and other surveys, also of various scientific expeditions into the unknown parts of Borneo, Sumatra, Timor, &c.

It has to be noted that coffee alone, among the old Government cultures introduced by Governor-General Van den Bosch, contributed in 1898 some 21,000,000 guilders to the revenue of Netherlands India, the other Government crops having been abolished in succession, after yielding 481,000,000 guilders to the Dutch treasury in the years 1849–66, and 139,000,000 guilders more in the

years 1867–76. Nor was the Government cultivation of coffee in 1898 to be compared to what it had been fifty years before. The area of the Government coffee districts everywhere had been much restricted (in the Minahassa, the northern district of Celebes, referred to above, the Government coffee monopoly was abolished in 1899), and the scope of private coffee-planting correspondingly extended. The native labourers on the Government coffee plantations were, at the end of the 19th century, very much better treated and paid than they had been in 1849, or, for that matter, in 1889. In 1892 a resolution was carried in the second chamber of the Dutch States-General, directing the Minister for the Colonies to do away with the Government growing of coffee, too, but that resolution remained without effect, the Dutch Government then declaring that the revenue from coffee could not yet be spared. On the other hand, the export duty on coffee (and on indigo) was abolished in 1902; this, it was hoped, might help to tide over the difficulties of the private planters.

For literature concerning the recent history of the Malay Archipelago, consult the works mentioned under HOLLAND and JAVA; also the *Aardrijkskundig en Statistisch Woordenboek van Nederlandsch-Indië* ("Geographical and Statistical Dictionary of Netherlands-India"), Amsterdam, 1869, 3 vols.; the *Staatsalmanak van Nederlandsch-Indië* (Government annual publication, published at Batavia), and the *Encyclopædie van Nederlandsch-Indië* ("Encyclopædia of the Dutch East Indies," Leyden and The Hague, 1895, *et. seq.*), the most comprehensive and most authoritative work existing on the subject, but still incomplete, although several volumes have already been issued, to 1902. Its great drawback is the absence of maps and illustrations. (H. T.)

Malay Peninsula (called by the Malays *Tānah Mälāyu*, *i.e.*, the Malay Land), a lozenge-shaped strip of land projecting into the China Sea, and forming the most southerly portion of the continent of Asia. Geographically, the peninsula begins at the isthmus of Kra, 7° 14' N., at which point it is only between 60 and 70 miles in width, and the distance from sea to sea is further diminished by a large irregular salt-water inlet. Politically and anthropologically, however, this upper portion must be regarded as a continuation of the kingdom of Siam rather than as a section of Mälāyu. From the isthmus of Kra the peninsula extends south with a general inclination towards the east, the most southerly point being Tanjong Bûlus in 1° 16½' N. A line drawn diagonally down the centre from the isthmus of Kra to Cape Romania (Ramûnya) gives the extreme length at about 510 miles. The breadth at the widest point, from Tanjong Pën-ânjut in Trënggānu to Tanjong Hantu in the Dindings territory, is about 200 miles. The area is estimated at about 70,000 square miles. The peninsula is bounded on the north by Siam, on the south by the island and strait of Singapore, on the east by the China Sea, and on the west by the strait of Malacca.

A range of granite mountains stretching from the eastern shoulder in 6° 40' N. to the west coast in 2° 25' N., irregularly following the parallel 101° 40' E., forms a backbone which divides the peninsula into two unequal portions, the larger of which lies to the east and the smaller to the west of the chain. Smaller ranges run parallel to the main mountain chain in many places, and there are numerous isolated spurs which have no connexion with either. The country is covered with limestone in many parts, and large isolated bluffs of this formation stand up in the plains both on the eastern and the western slopes. The descent from the summits of the range into the plain is somewhat less abrupt on the western than it is on the eastern side, and between the foot of the mountains and the strait of Malacca the largest known alluvial deposits of tin are situated. On the eastern side of the range, after a steep descent, the granite formation speedily gives place to slates of vast depth, intersected here and there by fissures of quartz containing gold, and in many places covered by limestone which has been superimposed upon the slates. The highest known peak in the main range is that of Gûngong Korbu, 7217 feet above sea-level. The highest mountain is believed to be Gûngong Tāhan, which forms part of an isolated

Physical characteristics.

¹ It includes, since 1898, a tax on petroleum, now found in large quantities in Java, Sumatra, and elsewhere; likewise an import duty on foreign matches. Both yield an increasing revenue.

range on the eastern side, between Pahang and Kélanan, and is estimated at about 8000 feet. The west coast throughout its whole length is covered to a depth of some miles with mangrove swamps, with only a few isolated stretches of sandy beach, the dim foliage of the mangroves and the hideous mud flats presenting a depressing spectacle. On the east coast the force of the north-east monsoon, which beats upon the shores of the China Sea annually from November to February, has kept the land for the most part free from mangroves, and the sands, broken here and there by rocky headlands thickly wooded, and fringed by *casuarina* trees, stretch for miles without interruption. The islands on each coast present the features of the shores to which they are adjacent. On both the east and the west coast the islands are thickly wooded, but whereas the former are surrounded by beautiful sands and beaches, the latter are fringed by mangrove swamps. The whole peninsula may be described as one vast forest, intersected in every direction by countless streams and rivers which together form the most lavish water-system in the world. Only an insignificant fraction of these forests has ever been visited by human beings, the Malays and even the aboriginal tribe having their homes on the banks of the rivers, and never, even when travelling from one part of the country to another, leaving the banks of a stream except for a short time when passing from one river-system to another. The bulk of the jungle, therefore, which lies between stream and stream, has never been trodden by the foot of man. The principal rivers on the west coast are the Pérak, the Bérnam, and the Mûar. The first-named is far finer than its fellows, and is navigable for steamers for about 40 miles from its mouth, and for native craft for over 250 miles. It is exceedingly shallow, however, and is not of much importance as a waterway. The Bérnam runs through flat swampy country for the greater part of its course, and steam-launches can penetrate to a distance of over 100 miles from its mouth, and it is therefore probably the deepest river. The country which it waters, however, is not of any value, and it is not much used. The Mûar waters a very fertile valley, and is navigable for native boats for over 150 miles. On the east coast the principal streams are the Pétani, Têlûbin, Kélanan, Bésut, Trênggânû, Dângun, Kémâman, Kuantan, Pahang, Rompin, Endau, and Sédéli, all guarded by difficult bars at their mouths, and dangerous during the continuance of the north-east monsoon. The deepest rivers are the Kuantan and Rompin; the largest are the Kélanan and the Pahang, both of which are navigable for native boats for a distance of over 250 miles. The Trênggânû river is obstructed by impassable rapids at a distance of about 30 miles from its mouth. The rivers on the east coast are practically the only highways, the Malays always travelling by boat in preference to walking, but they serve their purpose very indifferently, and their great beauty is their chief claim to distinction. Magnificent caves are found on both slopes of the peninsula, those at Bâtu in Sêlângor being the finest on the west coast, while those of Châdu and Kôto Glangi in Pahang are the most extensive yet visited by Europeans on the east coast. They are all of limestone formation. The minerals produced are tin, gold, iron, galena, and others in insignificant quantities. Only two tin lodes are being worked, however, and both are situated on the east coast, the one at Kuantan in Pahang, the other at Bandi in Trênggânû territory. On the west coast no true lode has yet been discovered, though the vast alluvial deposits of tin found there seem to make such a discovery probable in the future. Since 1890 the tin produced from these alluvial beds has supplied between 50 and 75 per cent. of the tin of the world. Gold is being worked with success in Pahang, and has been exploited from time immemorial by the natives of that state and of Kélanan. Small quantities have also been found on the western slope in Pérak.

It was formerly the custom to speak of the Malay Peninsula as an unhealthy climate, and even to compare it with the west coast of Africa. It is now generally admitted, however, that though hot, it compares favourably with that of Burma. The chief complaint which Europeans make concerning it is the extreme humidity, which causes the heat to be more oppressive than is the case where the air is dry. On the other hand, the thermometer, even at Singapore on the southern coast, which is the hottest portion of the peninsula, seldom rises above 98° in the shade, whereas the mean for the year at that place is generally below 80°. On the mainland, and more especially on the eastern slope, the temperature is cooler, the thermometer seldom rising above 93° in the shade, and falling at night below 70°. On an average day in this part of the peninsula the temperature in a European house ranged from 88° to 68°. The number of rainy days throughout the peninsula varies from 160 to over 200 in each year, but violent gusts of wind, called "Sumatras," accompanied by a heavy downpour of short duration, are more common than persistent rain. The rainfall on the west coast varies from 75 to 120 inches per annum, and that of the east coast, where the north-east monsoon breaks with all its fury, is usually about 155 inches per annum. Malarial fevers make their appearance in places where the forest has been recently felled, or where the surface earth has been disturbed. It is noticed that labourers employed in deep mines worked

by shafts suffer less from fever than do those who are engaged in stripping the alluvial deposits. This, of course, means that a new station, where clearing, digging, and building are in progress, is often unhealthy for a time, and to this must be attributed the evil reputation which the peninsula formerly enjoyed. To Europeans the climate is found to be relaxing and enervating, but if, in spite of some disinclination for exertion, regular exercise is taken from the beginning, and ordinary precautions against chills, more especially to the stomach, are adopted, a European has almost as good a chance of remaining in good health in the peninsula as in Europe. A change of climate, however, is imperatively necessary every five or six years, and the children of European parents should not be kept in the peninsula after they have attained the age of four or five years. The Chinese immigrants suffer chiefly from fever of a malarial type, from beri-beri, a species of tropical dropsy, and from dysentery. The Malays formerly suffered severely from smallpox epidemics, but in the portion of the peninsula under British rule vaccination has been introduced, and the ravages of the disease no longer assume serious dimensions. Occasional outbreaks of cholera occur from time to time, and in the independent states these cause terrible loss of life, as the natives fly from the disease and spread the infection in every direction. As a whole, the Malays are, however, a remarkably healthy people, and deformity and hereditary disease are rare among them. There is little leprosy in the peninsula, but there is a leper hospital near Penang on Pûla Dêrâja, and another is about to be formed on an island on the west coast for the reception of lepers from the Federated Malay States.

The soil of the peninsula is remarkably fertile both in the plains and on the mountain slopes. In the vast forests the decay of vegetable matter during countless ages has enriched the soil to the depth of many feet, and from it springs the most marvellous tangle of huge trees, shrubs, bushes, underwood, creepers, climbing plants, and trailing vines, the whole hung with ferns, mosses, and parasitic growths, and bound together by rattans and huge rope-like trailers. In most places the jungle is so dense that it is impossible to force a way through it without the aid of a wood-knife, and even the wild beasts use well-worn game-tracks through the forest. In the interior brakes of bamboos are found, many of which spread for miles along the river banks. Good hard-wood timber is found in plenty, the best being the *mêrâbau*, *pênak*, *rasok*, and *chêngal*. Orchids of countless varieties abound. The principal fruit trees are the *dûri-an*, mangosteen, custard-apple, pomegranate, *rambut-an*, *pûlas-an*, *langsat*, *rambai*, jack-fruit, cocoanut, areca nut, sugar-palm, and banana. Coffee, tobacco, sugar-cane, rice, pepper, gambier, cotton, and sago are cultivated with success. The principal jungle products are gutta and rubber of several varieties, and many kinds of rattan. The mangrove grows on the shores of the west coast in profusion. Agila-wood, the camphor tree, and ebony are also found in smaller quantities.

The fauna of the peninsula is varied and no less profuse than is the vegetable life. The Asiatic elephant; the *sêlândang*, a bison of a larger type than the Indian gaur; two varieties of rhinoceros; the honey bear (*brûang*), the sambhur (*rûsa*); the speckled deer (*kûiang*), three varieties of mouse-deer (*nâpoh*, *plândok*, and *kanchil*); the gibbon (*ûngka* or *wava*), the *siamang*, another species of anthropoid ape, the *brok* or cocoanut monkey, so called because it is trained by the Malays to gather the nuts from the cocoanut trees, the *lôtong*, *kra*, and at least twenty other kinds of monkey; the *bintûrong* (*arctictis bintûrong*), the lemur; the Asiatic tiger, the black panther, the leopard, the large wild cat (*harîmau âkar*), several varieties of jungle cat; the wild boar, the wild dog; the flying squirrel, the flying fox; the python, the cobra, and many other varieties of snake, including the hamadryad; the alligator, the otter, and the gavia, as well as countless kinds of squirrel, rat, &c., are found throughout the jungles of the peninsula in great numbers. On the east coast peafowl are found, and throughout the interior the argus pheasant, the firebacked pheasant, the blue partridge, the adjutant-bird, several kinds of heron and crane, duck, teal, cotton-teal, snipe, wood-pigeon, green-pigeon of several varieties, swifts, swallows, pied-robins, hornbills, paroquets, flycatchers, nightjars, and many other kinds of bird are met with frequently. A few specimens of solitary goose have been procured, but the bird is rarely met with. The forests literally swarm with insects of all kinds, from *cicada* to beautiful butterflies, and from stick- and leaf-insects to endless varieties of ants. The scorpion and the centipede are both common. The study of the insect life of the peninsula opens a splendid field for scientific research, and the profusion and variety of insects found in these forests probably exceed those to be met with anywhere else in the world.

Politically the Malay Peninsula is divided into three sections:— 1. The Federated Malay States; 2. The Independent State of Johor, which is within the British sphere of influence; 3. The Independent States of the Peninsula which are actually or nominally under the dominion of Siam. The Federated Malay States, under British protection, are four in number, viz., Pérak, Sêlângor, and the Nêgri Sêmbilan on the west coast, and Pahang on the east coast.

Flora and fauna.

Political divisions and population.

Johor is the only Malay state in the portion of the peninsula lying within the British sphere of influence which has been allowed to remain under native rule.

The Malay states which either nominally or actually are under the dominion of Siam are as follows:—Palëan, Sätun, Pälit, and Këdah on the west coast; Pëtäni, Jëring, Sai, Lëgeh, Këlantän, and Trënggänu on the east coast; and Jälör and Râman inland. The aggregate area of these states is roughly estimated at about 20,000 square miles, and the population, chiefly Malayan, may be placed at about 200,000. Once in three years the rulers of these states send tribute to Siam in the form of flowers fashioned from gold and silver (*bûnga âmas*), and presents from the king at Bangkok of approximately the same value are returned by the messengers who bear the tribute.

Këdah is situated on the west coast of the Malay Peninsula, between parallels 5° 2' and 6° 42' N. The coast-line is only about 66 miles long, and the greatest distance from north to south is about 115 miles, and the greatest breadth at the widest point is about 47 miles. The area may be estimated at about 6000 square miles, and the population, 75 per cent. of whom are Malays, at about 45,000. According to the native tradition, Këdah was at one time a tributary of Malacca, and was subsequently conquered by the Acheenese. Later, the natives of Këdah invaded and conquered Përak, but they eventually withdrew. In the middle of the 18th century, if not earlier, Këdah fell under the dominion of Siam, and has continued from that time to send the *bûnga âmas* (tribute) to Bangkok every three years. Until recently this tribute seems to have formed the only right exercised by Siam with regard to her Malayan dependencies, and it is open to question whether this gift did not partake of the nature of a conciliatory present to a powerful neighbour rather than of that of a direct admission of sovereignty. Be this how it may, it is certain that the cession of Penang to the East India Company in 1785 and of Province Wellesley in 1798 was granted by the then sultan of Këdah without the approval of Siam being sought or given. Of late years, however, spurred thereto by the growing influence of the British in the Malay Peninsula, Siam has been at great pains to tighten her hold over the Malayan states which have for so long been nominally under her dominion, and in no part of the peninsula has this been done to greater effect than in Këdah. The sultan of that state, nominated and installed by the king of Siam, and granted a Siamese title, is now no better than a governor appointed by Siam to rule the state which is his birthright, and during the visit of the king to the peninsula, in 1890, the sultan was forced to follow his suzerain about as one of the least considered of his nobles. The state is not much better governed than other Malayan countries which are not under European management, the Siamese concerning themselves but little with the details of administration, and displaying in their own land the deplorable lack of political purity and love of justice which seemingly are flaws from which no Oriental government has the power to free itself. A little alluvial tin is worked in Këdah, but the chief products are agricultural, the Malays of this state growing a considerable quantity of rice with some success.

Palëan, *Sätun*, and *Pälit* are three small states on the west coast, lying to the north of Këdah. Like Sënggöra on the east coast, they form part of Lower Siam, and can hardly be regarded as an integral portion of the Malayan Peninsula. They are not of any political or commercial importance, and are under the rule of the Siamese governor of Junkseylon. The resident councillor of Penang for the time being is the consul-general for Këdah and for these Siamese states on the west coast.

Pëtäni is the name properly applied to a small state situated on the north-east shoulder of the Malay Peninsula, but it is usually employed to include the small states of Jëring, Sai, Jälör, and Râman also. Each of these little states, however, is under its own Malay ruler, and all are directly under the influence and control of Siam. Speaking of Pëtäni in the wider application of the name, it may be said to be bounded by the China Sea on the N. and E., by Përak and Lëgeh on the S., and by Këdah on the W. It is situated between 5° 34' and 6° 52' N. and 100° 54' and 101° 58' E. Its total area is about 4000 square miles. A portion of Râman is claimed by Përak, and has formed the subject

of dispute since 1882. The population, which is unusually thick for the peninsula, is estimated at about 20,000, of whom about 6000 are Chinese and Siamese. Pëtäni is historically important as having been the scene of the first factory established by the East India Company in the peninsula. Pëtäni is also remarkable as having for an extended period of time been governed by a Malay queen, the only recorded instance of female government in the history of the peninsula. To-day Pëtäni, under the rule of Siam, is a place of little importance. Its native räjäs exert little influence over their people, and the petty jealousies which exist between the rulers of the various tiny states give rise to constant quarrels between them and their adherents. The natives of Pëtäni are skilled in the art of catching and taming elephants.

The chief industry of the country along the coast is the evaporation of salt from sea-water.

Këlantän is the name of a large native state on the east coast of the peninsula. It is bounded on the N. and N.E. by the China Sea, on the S. by Pahang, on the E. by Trënggänu, and on the W. by Përak. It lies between parallels 4° 48' and 6° 20' N. and 101° 33' and 102° 45' E. The greatest distance from north-east to south-west is 108 miles, and the greatest breadth from east to west is 68 miles. The total area of the state is about 7000 square miles. Next to the Pahang, the Këlantän river is the largest on the east coast. It is shallow, and the upper reaches are somewhat obstructed by rapids, but it is navigable for native trading boats for a distance of nearly 200 miles. Its principal tributaries are Gälas, Nënggiri, Përgai, and Lëbir rivers. The Gälas valley is rich in alluvial gold, and there is every reason to believe that lodes also exist. A Chinese colony, chiefly composed of Ho-Kien and Te-Chow Chinese, has existed at Pülai in this valley from time immemorial, the original founders of the settlement having been attracted thither by gold mines. The community is ruled by a Kapitan China, appointed by the sultan. The Lëbir valley is almost entirely peopled by fugitives from Pahang, who sought refuge from the constant civil wars which raged in that state. The Nënggiri valley is largely peopled by aborigines, men of the Mon-Annam stock, who from time to time have carried on a desultory warfare with the Malays. The Përgai is also rich in gold, and forms the principal highway into the state of Lëgeh.

Këlantän is nominally under the control of Siam, and since the death in 1889 of the old sultan, Mülüt Mërah (The Red-Mouthed), who for more than sixty years ruled the country with great force and cruelty, the strife for the throne which has been carried on by his grandchildren has led to each pretender seeking to strengthen his individual position by enlisting the sympathies of Siam. This has enabled the king to obtain a more definite hold over the country than was possible during the reign of Mülüt Mërah, and in 1892 an issue of postage stamps was put in circulation in Këlantän bearing the portrait of the king of Siam, and a Malay, born in Bangkok, was sent to Kôta Bharu, the capital of the state, to act as post-master and Siamese representative. Since that time the influence of Siam in Këlantän has steadily increased, and now the flag of the white elephant floats at the mouth of the river.

The country in the vicinity of the capital is more open than is usual in the Malayan lands. Broad stretches of grazing-ground are found, and the breed of cattle and sheep which thrives there is the best in the peninsula. Considerable quantities of live stock are exported to Singapore. The whole of the state is very fertile, and the natives, who physically are of a somewhat larger type than most Malays, are more hardworking than those of any other state in the peninsula. Since Pahang was placed under British protection, and the lives of immigrants were rendered safe thereby, a large number of Këlantän Malays have made their way into that country, and people of that tribe now supply 70 per cent. of the Malay labour there obtainable. As compared with other Malay states, Këlantän has always enjoyed the reputation of being exceedingly populous, and even now, when the population has been diminished by cholera, smallpox, and emigration, it can safely be estimated at 75,000 souls. A round tin coin, with a hole in the centre, like a Chinese "cash," is issued by the sultan, and the old pillar dollar is the standard coin, Mexican dollars being reckoned as being less valuable by one-third. Until quite recently the latter were received with the utmost reluctance. The ruling family of Këlantän belongs to a clan bearing the title of *Wan*, and is not regarded by other Malay ruling families as belonging to any royal stock. The title of sultan was assumed only about 1885 for the first time. Këlantän, if well governed, would probably be one of the most prosperous states in the peninsula, but under native rule all manner of abuses exist, which cannot but discourage commerce and immigration. The natives of Këlantän are addicted to prize-fighting, and also keep rams and buffalo-bulls for similar purposes.

Trënggänu is the name of a large state on the east coast of the peninsula. It is bounded on the N.E. and E. by the China Sea, on the S. by Pahang, and on the W. by Këlantän and Pahang. It lies between parallels 4° 4' and 4° 46' N. and 102° 30' and 103° 26' E. The greatest distance from north to south is 120 miles; the greatest breadth from east to west is 50 miles. It has a coast-line 130 miles in length, and the estimated area of the state is about 6000 square miles. The principal rivers of the state are the Bësut, Stiu, Trënggänu, Dûngun, and Këmâman, each of which waters a district of some importance, the revenues of which are drawn by one or another of the sultan's many relatives. The sultan himself derives his revenues from the district lying immediately around his capital at Kuäla Trënggänu, but these represent so small a proportion of the revenues of the state that he is probably the poorest ruler in the peninsula. The Bësut district is inhabited entirely by Malays, and was reduced by a war conducted about 1875 by Bäginda Umar, the grandfather of the present (1902) sultan. It is chiefly remarkable as

having suffered more than any other district on the coast from a typhoon which raged during 1882 and felled the forest for miles. Later the dead timber generated fire, and for some miles inland the traces of this double calamity are still visible. The Stiu river is a long, muddy, and very deep inlet, and is chiefly famous for the number and boldness of the alligators which infest it. The Trénggānu district is very thickly inhabited for the first 30 miles of the river's course from its mouth to the impassable falls known as Lāta Kĕlĕmang. Above this point the population only numbers about 500 souls, the falls, which are 5 miles long, presenting a barrier to trade which has effectually prevented the development of the rich interior. Even above the falls the river is difficult, owing to the size of the rapids with which it is beset, and the Trénggānu proper, above the point where it is joined by the Kĕrbat, is quite impassable for boats of any kind. The consequence of this is that the whole population of the Trénggānu valley is concentrated within the narrow strip of country lying between the sea and the Kĕlĕmang Falls, and almost every inch of the country is cultivated with a thoroughness which is unlike anything to be seen anywhere else in the peninsula. The Dŭngun takes its rise in the hills, whence the Tĕmbĕling river flows into Pahang. It is noted for the amount of gutta which is annually exported from the valley. The Kĕmātan river waters a valley bordering on Kuantan in Pahang territory, and has the reputation of being rich in tin. A lode is being worked by a European company at Bandi in this district. The people of Trénggānu, owing to the enlightened policy of the late Bāginda Umar, who introduced skilled artisans to teach his people, are the best workers in metal and wood on the coast. They build excellent boats of a European type, weave all manner of native silks and cotton stuffs, make weapons and brass and nickel ware, and are especially famous for their skill in producing spurious articles which so closely resemble the originals that detection is well-nigh impossible.

The Trénggānu sultanate is one of the most ancient in the peninsula, and ranks with that of Riau. The country was conquered by Bāginda Umar in 1837, the then sultan, the son of the conqueror's elder brother, subsequently dying while flying from his uncle. The present sultan is the grandson of the Bāginda. He is very religiously inclined, and the people of this state are more fanatical Mahommedans than are to be found elsewhere in the peninsula.

Lĕgeh is the name of a small state which is more directly under the rule of Siam than Kĕlantān. It is said to contain gold in payable quantities. It is not of much political importance. Its area is about 2000 square miles.

Excluding the Tai, or Siamese, who are undoubtedly recent intruders from the north, there are three races which for an extended period of time have had their home in the Malay Peninsula. These are the Sĕmang or Pangan, the Sākai or Jākun, and the Malays. The Sĕmang, as they are most usually called by the Malays, are Negritos—a small, very dark people, with features of the negro type, very prognathous, and with short, woolly hair clinging to the scalp in tiny crisp curls. These people belong to the race which would seem to be the true aboriginal stock of southern Asia. Representatives of it are found scattered about the islands from the Andaman group southwards. The state of civilization to which they have attained is very low. They neither plant nor have they any manufactures except their rude bamboo and rattan vessels, and the bows, blow-pipes, and bamboo spears with which they are armed. They are skilful hunters, however, catch fish by ingeniously-constructed traps, and live almost entirely on jungle-roots and the produce of their hunting and fishing. The most civilized tribe of these people is found in Upper Pĕrak, and the members of this clan have acquired some knowledge of the art of planting, &c. They cannot, however, be taken as typical of their race, and other specimens of this people are seldom seen even by the Sākai. From time to time they have been raided by the latter, and many Negritos are to be found in captivity in some of the Malayan villages on the eastern side of the peninsula. The mistake of speaking of the Sākai tribes as practically identical with the Sĕmang or Pangan has very frequently been made, but as a matter of fact the two races are absolutely distinct from one another. It has also been customary to include the Sākai in the category of Malayan races, but this too is undoubtedly incorrect. The Sākai still inhabit in greatest numbers the country which forms the interior of Pahang, the Plus and Kinta districts of Pĕrak, and the valley of Nĕnggiri in Kĕlantān. Representatives of their race are also found scattered among the Malayan villages throughout the country, and also along the coast, but these have intermixed so much with the Malays, and have acquired so many customs, &c., from their more civilized neighbours, that they can no longer be regarded as typical of the race to which they belong. The pure Sākai in the interior have a good knowledge of planting rice, tapioca, &c., fashion pretty vessels from bamboos, which they decorate with patterns traced by the aid of fire, make loin-cloths (their only garment) from the bark of the *trap* and *ipoh* trees; are very musical, using a rude lute of bamboo, and a nose-flute of a

very sweet tone, and singing in chorus very melodiously; and altogether have attained in their primitive state to a higher degree of civilization than have the Sĕmang. They are about as tall as the average Malay, are slimly built, light of colour, and have wavy fine hair. In their own language they have only three numerals, viz., *na-nun*, one; *na'*, two; and *ne'*, three; all higher arithmetical ideas being expressed by the word *kĕrpn*, which means "many." Among the more civilized, however, the Malay numerals up to ten are adopted by the Sākai. An examination of their language seems to indicate that it belongs to the Mon-Annam family of languages, and the anthropological information forthcoming concerning the Sākai points to the conclusion that they show a greater affinity to the people of the Mon-Annam family of races than to the Malayan stock. Though they now use metal tools imported by the Malays, it is noticeable that the names which they give to those weapons which most closely resemble in character the stone implements which are found in such numbers all over the peninsula are native names wholly unconnected with their Malay equivalents. On account of this, it has been suggested that in a forgotten past the Sākai were themselves the fashioners of the stone implements, and certain it is that all tools which have no representatives among the stone kelts are known to the Sākai by obvious corruptions of their Malayan names. The presence of the Sākai, a people of the Mon-Annam stock, in the interior of the peninsula has also been considered as one of many proofs that the Malays intruded from the south, since had they swept down from the north, being driven thence by the people of a stronger breed, it might be expected that the fringe of country dividing the two contending races would be inhabited by men of the more feeble stock. Instead, we find the Sākai occupying this position, thus indicating that they have been driven northwards by the Malays, and that the latter people has not been expelled by the Mon-Annam races from the countries now represented by Burma, Siam, and French Indo-China. The Sākai population is dying out, and must eventually disappear. (With regard to the Malay, see MALAYS.)

The only ancient remains found in the peninsula are the stone implements, of which mention has already been made, and some remarkable ancient mines, which are situated in the Jĕlai valley in Pahang. The stone implements are generally of one or two types: a long rectangular adze or wedge rudely pointed at one end, and used in conjunction with a mallet or flat stone, and a roughly triangular axe-head, which has evidently been fixed in the cleft of a split stick. A few stones, which might perhaps be arrow-heads, have been found, but they are very rare.

The mines, which have been constructed for the purpose of working quartz lodes containing gold, are very extensive, and argue a high stage of civilization possessed by the ancient miners. They consist of a number of circular or rectangular pits sunk from the cap of a hill, and going down to a depth of in some cases as much as 120 feet, until in fact the miners have been stopped by being unable to cope with the quantity of water made when the level of the valley was reached. The shafts are placed so close together that in many instances they are divided by only a couple of feet of solid ground, but at their bases a considerable amount of gallery work has been excavated, though it is possible that this was done by miners who came after the people who originally sank the shafts. Native tradition attributes these mines to the Siamese, but not much importance can be attached to this, as it is very general for the Malays to give this explanation for anything which is obviously not the work of their own ancestors. A theory, which seems to have some probability in its favour, is that these mines were worked by natives of India during the period when the whole of the Malayan Archipelago was more or less overrun by the Hindu races, but the absence of all remains which might aid in the identification of the ancient miners renders it impossible at the present time to give any authoritative opinion on this point.

The Malay Peninsula was known to the ancients as the *Aurea Chersonesus*, and there can be no doubt that from a very early time a constant trade was maintained between the people of the peninsula and archipelago and the natives of Arabia, Persia, and India. Cloves, nutmegs, and other spices are believed to have formed the chief articles of commerce, and to have come almost entirely from Malayan lands, reaching Europe *via* Arabia. At one period in its history the archipelago was overrun by Hindus from India, and traces of their presence are found to this day in Java and other islands of the archipelago, the people of Bali, for instance, still professing a kind of Hinduism. There is no evidence to show, however, that the influence of the Hindus ever extended to the peninsula itself. The wave of Mahommedanism which later swept over the peninsula and archipelago was a peaceful, not a warlike invasion. The first Mahommedan missionaries were the traders who, following in the steps of their forebears, acted as the middle-men by whose agency the trade of the East Indies found its way into Europe. The rāja of Acheen in Sumatra was the first convert of note. He publicly embraced the new creed

Races of the peninsula.

History.

in 1206. The sultan of Malacca became a Mahomedan in 1276, but it is probable that long before that date the faith of the Prophet had won a sure foothold among the Malays of his kingdom and of the west coast generally. Vasco da Gama rounded the Cape of Good Hope in 1496, but the peninsula itself does not appear to have been visited until the time of Magellan. Malacca was visited by the Portuguese Sequeira in 1509, and was conquered by Albuquerque in 1511, this being the earliest European settlement on the mainland of the peninsula. Drake was the first Englishman to make a journey to the Malayan Archipelago, coming from the east of the Moluccas, and calling at Bantam in 1578. Ten years later Cavendish followed the same route. In 1592 Lancaster left Zanzibar in February and called at Penang ("Pulo Pinaom"), where he remained till the end of August. This was the first British trading expedition to the East Indies. The Dutch under Houtman visited Bantam in 1595-96. In 1600 the East India Company was formed in London, principally for the purpose of trading with Malaya, and the first fleet belonging to the company was sent out under Lancaster's command in 1601. During Captain Hippon's voyage in 1612-13 the peninsula was first rounded by a British ship, and in the latter year a factory was established in Pētāni, and the first president, Captain Jourdain, was killed in 1620 in a naval engagement with the Dutch in Pētāni Roads. It was in the course of various voyages to Malaya that attention was first attracted by the mainland of India, and the commerce which had progressed favourably in Malayan waters ultimately led to the establishment of the Indian Empire. Malacca was wrested from the Portuguese by the Dutch in 1641. The principal stations of the East India Company in Malayan lands were on the island of Sumatra, and it was not until 1795 that Malacca was taken by the British from the Dutch. It was restored to the Dutch by the treaty of 1818, and it did not come finally into British hands until 1824, when it was exchanged for Bencoolen in Sumatra. Penang was purchased from Kédah in 1786, and Singapore from the then sultan of Johor in 1819. The native state of Pérak was placed under British protection in 1874, and between that date and 1888 the other native states which now form the federation were also placed under protection. The Straits Settlements were ruled from India until 1867, when they became a Crown colony.

(H. CL.)

Malays, the name given by Europeans to the people calling themselves *Órang Máláyu*, i.e., Malayan folk, who are the dominant race of the Malay Peninsula and of the Eastern Archipelago. Broadly speaking, all the brown races which inhabit the portion of Asia south of Siam and Indo-China, and the islands from the Philippines to Java, and from Sumatra to Timor, may be described as belonging to the Malayan family, if the aboriginal tribes, such as the Sákai and Sémang in the Malay Peninsula, the Bâtaks in Sumatra, and the Mútruts in Borneo, be excepted. For the purposes of this article, however, only those among these races which bear the name of Órang Máláyu, speak the Malayan language, and represent the dominant people of the land, can be included under the title of Malays. These people inhabit the whole of the Malayan Peninsula to the borders of Lower Siam, the islands in the vicinity of the mainland, the shores of Sumatra and some portions of the interior of that island, Sarâwak and Brúnei in Borneo, and some parts of Dutch Borneo, Batavia, and certain districts in Java, and some of the smaller islands of the archipelago. Though in these lands they have for not less than a thousand years enjoyed the position of the dominant race, they all possess a tradition that they are not indigenous, and that their first rulers "came out of the sea," with a large band of Malayan warriors in their train. In the peninsula especially, where the presence of the Malays is more recent than elsewhere, many traditions exist which point to a comparatively recent occupation of the country. It has been remarked that there is evidence that the Malays had attained to a certain stage of civilization before ever they set foot in Malaya. For instance, the names which they give to certain fruits, such as the *dûri-an*, the

rambut-an, and the *pûlas-an*, which are indigenous in the Malayan countries, and are not found elsewhere, are all compound words meaning respectively the thorny, the hairy, and the twisted fruit. These words are formed by the addition of the substantial affix "*-an*," the use of which is one of the recognized methods by which the Malays turn primitive words into terms of more complex meaning. This may be taken to indicate that when first the Malays became acquainted with the fruits which are indigenous in Malayan lands, they already possessed a language in which most primary words were represented, and also that their tongue had attained to a stage of development which provided for the formation of compound words by a system sanctioned by custom and the same linguistic instinct which causes a Malay to-day to form similar compounds from European and other foreign roots. For any aboriginal race inhabiting these countries, such important articles of diet as the *dûri-an*, &c., could not fail to be among the first natural objects to receive a name, and thus we find primary terms in use among the Sákai and Sémang, the aborigines of the Peninsula, to describe these fruits. The use by the Malays of artificially constructed terms to denote these things may certainly be taken to strengthen the opinion that the Malays arrived in the lands they now inhabit at a comparatively late period in their history, and at a time when they had developed considerably from the original state of primitive man.

Until recently many eminent scientists held the theory that the Malayan peoples were merely an offspring of the Mongol stock, and that their advance into the lands they now inhabit had taken place from the cradle of the Mongolian race—that is to say, from the north. In the fifth edition of his *Malay Archipelago*, p. 591, A. R. Wallace notes the resemblance which he traced between the Malays and the Mongolians, and others have recorded similar observations as to the physical appearance of the two races. To-day, however, fuller data are available than when Wallace wrote, and the more generally accepted theory is that the Malayan race is distinct, and came from the south, until it was stayed by the Mongolian races living on the mainland of southern Asia. The cranial measurements of the Malays and an examination of their hair sections seem to bear out the theory that they are distinct from the Mongolian races. Their language, which is neither monosyllabic nor tonic, has nothing in common with that of the Mon-Annam group. It has, moreover, been pointed out that had the Malays been driven southwards by the stronger races of the mainland of Asia, it might be expected that the peoples inhabiting the country nearest to the border between Siam and Malaya would belong to the Malayan and not to the Mon-Annam stock. As a matter of fact the Sákai of the interior of the peninsula belong to the latter race. It might also be anticipated, were the theory of a southward immigration to be sustained, that the Malays would be newcomers in the islands of the archipelago, and have their oldest settlements on the Malayan Peninsula. The facts, however, are in exact contradiction to this; and accordingly the theory now most generally held by those who have studied the question is that the Malays form a distinct race, and had their original home in the south. Where this home lay it is not easy to say, but the facts recorded by many writers as to the resemblance between the Polynesian and the Malayan races, and the strong Malayan element found in the languages of the former (see Tregear's *Maori and Comparative Polynesian Dictionary*, London, 1891), have led some students to think that the two races may have had a common origin. John Crawford, in the Dissertation to his *Dictionary of the Malay Language*, published in 1840, noted the prevalence of Malayan terms

Theories of origin.

in the Polynesian languages, and attributed the fact to the casting away of ships manned by Malays upon the islands of the Polynesian Archipelago. The appearance of the same Malayan words in localities so widely separated from each other, however, cannot be satisfactorily accounted for by any such explanation, and the theory is now more generally held that though the two races are ethnologically distinct, they may, at some remote period of history, have shared a common home. It has been suggested that their separation did not take place until after the continent which once existed in the north Pacific had become submerged, and that the Malays wandered northwards, while the Polynesian race spread itself over the islands of the southern archipelago. All this, however, must necessarily be of the nature of the purest speculation, and the only facts which we are able to deduce in the present state of our knowledge of the subject may be summed up as follows: (a) That the Malays ethnologically belong to a distinct race; (b) that the theory formerly current, to the effect that the Sâkai, Órang Bêñúa, Órang Laut, and other similar races of the peninsula and archipelago belonged to the Malayan stock, cannot be maintained, since recent investigations tend to identify them with the Mon-Annam family of races; (c) that the Malays are, comparatively speaking, newcomers in the lands which they now inhabit; (d) that it is almost certain that their emigration took place from the south; (e) and that, at some remote period of their history, they came into close contact with the Polynesian race, probably before its dispersion over the extensive area which it now occupies.

The Malays to-day are Sunni Mahomedans of the school of Shafi'i, and they habitually use the terms *Órang Máláyu*, i. e., a Malay, and *Órang Islâm*, i. e., a Mahomedan, as synonymous expressions. Their conversion from paganism took place during the 13th, 14th, and 15th centuries of our era, the earliest recorded conversion of a Malay ruler being that of the Râja of Acheen in northern Sumatra in 1206, and the latest that of the Bûgis people of Celebes in 1495. The sultan of Malacca, whose conversion occurred in 1276, was the first ruler of the peninsula to embrace the Mahomedan religion. Upon the bulk of the Malayan peoples their religion sits but lightly. Few are found to observe the law concerning the Five Hours of Prayer, and many fail to put in an appearance at the Friday congregational services in the mosques. The Fast of Ramathân, however, is generally observed with some faithfulness. Compared with other Mahomedan peoples, the Malays are not fanatical, though occasionally an outbreak against those of a different creed is glorified by them into a holy war. The reason of such outbreaks, however, is usually to be found in political and social rather than in religious grievances. Prior to their conversion to Mahomedanism, the Malays were subjected to a considerable Hindu influence which reached them by means of the traders who visited the archipelago from India. In the islands of Bâli and Lômbock the people still profess a form of Hinduism, and Hindu remains are to be found in many other parts of the archipelago, though their traces do not extend to the peninsula. Throughout, however, the superstitions of the Malays show indications of this Hindu influence, and many of the demons whom their medicine-men invoke in their magic practices are clearly borrowed from the pantheon of India. For the rest, a substratum of superstitious beliefs which survives from the days when the Malays professed only their natural religion is to be found firmly rooted in the minds of the people, and the influence of Mahomedanism, which regards such things with horror, has been powerless to eradicate this. Mr W. W. Skeat's *Malay Magic* (Macmillan, London, 1900) is a compilation of all the writings on the subject of Malay superstitions by the best authorities.

The Malays of the coast are a maritime people, and were long famous for the daring character of their acts of piracy. They are now peaceable fisher-folk, who show considerable ingenuity in their calling. Inland the Malays live by preference on the banks of rivers, building houses on piles some feet from the ground, and planting groves of cocconut, betel-nut, sugar-palm, and fruit-trees around their dwellings. Behind their villages the rice-fields usually spread, and rice, which is the staple food of the people, is the principal article of agriculture among them. Sugar-cane, maize, tapioca, and other similar products are grown, however, in smaller quantities. In planting rice three methods are in use: the cultivation of swamp-rice in irrigated

fields; the planting of ploughed areas; and the planting of hill-rice by sowing each grain separately in holes bored for the purpose. In the irrigated fields the rice plants are first grown in nurseries, and are subsequently transplanted when they have reached a certain stage of development. The Malays also work jungle produce, of which the most important are gutta, rattans, agila wood, camphor wood, and the beautiful *kâmûning* wood which is used by the natives for the hilts of their weapons. The principal manufactures of the Malays are cotton and silk cloths, earthenware and silver vessels, mats, and native weapons. The best cotton cloths are those manufactured by the Bûgis people in Celebes, and the *bâtek* cloths which come from Java and are stamped with patterns. The best silks are produced by the natives of Pahang, Kêlantán, and Johor in the Malay Peninsula. Lord Leighton pronounced the silver ware from Malaya to be the most artistic of any exhibited at the Colonial Exhibition held in London in 1886. The pottery of the Malays is rude but curious. When the first Europeans visited the Malay Archipelago the Malays had already acquired the art of manufacturing gunpowder and forging cannon. The art of writing also appears to have been independently invented by the Malayan races, since numerous alphabets are in use among the peoples of the archipelago, although for the writing of Malay itself the Arabic character has been adopted for some hundreds of years. The Malays are excellent boat-builders.

While the Malays were famous almost exclusively for their piratical expeditions, they naturally bore an evil reputation among Europeans, but now that we have come into closer contact with them, and have learned to understand them better, the old opinions concerning them have been greatly modified. They used to be described as the most cruel and treacherous people in the world, and they certainly are callous of the pain suffered by others, and regard any strategy of which their enemies are the victims with open admiration. In ordinary circumstances, however, the Malay is not treacherous, and there are many instances recorded in which men of this race have risked their own lives on behalf of Europeans who chanced to be their friends. As a race they are exceedingly courteous and self-respecting. Their own code of manners is minute and strict, and they observe its provisions faithfully. Unlike many Orientals, the Malays can be treated with a friendly familiarity without such treatment breeding lack of respect, or leading to liberties being taken with the superior. The Malays are indolent, pleasure-loving, improvident beyond belief, fond of bright clothing, of comfort, of ease, and they dislike toil exceedingly. They have no idea of the value of money, and little notion of honesty where money is concerned. They would always borrow rather than earn money, and they feel no shame in adopting the former course. They will frequently refuse to work for a wage when they most stand in need of cash, and yet at the invitation of one who is their friend they will toil unremittingly without any thought of reward. They are much addicted to gambling, and formerly were much given to fighting, though they never display that passion for war in the abstract which is characteristic of some of the white races, and their courage on the whole is not high if judged by European standards. It is notorious, however, on the coasts that a Malay gang on board a ship invariably gets the better of any fight which may arise between it and the Chinese crew. The sexual morality of the Malays is very lax, but prostitution is not common in consequence. Polygamy, though allowed by their religion, is practised for the most part among the wealthy classes only. The Malays are an intensely aristocratic people, and show a marvellous loyalty to their râjas and chiefs. Their respect for rank is not marred by any vulgarity or snobbery. The ruling classes among them display all the vices of the lower classes, and few of the virtues except that of courtesy. They are for the most part cruel, unjust, selfish, and improvident.

Much has been written concerning the acts of homicidal mania called *âmok*, which word in the vernacular means to attack. It was formerly believed that these outbursts were to be attributed to madness *pur et simple*, and some cases of *âmok* can certainly be traced to this source. These are not, however, in any sense typical, and might equally have been perpetrated by men of another race. The typical *âmok* is usually the result of circumstances which render a Malay desperate. The motive is often inadequate from the point of view of a European, but to the Malay it is sufficient to make him weary of life and anxious to court death. Briefly, where a man of another race might not improbably commit suicide, a Malay runs *âmok*, killing all whom he may meet until he himself is slain.

The nervous affliction called *lâtah*, to which many Malays are subject, is also a curious trait of the people. The victims of this affliction lose for the time all self-control and all sense of their own identity, imitating the actions of any person who chances to rivet their attention. Accounts of these manifestations will be found in Swettenham's *Malay Sketches* (London, 1895, Lane) and Clifford's *Studies in Brown Humanity* (London, 1897, Richards).

**Character,
&c.**

**Religion
and super-
stitions.**

**Mode of
life, &c.**

The Malays wear a loose coat and trousers, and a cap or headkerchief, but the characteristic item of their costume is the *sârong*, a silk or cotton cloth about two yards long by a yard and a quarter wide, the ends of which are sewn together, forming a kind of skirt. This is worn round the waist

Costume, weapons, &c.

folded in a knot, the women allowing it to fall to the ankle, the men, when properly dressed in accordance with ancient custom, folding it over the hilt of their waist-weapon, and draping it around them so that it reaches nearly to the knee. In the hall of a *râja* on state occasions a head-kerchief twisted into a peak is worn, and the coat is furnished with a high collar extending round the back of the neck only. This coat is open in front, leaving the chest bare. The trousers are short and of a peculiar cut and material, being coloured many hues in parallel horizontal lines. The *sârong* is of Celebes manufacture and made of cotton, to the surface of which a high polish is imparted by friction with a shell. The typical fighting costume of the Malay is a sleeveless jacket with texts from the Koran written upon it, short tight drawers reaching to the middle of the thigh, and the *sârong* is then bound tightly around the waist, leaving the hilt of the dagger worn in the girdle exposed to view. The principal weapon of the Malays is the *kris*, a short dagger with a small wooden or ivory handle, of which there are many varieties. The blade of a *kris* may either be wavy or straight, but if wavy the number of waves must always be uneven in number. The *kris* most prized by the Malays are those of Bûgis (Celebes) manufacture, and of these the kind called *tuâsek* are of the greatest value. Besides the short *kris* the Malays use long straight *kris* with very narrow blades, shorter straight *kris* of the same form, short broad swords called *sândang*, long swords of ordinary pattern called *pêdang*, somewhat shorter swords curved like scimitars with curiously carved handles called *chênangkas*, and short stabbing daggers called *tâmbok lada*. The principal tools of the Malays are the *pârang* or *gôtok*, a heavy knife used in the jungle, without which no peasant ever stirs abroad from his house, the *bêlông* or native axe, and the *pisau raut*, which is used for scraping rattan. Their implements are very primitive, consisting of a plough fashioned from a fork of a tree, and a rude harrow. Reaping is usually performed by the aid of a curious little knife which severs each ear of grain separately. The fisher-folk use many kinds of nets, which they manufacture themselves. Sails, paddles, oars, and punting-poles are all in use.

The Malayan language is the *lingua franca* used throughout the archipelago, but in its purest forms it is spoken in the native states of the Malay Peninsula and in the Malay districts of Sumatra. It is a wordy language, having a vocabulary estimated at over 15,000 words exclusive of local terms. The grammar is very simple, the formation of the sentence requiring the nominative to precede the verb, the accusative to follow it, and the adjective and demonstrative pronoun to follow the noun they qualify. The possessive is best formed by placing the word indicating the possessor immediately after the word indicating the thing possessed. There are no inflexions of case or number, but when the plural requires to be emphatically expressed the noun is duplicated. Tenses are indicated by the use of auxiliary verbs, and occasionally merely by the context, yet, though this would appear to be a loose mode of expression, there is never any difficulty experienced in conveying the exact shade of meaning. The language is not easy to speak correctly, on account of its extremely idiomatic nature. In many instances slight shades of meaning are indicated by completely different words—*e.g.*, *pikul*, to carry on the shoulder; *junjong*, to carry on the head; *dûkong*, to carry on the back; *bêban*, to carry on the back as a burden; *kandong*, to carry at the waist or in the womb; *kandar*, to carry suspended from a stick carried over the shoulder; and many other words all indicating to carry. Instances of this kind of minuteness of expression might be multiplied indefinitely. To the educated ear the use of the wrong term is as offensive as a false quantity in Latin. A further difficulty is presented by the number of words to indicate the first person singular, each of which has its complementary pronoun to indicate the second person. Malays attach great importance to the correct use of these terms in polite conversation. In addition to this the idiomatic expressions of the Malays are often somewhat obscure, and cannot be made to bear any meaning if literally translated into a European tongue, though in the vernacular they are exceedingly expressive. Thus it comes to pass that though Malay is a tongue with which it is easy to acquire sufficient familiarity for ordinary conversation, such as is required for simple business transactions and the like, it is found, when a closer knowledge of it is sought, to be a most difficult language for a European to acquire in any perfection. For further information as to the language, see the article MALAYS in the earlier volume of the *Encyclopædia Britannica* (ninth edition).

The Malays cannot, strictly speaking, be said to possess a literature, for none of their writings can boast any literary beauty or value. Their most characteristic literature is to be found not in their writings but in the folk-tales which are transmitted orally from generation to generation, and repeated by the

wandering minstrels called by the people *Pêng-tipor Lâra*, *i.e.*, "Soothlers of Care." Some specimens of these are to be found in the *Journal of the Straits Branch of the Asiatic Society* (Singapore). The collections of *Malay Proverbs* made by Klinkert, Maxwell, and Clifford also give a good idea of the literary methods of the Malays. Their verse is of a very primitive description, and is chiefly used for purposes of love-making. There are numerous rhymed fairy tales which are much liked by the people, but they are of no literary merit. The best Malay story is that of *Hang Tûah*.

Malay States (Federated), the name borne by the native states of the Malay Peninsula which are under the protection of the British Government, though they do not officially form an integral portion of the empire. They are *Pèrak*, *Sêlangor*, and the confederation of small states known as the *Nègri Sêmblân* (nine states) on the west coast of the peninsula, and the state of *Pahang* on the east coast. Each state is under the rule of a sultan, who is assisted in his legislative duties by a state council upon which the Resident has a seat, and which is composed of native chiefs, with Chinese members nominated by the sultan with the advice of the Resident. The administrative work of each state is carried on by the Resident and his staff of European officials, aided by the Malay chiefs and village headmen. The sultan in each case is bound by treaty with the British Government to accept the advice of the Resident, who is therefore practically paramount, though due deference is paid to the wishes of the sultan and his chiefs, and the British officials are pledged not to interfere with the religious affairs of the Mahomedan community. The sultan and his chiefs receive from Government monthly allowances paid from the revenue collected, but all the financial affairs of the country are in the hands of the British officers. The federation of the four states was agreed to by the sultans and chiefs in 1895-96, and the actual federation dates from 1st July 1896, when a Resident-General was appointed to supervise the work of all the Residents, he being responsible to the High Commissioner, who is the Governor of the colony of the Straits Settlements for the time being.

The estimated aggregate area of the Federated Malay States is about 28,000 square miles; the population in 1901 was 517,337, composed as follows:—Europeans, 6589; Eurasians, 7057; Chinese, 227,989; Malays, 213,073; Indians, 58,927; other nationalities, 3702. The actual revenue for the year 1898 amounted to \$15,609,807, the total expenditure being \$12,728,930. The excess of income over expenditure is all the more remarkable as large sums were expended during the year on railway construction, for which purpose a loan of £500,000 has been sanctioned, but the necessity for drawing upon it has not yet arisen. The trade of the federation for 1900 amounted to the following values:—Imports, \$38,402,581; exports, \$60,361,045; total, \$98,763,626. Since 1883 large alluvial deposits of tin ore have been worked in *Pèrak*, *Sêlangor*, and the *Nègri Sêmblân* with marked success.

Prior to that date tin was also exported from these states in considerable quantities, but lack of facilities for transport, &c., checked the output to a great extent. In 1883 the first railways were constructed, and by 1889 the output of tin from the states averaged half the total production of this metal throughout the world. Since then the increase has been considerable, and at the present time the Federated Malay States produce annually nearly 75 per cent. of the tin of the globe. The total output in 1900 was 713,058 piculs or 42,442 tons, as against 644,205 piculs or 38,226½ tons in 1899.

The whole of the Malay Peninsula is one vast forest, through which countless streams flow forming together the most lavish water system in the world. The rivers, though many of them are imposing in appearance, are uniformly shallow, only a few of them on the west coast being navigable by ships for more than 40 miles from their mouths. (For information on the botany, geology, &c., of the Malay states see MALAY PENINSULA.)

Pêrak is situated between the parallels 3° 37' and 6° 05' N. and 100° 3' to 101° 51' E. on the western side of the Malay Peninsula. It is bounded on the N. by the British possession of Province Wellesley and the Malay state of Kédah; on the S. by the protected native state of Sélángor; on the E. by the protected native state of Pahang and the independent states of Kélangan and Pétáni; and on the W. by the Straits of Malacca. The coast-line is about 90 miles in length. The extreme distance from the most northerly to the most southerly portions of the state is about 172 miles, and the greatest breadth from east to west is about 100 miles. The total area of the country is estimated at about 10,000 square miles. The *Pêrak*

Pêrak. river, which runs in a southerly direction almost parallel with the coast for nearly 150 miles of its course, is navigable for small steamers for about 40 miles from its mouth, and by native trading boats for nearly 200 miles. The Plus, Bâtang, Pâdang, and Kinta rivers are its principal tributaries, all of them falling into the *Pêrak* on its left bank. The other principal rivers of the state are the Krian, Kûrau, Lârut, and Brîas to the north of the mouth of the *Pêrak*, and the Bêrnâ to the south. None of these rivers are of any great importance as waterways, although the Bêrnâ river is navigable for small steamers for nearly 100 miles of its course. The mountain ranges, which cover a considerable area, run from the north-east to the south-west. The highest altitudes attained by them do not exceed 7500 feet, but they average about 2500 feet. They are all thickly covered with jungle. The ranges are two in number, running parallel to one another, with the valley of the *Pêrak* between them. The larger is a portion of the main chain which runs down the peninsula from north to south. The lesser is situated in the district of Lârut. There are several hill sanatoria in the state at heights which vary from 2500 to 4700 feet above sea-level, but the extreme humidity of the atmosphere renders the coolness thus obtainable the reverse of enjoyable.

Mr Leonard Wray, the curator of the *Pêrak* museum, writes as follows on the subject of the geological formation of the state:—

Geology. "There are really only four formations represented— firstly, the granitic rock; secondly, a large series of beds of gneiss, quartzite, schist, and sandstone, overlaid in many places by thick beds of crystalline limestone; thirdly, small sheets of trap rock; and fourthly, river-gravels and other Quaternary deposits. The granites are of many varieties, and also, in all probability, of several different geological periods. The series of quartzites, schists, and limestone are of great age, but as no fossils have ever been found in any of them, nothing definite can be stated as to their exact chronological position. Their lithological characteristics and the total absence of all organic remains point to the Archæan period. The failure to discover signs of life in them is, of course, merely negative evidence, and the finding of a single fossil would at once upset it. However, until this happens they may be conveniently classed as Laurentian. It is at present impossible to form anything approaching an accurate estimate of the thickness of this extensive series, but it is probable that it is somewhere between 4000 and 5000 feet. Unconformability has been noticed between the limestones and the beds beneath, but whether this is sufficient to separate them or not is a matter for future investigation. . . . The taller hills are exclusively composed of granite, as also are some of the lower ones. . . . The ores of the following metals have been found in the formations named:— granite—tin, lead, iron, arsenic, tungsten, and titanium; Laurentian—tin, gold, lead, silver, iron, arsenic, copper, zinc, tungsten, manganese, and bismuth; Quaternary—tin, gold, copper, tungsten, iron, and titanium. This is not to be considered a complete list, as small quantities of other metals have also been found."

The early history of *Pêrak* is obscure, the only information on the subject being obtained from native traditions, which are altogether untrustworthy. According to these authorities, however, a settlement was first made by Malays in *History.* *Pêrak* at Brîas, and the capital was later moved to the banks of the *Pêrak* river, the site chosen being a little village called Têmong, which lies some miles up stream from Kuâla Kangsar, the present residence of the sultan. When the Malacca sultanate fell owing to the invasion of the Portuguese in 1511, a member of that royal house is said to have migrated to *Pêrak*, and the present dynasty claims to have been descended from him. As this boast is also made by almost every ruling family in the peninsula, the tradition is not worthy of any special attention. What is more certain is the tradition that *Pêrak* was twice invaded by the Acheenese, and its rulers carried off into captivity, one of them, Sultan Mansur Shah, subsequently becoming the ruler of Acheen. The first European settlement in *Pêrak* was made by the Dutch in 1650, under a treaty entered into with the Acheenese, but the natives of the country rose against the Dutch again and again, and it was abandoned in 1783, though it was afterwards reoccupied, the Dutch being finally ejected by the British in 1795. In 1818 the Siamese conquered *Pêrak*, but its independence was secured by a treaty between the British and Siamese Governments in 1824. From that date until 1874 *Pêrak* was ruled by its own sultans, but in that year, owing to internal strife, Sultan Abdullah applied to the then Governor of the Straits Settlements, Sir Andrew Clarke, for the assistance of a British Resident. The treaty of Pangkor was concluded on 20th January 1874, and the first Resident, Mr J. W. W. Birch, was murdered on 2nd November 1875. A punitive expedition became necessary; Sultan Abdullah and the other chiefs concerned in the murder were banished, the actual murderers were hanged, and Râja Mûda Jusuf was declared regent. Sir Hugh Low was appointed Resident, a position which he held until 1899, when he was succeeded by Sir Frank Swettenham. Since then the history of *Pêrak* has been one of continuous peace and growing prosperity and wealth.

By the census taken on 5th April 1891 the population of *Pêrak* was shown to be as follows:—Europeans, 366; Eurasians, Jews, and Armenians, 293; Malays, 96,719; Chinese, 94,345; Tamils, 13,086; aborigines, 5779; other nationalities, 3666; thus making a grand total of 214,254, of whom *Popu-*
lation. 156,408 were males and 57,846 were females. The estimated population in 1898 was 277,461, but owing to the disparity of the proportions between the sexes the deaths in each year largely outnumber the births, and the increase in the population is accounted for solely by the number of immigrants, chiefly from the mainland of China, and to a lesser extent from India also.

The revenue of *Pêrak* in 1874 amounted to only \$226,333. That for 1900 amounted to \$7,636,126. Of this latter sum \$3,570,631 was derived from duty on tin exported, \$1,017,618 from railway receipts, \$351,451 from land revenue, and \$89,857 *Finance,*
trade, &c. from postal and telegraphic revenue. The balance is mainly derived from the revenue farms which are leased to Chinese capitalists for a term of years, being for the right to collect import duties on opium and spirits, and to keep licensed gambling and pawnbroking shops. The expenditure for 1900 amounted to \$6,144,774. Of this sum \$2,417,990 was expended upon railway upkeep and construction, and \$1,229,295 on public works. The value of the imports during 1900 was \$14,741,148; that of the exports, \$29,190,663; total, \$43,931,811. Tin is the principal export from the state. The following table shows the amount exported between 1896 and 1900, with the Singapore price of refined tin at the time of export, and the value of each year's output:—

Year.	Tons.	Price per Picul.	Value.
1896	22,811	\$32.20	\$12,339,909
1897	20,949	36.09	12,701,695
1898	19,703	42.96	14,177,101
1899	18,960	72.52	23,099,506
1900	21,166	74.15	26,032,000

The diminished output is stated not to be due to the exhaustion of the tin resources of the state—that will not come for many years yet—but to the scanty labor supply. The latter is ascribed to increased demand for Chinese labour in China and French Indo-China, and the Dutch colonies, and also to the low price which has ruled for some years. In 1900 the price of tin rose higher than in any year of the decade 1891–1900. The sugar exported from *Pêrak* in 1898 was valued at \$1,214,701, and the coffee at \$48,664.

Although so much has been done to develop the resources of *Pêrak*, by far the greater portion of the state is still covered by dense forest. In 1898 it was calculated that only *General.* 330,249 acres of land were occupied or cultivated out of a total acreage of 6,400,000. A line of railway connects the port of

Teluk Anson with the great mining district of Kinta, whence the line runs on to Kuala Kangsar, the residence of the sultan; and an extension thence to Larut and from Larut to Province Wellesley, opposite Penang, is in course of construction. There are also several hundred miles of excellent metalled roads. For administrative purposes the state is divided into six districts:—Upper Perak, Kuala Kangsar, and Lower Perak, on the Perak river; Kinta; Larut, and Krian. Of these, Larut and Kinta are the principal mining centres, while Krian is the most prosperous agricultural district. The districts on the Perak river are mostly peopled by Malays. The administrative capital is Taiping, the chief town of Larut. Kuala Kangsar is chiefly memorable as having been the scene of the first federal meeting of native chiefs, who, with the British Residents from each state, met together in 1897 for friendly discussion of their common interests for the first time in history, under the auspices of the High Commissioner, Sir Charles H. B. Mitchell. This, in the eyes of those who are acquainted with the character of the Malays and of the relations which formerly subsisted between the rulers of the various states, is perhaps the most signal token of the changes which British influence has wrought in the peninsula.

Selangor is situated between the parallels $2^{\circ} 32'$ and $3^{\circ} 37'$ N. and $100^{\circ} 38'$ and 102° E., on the western side of the Malay Peninsula. It is bounded on the N. by the protected native state of Perak, on the S. by the protected states of the Nègri Sembilan, on the E. by Pahang and the Nègri Sembilan, and on the W. by the Straits of Malacca. The coast-line is about 100 miles in length, greatest length about 104 miles, and greatest breadth about 48 miles, total area estimated at about 3000 square miles. The state consists of a narrow strip of land between the mountain range which forms the backbone of the peninsula and the Straits of Malacca. Compared with other states in

Selangor. the peninsula, Selangor is poorly watered. The principal rivers are the Selangor, the Klang, and the Langat. The principal port of the state is situated at the mouth of the Klang river, and is connected with the capital, Kuala Lumpur, by a railway. The geology of the state closely resembles that of Perak. The state is possessed of most valuable deposits of alluvial tin, and mining for this metal is the chief industry of the population.

According to native tradition, the ruling house of Selangor is descended from a Bûgis rāja, who, with two of his brothers, settled in the state in 1718, the son of the youngest brother

History. eventually becoming ruler of the country. In 1783 the then sultan of Selangor joined with the Iang-di-pér-Tuan Muda of Riouw in an unsuccessful attack upon the Dutch who then held Malacca. In retaliation the Dutch, under Admiral Van Braam, invaded Selangor and drove the sultan out of his country. In 1785, aided by the Bëndahāra of Pahang, Sultan Ibrahim of Selangor reconquered his state; but the Dutch blockaded his ports, and eventually forced him to enter into a treaty whereby he consented to acknowledge their sovereignty. The earliest British political communication with Selangor began in 1818, when a commercial treaty was concluded with the Governor of Penang. In 1867 Sultan Abdul Samad of Selangor appointed his son-in-law, Tûngku Kudin, to be viceroy; and this gave rise to a civil war which lasted almost without intermission till 1873, when the enemies of Tûngku Kudin were finally vanquished, largely by the agency of the Bëndahāra of Pahang, who, at the invitation of the Governor of the Straits Settlements, sent a warlike expedition to the assistance of the viceroy. In 1874 the occurrence of an atrocious act of piracy off the mouth of the Langat river led to the Governor, Sir Andrew Clarke, appointing, at the request of the sultan, a British Resident to aid him in the administration of his kingdom. Since that date there has been no further breach of the peace, and the prosperity of Selangor has increased annually.

By the census taken on 6th April 1891 the population of Selangor was shown to be as follows:—Europeans, 190; Eurasians, 167; Malays, 23,750; Chinese, 50,844; aborigines, 1224; Tamils, 3082; other nationalities, 2335, thus making a total of 81,592, of whom 67,051 were males and 14,541 were females. It will be noted that the population of this once Malayan state is now Chinese to the extent of more than 60 per cent. of the whole. The estimated population in 1898 amounted to 150,000, and of this probably 75 per cent. at the least was Chinese, the increase of the population being due entirely to the influx of labourers from the mainland of China attracted by the richness of the alluvial tin mines. Here, as elsewhere in the Malay Peninsula, the deaths annually far outnumber the births recorded, the disproportion of the female to the male sections of the population being greater in Selangor than in other parts of the colony and Federated States. The development of planting enterprise in Selangor, and more especially the cultivation of coffee, has led to a certain immigration of Tamil coolies, but the number of Tamils is still insignificant if compared with that of the Chinese population.

The revenue of Selangor in 1875 amounted to only \$115,656; in 1900 it had increased to \$6,303,165. Of this latter sum \$2,695,828

was derived from duty on tin exported, \$1,072,378 from railway receipts, \$255,899 from land revenue, and \$67,937 from postal and telegraphic revenue. The balance is chiefly derived from the revenue farms, which include the right to collect import duty on opium and spirits. The expenditure for 1900 amounted to \$4,944,160, of which sum \$2,276,510 was expended upon railways and \$833,722 on public works. The value of the imports in 1900 was \$18,406,570, and that of the exports was \$21,798,444, making a total of £40,205,014. Tin is the principal export. The amount exported in 1898 was 16,301 tons, but in 1900 it was 16,041 tons. The decrease is attributed by the Resident to scarcity of labour rather than to any deficiency of good mining ground. The total area of alienated mining land at the end of 1898 amounted to 39,532 acres, and it was estimated that 50,000 Chinese were employed in the mines. Coffee, rice, pepper, and gambier are all grown with success in Selangor, but the state practically exists at the present time only as a mining country. Had it to depend upon its agricultural products for its revenue, it would speedily become bankrupt. Every effort is being made, however, to stimulate planting enterprise against the day, probably far distant still, when the alluvial tin deposits will become exhausted. No true lode has hitherto been discovered in Selangor.

The total length of railway line open to traffic at the end of 1898 was $77\frac{1}{2}$ miles, and on 1st January 1899 a further section of $5\frac{1}{2}$ miles was declared open. There is now railway communication not only between the port of Klang and the capital, Kuala Lumpur, but between that place and Ulu Selangor, a distance of 36 miles, and Ulu Langat, a distance of nearly 20 miles. Railways are also in course of construction which will eventually join the Selangor system to that of Perak on the north and that of the Nègri Sembilan on the south. Frequent communication is maintained by steamer between Klang and Singapore, and by coasting vessels between the former port and those on the coast of the peninsula.

For administrative purposes Selangor is divided into six districts—Kuala Lumpur, in which the capital and the principal tin-fields are situated; Ulu Selangor, which is also a prosperous mining district; Kuala Selangor, which is agricultural, and poorly populated by Malays; Ulu Langat, mining and agricultural; Kuala Langat, the residence of the late sultan Abdul Samad, agricultural; and Klang, the only prosperous port of the state. Much money has been expended upon the capital, Kuala Lumpur, which possesses some fine public buildings, water-works, &c., and where the principal residence of the Resident-General is situated. In some sort Kuala Lumpur is the capital not only of Selangor, but also of the whole federation. Its scenery is very attractive.

Nègri Sembilan (the Nine States) is a federation of small native states which is now treated as a single entity, being under the control of a British Resident, and is situated between parallels $2^{\circ} 28'$ and $3^{\circ} 18'$ N. and $101^{\circ} 45'$ and $102^{\circ} 45'$ E., on the western side of the Malay Peninsula. It is bounded on the N. by the protected state of Pahang, on the S. by the territory of Malacca, on the E. by Pahang and the independent state of Johor, and on the W. by the Straits of Malacca. The coast-line is about 28 miles in length, and the extreme distance from north to south is 55 miles, and that from east to west about 65 miles. The estimated area is about 3000 square miles. Arang-Arang, or Port Dickson, is the only port on the coast. It is connected with the capital, Seremban, by a railway 24 miles in length. Most of the states comprising the federation depend largely for their prosperity upon agriculture, but in some of the districts tin is being worked in considerable quantities, with good results.

As is the case with the history of most Malayan states, much rests upon no surer ground than tradition, in so far as the records of the Nègri Sembilan are concerned. At the same time the native story that the states which now form the federation of the Nègri Sembilan were originally peopled by tribes of Sâkai, or aborigines of the peninsula, who descended from the mountains of the interior and peopled the valleys, is supported by much corroborative evidence. Not only does the Malay's contempt for the Sâkai make it exceedingly unlikely that the tradition, which is hardly a matter for pride, should have been preserved if it were not true, but also many of the laws and customs in force in these states are wholly foreign to those of the Malays, and can plainly be traced to the aborigines. As an instance, the custom of inheriting rank and property through the mother instead of through the father may be mentioned. Tradition further relates that towards the end of the 18th century a rāja of the royal house of Ménangkâbu came from Sumatra to rule over the federation of small states, each of which continued to be governed in all its local affairs by its own chief and by the village and other councils sanctioned by ancient custom. The Sumatran rāja took the title of Iang-di-pér-Tuan of Sri Ménanti. Although they bore the name of the "Nine States," only six seem to have belonged to the federation during the time of which history speaks. These are

History.

Sri Mēnanti, Johol, Tampin, Rēmbau, Jēlēbu, and Sūngei Ujong. Later the two latter separated themselves from the confederation. Ancient tradition says that the names of the nine states were originally Klang, Jēlēbu, Sūngei Ujong, Johol, Sēgāmat, Pāsir Bēsar, Nāning, Rēmbau, and Jēlai. Of these Klang was annexed by Sēlāngor, Sēgāmat and Pāsir Bēsar by Johor, and Nāning by Malacca. During the last years of the 18th century the lang-di-pēr-Tūan appointed an lang-di-pēr-Tūan Mūda to rule Rēmbau, and the state of Tampin was created for the family of the new chief. In 1887 the Governor of the Straits Settlements sent Mr Martin Lister to the Nēgri Sēmbilan, which had become disintegrated, and by his influence the ancient federal system was revived under the control of a Resident appointed by the Governor. The states which formed this new confederation were Johol, Ulu Mūtar, Jēmpol, Tērāchi, Inas, Gūnong Pāsir, Rēmbau, Tampin, and Gēmēncheh. Prior to this, in 1873, owing to a civil war in Sūngei Ujong, Sir Andrew Clarke sent a military force to that state, put an end to the disturbances, and placed the country under the control of a British Resident. Jēlēbu was taken under British protection in 1886, and was thenceforth managed by a magistrate under the orders of the Resident of Sūngei Ujong. In 1896, when the federation of all the Malayan states under British control was effected, Sūngei Ujong and Jēlēbu were reunited to the confederation of small states from which they had so long been separated, and the whole, under the old name of the Nēgri Sēmbilan, or Nine States, was placed under one Resident.

The population of the Nēgri Sēmbilan, according to the census taken in April 1891, amounted to 70,730. It is now estimated

that the population has increased to 85,000, but no trustworthy figures on the subject are obtainable. In

1893, however, the number of arrivals at the ports of the state exceeded the departures by 3646. The births registered slightly exceed the deaths, there being a large Malayan population in these states, among whom there is a fair proportion of women to men, a condition of things which is not found in the states most visited by Chinese immigrants.

The revenue of the Nēgri Sēmbilan amounted to only \$223,435 in 1888. In 1898 it had increased to \$701,334, and in 1900 amounted to \$1,251,366. The revenue of 1900 was derived

mainly as follows—land revenue, \$125,168; railway receipts, \$83,180; duty on tin, \$692,519; the balance being chiefly due to the revenue farms. The expenditure in 1900 amounted to \$1,009,318. The trade returns for 1900 show a total value of \$11,330,000. Of this sum two-fifths is represented by the value of the exports, \$4,281,457 being the value of the tin exported, and \$1,065,000 the value of agricultural produce exported. The latter is chiefly coffee, jungle produce, pepper, and gambier. The output of tin in 1900 amounted to 74,300 piculs. At the end of that year there were 15,000 persons working in the tin mines.

The only line of railway open to traffic at the end of 1898 was that from Port Dickson to Sērēmban, which is 24½ miles in length.

During the year 223 miles of cart-road and 174 miles of bridle-paths were open to traffic. A railway is now in course of construction which, when completed, will join Sērēmban to Malacca on the south and to Kuāla Lūmpor on the north. Frequent communication with the ports of the colony and of the native states on the Straits of Malacca by coasting vessels is maintained.

For administrative purposes the Nēgri Sēmbilan is divided into five districts, viz., the Sērēmban District, the Coast District, Jēlēbu, Kuāla Pilah, and Tampin. Each of these is under the charge of a European district officer, who is responsible to the Resident. The lang-di-pēr-Tūan lives at Kuāla Pilah, but the capital of the federation is at Sērēmban in Sūngei Ujong, where the Resident is stationed. The hereditary chiefs of the various states aid in the government of their districts, and have seats upon the state council, over which the lang-di-pēr-Tūan presides. The watering-place of Magnolia Bay, where excellent sea-bathing is obtainable, is one of the pleasure resorts of this part of the peninsula.

Pahang, on the east coast of the peninsula, is situated between parallels 2° 28' and 3° 45' N. and 101° 30' and 103° 30' E. It is bounded on the N. by the independent native states of Kēlantān and Trēnggānu; on the S. by the Nēgri Sēmbilan and Johor; on the E. by the China Sea; and on the W. by the protected states of Pērak and Sēlāngor. The coast-line is about 112 miles in length; and the greatest length is about 210 miles, and greatest breadth about 130 miles. The state is the largest in the peninsula, its area being estimated at 15,000 square miles. The ports on the coast are the mouths of the Endau, Rompin, Pahang, and Kuantan rivers, but during the north-east monsoon the coast

is not easy of approach, and the rivers, all of which are guarded by difficult bars, are impossible of access except at high tides. The principal river of the state is the Pahang, from which it takes its name. At a distance of 180 miles from the coast this river is formed by two others named respectively the Jēlai and the Tēmbēling. The former is joined 20 miles farther up stream by the Līpis, which has its rise in the mountains

which form the boundary with Pērak. The Jēlai itself has its rise also in a more northerly portion of this range, while its two principal tributaries above the mouth of the Līpis, the Tēlom and the Sērau, rise, the one in the plateau which divides Pērak from Pahang, the other in the hills which separate Pahang from Kēlantān. The Tēmbēling has its rise in the hills which divide Pahang from Kēlantān, but some of its tributaries rise on the Trēnggānu frontier, while the largest of its confluent comes from the hills in which the Kuantan river takes its rise. The Pahang is navigable for large boats as far as Kuāla Līpis, 200 miles from the mouth, and light-draught launches can also get up to that point. Smaller boats can be taken some 80 miles higher up the Jēlai and Tēlom. The river, however, as a waterway is of little use, since it is uniformly shallow. The Rompin and Kuantan rivers are somewhat more easily navigated for the first 30 miles of their course, but taken as a whole the waterways of Pahang are of little value. The interior of Pahang is chiefly noted for its auriferous deposits. Gūnong Tāhan is situated on the boundary between Pahang and Kēlantān. Its height is estimated at 8000 feet above sea-level, but it has never yet been ascended. Pahang, like the states on the west coast, is covered almost entirely by one vast forest, but in the Līpis valley, which formerly was thickly populated, there is a considerable expanse of open grass plain unlike anything to be seen on the western sea-board. The coast is for the most part a sandy beach fringed with *casuarina* trees, and there are only a few patches of mangrove-swamp throughout its entire length.

The ancient name of Pahang was Indrapūra. It is mentioned in the history of *Hang Tūah*, the great Malacca brave, who flourished in the 16th century, and who succeeded in abducting a daughter of the then ruling house of Pahang for his master, the sultan of Malacca. Prior to this, Pahang had been ruled by the Siamese. When Malacca fell into the hands of the Portuguese in 1511 the sultan, Muhammad Shah, fled to Pahang, and the present ruling house claims to have been descended from him. The title of the ruler of Pahang was Bēndāhāra until 1882, when the present (1902) ruler, Wan Ahmad, assumed the title of sultan, taking the name of Sultan Ahmad Maatham Shah. Up to that time the Bēndāhāra had been installed on his accession by the sultan of Riau, and held his office by virtue of that chief's letter of authority. About 1855 the father of the present sultan died at Pēkan, and his son Bēndāhāra Korish, who succeeded him, drove Wan Ahmad from the country. After making three unsuccessful attempts to conquer the land and to dethrone his elder brother, Wan Ahmad at last succeeded in 1865 in invading the state and wresting the throne from his nephew, who had succeeded his father some years earlier. From that time, in spite of two attempts to shake his power by invasions from Sēlāngor which were undertaken by his nephews Wan Aman and Wan Da, Bēndāhāra Ahmad ruled his country with a rod of iron. In 1887 he consented to enter into a treaty with the Governor of the Straits, by which he accepted a Consular Agent at his court. This treaty was finally signed on 8th October 1887. In February of the following year a Chinese British subject was murdered at Pēkan in circumstances which pointed to the responsibility of the sultan for the crime, and in October 1888 a Resident was appointed to assist the sultan in the administration of his country, that being, in the opinion of the British Government, the only guarantee for the safety of the life and property of British subjects which it could accept. In December 1891 disturbances broke out in Pahang, the nominal leaders of which were certain of the sultan's most trusted chiefs. The sultan himself took no part in the outbreak, but it undoubtedly had his sympathy, even if it was not caused by his direct commands. The rebels were driven to seek safety in flight in November 1892, but in June 1894 they gathered strength for a second disturbance, and raided Pahang from Kēlantān, in which state they had been given shelter by the Mahommedan rulers. This event, added to the occurrence of other raids from across the border, led to an irregular expedition being led into Trēnggānu and Kēlantān by the Resident of Pahang (Mr Hugh Clifford) in 1895, and this had the desired result. The rebel chiefs were banished to Siam, and no further breach of the peace has troubled the tranquillity of Pahang since that time. Pahang joined the Federated Malay States by a treaty signed in 1895, and the sultan and his principal chiefs were present at the federal durbar held at Kuāla Kangsar in Pērak in 1897.

The census taken in Pahang in April 1891 was neither complete nor trustworthy, the country being at that time newly acquired territory, and the machinery for taking such statistics by no means efficient. The figures then obtained gave the total population of the state as 57,642, of whom 50,527 were Malays, 3241 Chinese, and 2032 Sākai, or aboriginal tribes. Of the latter it is estimated that several thousands escaped enumeration, and at least 3000 Malays also escaped the census. It is estimated that the population at the present time, which has been augmented since 1891 by the influx of both Chinese and foreign

Popula-
tion.

Malays, exceeds 80,000. In former days Pahang was far more thickly populated than in modern times, but the long succession of civil wars which racked the land after the death of Bēndāhāra Ali caused thousands of Pahang Malays to fly the country. To-day the valley of the Lēbir river in Kēlantān and the upper portions of several rivers on the Pērak and Sēlāngor boundaries are inhabited by Pahang Malays, the descendants of these fugitives. The Pahang natives are almost all engaged in agriculture. The work of the mines, &c., is performed by Chinese and foreign Malays. In the Lipis valley the descendants of the Rāwa Malays, who at one time possessed the whole of the interior in defiance of the Pahang rājas, still outnumber the people of the land.

The revenue of Pahang in 1889 amounted to only \$62,077; in 1899 it was \$300,000, and in 1900 had increased to \$419,150. The expenditure in 1900 amounted to \$630,678. Pahang is still a source of expense to the federation, its progress having been retarded by the disturbances which lasted from December 1891 until 1895, with short intervals of peace; but the revenue is now steadily increasing, and the ultimate financial success of the state is considered to be secure. Pahang owes something over \$3,500,000 to Sēlāngor, which has financed it now for some years out of surplus revenue. The value of the imports in 1900 was \$973,405, that of the exports was \$2,322,950, thus making a total trade value of \$3,295,355. The most valuable export was gold, worth \$680,000. The tin ore exported amounted to 15,728 piculs.

The geological formation of the states lying to the eastward of the main range of mountains which splits the peninsula in twain differs materially from that of the western states. At

General. A distance of about a dozen miles from the summits of the mountains the granite formation is replaced by slates, which in many places are intersected by fissures of quartz, and in others are overlaid by vast thicknesses of limestone. Those of the quartz fissures which have been exploited are found to be auriferous, and several European mining companies are now working these deposits of gold with some success. The Raub mine, near the foot of the mountains, is said to be likely to take rank as a fine gold-mine, and there is every reason to believe that Pahang possesses other gold-mines of equal value. These mines are now being worked by electric power generated by water-power, and transmitted by overhead wires for a distance of 7 miles. A magnificent road over the mountains, with a ruling grade of 1 in 30, joins Kuāla Lipis, the administrative capital of Pahang, to Kuāla Kūbu, the nearest railway station in Sēlāngor. The road measures 82 miles in length. Pēkan, where the sultan has his residence, was the capital of Pahang until the middle of 1898, when the administrative headquarters were transferred to the interior as being more central. None of these towns is of any size or importance. In the Kuantan valley, which lies parallel to the Pahang river, a European company is working tin lodes with considerable success. These lodes are the only mines of the kind being worked in the Federated Malay States. Pahang is fertile and well suited for agriculture of many kinds. The rainfall is heavy and regular. The climate is cooler than that of the west coast, and the full force of the monsoon is felt from October to February in each year. For administrative purposes Pahang is divided into four districts—Ulu Pahang, in which the present capital is situated; Tēmērlōh, which includes 80 odd miles of the Pahang valley and the Sēmantan river; Pēkan, which includes the coast rivers down to Endau; and Kuantan. Each of these is under the charge of a district officer, who is responsible to the Resident. The boundary with Johor and the Nēgri Sēmbilan was rectified by a commission which sat in London in 1897-98.

Maláyr, a small province of Persia, situated between Hamadan and Burújird. It has a population of about 70,000, and, together with the district Túsirkán, pays a yearly revenue of about £13,000. Its capital and seat of government is Doletábád (Dowletábád), a thriving and prosperous little city, with a population of about 5000, situated, at an elevation of 5680 feet, 38 miles from Hamadan and 32 miles from Burújird. It has post and telegraph offices.

Malchin, a town of Germany, grand-duchy of Mecklenburg-Schwerin, on the river Peene, between Lakes Malchin and Kummerow, 28 miles by rail north-west of Neu-Brandenburg. It is, alternately with Sternberg, the place of assembly of the Mecklenburg Diet. Here are the châteaux of Remplin, Basedow, and Schlitz; a 4th-century church, and a large town hall. Population (1900), 7449.

Malda, a district of British India, in the Bhagalpur division of Bengal. The administrative headquarters are at English Bazar, near the town of Old Malda.

Area, 1902 square miles; population (1881), 711,487; (1891), 814,919; (1901), 884,443, showing an increase of 15 per cent. between 1881 and 1891, and of 8·5 between 1891 and 1901; average density, 464 persons per square mile. Classified according to religion, Hindus in 1891 numbered 409,136; Mahommedans, 384,651; Christians, 72, of whom 23 were Europeans; "others," 21,060. The land revenue and rates in 1897-98 were Rs.4,66,863; number of police, 278; number of boys at school (1896-97), 13,181, being 22 per cent. of the male population of school-going age; registered death-rate (1897), 33·6 per thousand. The two principal industries are indigo and silk, but both are declining. There are two indigo concerns, and four factories, employing about 3000 persons, with an out-turn of 1600 mannds, valued at Rs.2,00,000; and two silk filatures, employing 1000 persons, with an out-turn of 50,000 lb, valued at Rs.3,00,000. No railway touches the district, but the communications by water are good.

Malden, a city of Middlesex county, Massachusetts, U.S.A., in the eastern part of the state. It is 5 miles north of Boston, of which it is a suburb. Its plan is irregular, it is divided into seven wards, it derives its water supply from Spot Pond, and few of its streets are paved. It is on the Boston and Maine railroad. It is largely a residential city, and its manufactures are not extensive. In 1900 its manufacturing establishments numbered 242, with a capital of \$5,906,279. They employed an average number of 3082 hands, and their product had a value of \$7,959,292. The assessed valuation of real and personal property in 1900 was \$27,287,540, the net debt of the city was \$1,522,944, and the rate of taxation was \$16·70 per \$1000. Population (1880), 12,017; (1890), 23,031; (1900), 33,664, of whom 9513 were foreign-born and 446 were negroes. The death-rate in 1900 was 14·4.

Maldivé Islands, an archipelago in the Indian Ocean, lying between 7° 6' N. and 0° 42' S. and 72° 33' and 73° 44' E. The group was again visited and surveyed in 1899-1900 by Mr J. Stanley Gardiner and Mr C. Forster Cooper, who found that as many as 300 of the atolls were at that time inhabited. The natives, who are estimated at about 30,000 Mahommedans, are classed by these observers in four ethnological divisions. 1. Those of the northern atolls, which are separated from the rest by the Kardiva channel, 35 miles broad and exposed to strong cross-currents during the monsoons. Here the reefs are less perfect, seldom forming complete central lagoons, and as they were formerly exposed to the constant attacks of the Mopillah pirates from India, the people are hardier and more vigorous than their less warlike southern neighbours. They annually visited the coasts of India or Ceylon, concluded treaties with the rajahs against the corsairs, and often married Indian wives, thus acquiring distinct racial characters of an approximately Dravidian type. 2. Those of the central division, comprising ten atolls crowded together between North Male and Haddumati, who are under the direct rule of the sultan, and have been more exposed to Arab influences. They formerly traded with Arabia and Malaysia, and many Arabs settled amongst them, so that they betray a strong strain of Semitic blood in their features. 3 and 4. The natives of Suvadiva, Addu, Mulaku, and the other southern clusters, who have had little communication with the Central Male

people, and probably preserve more of the primitive type, approximating in appearance to the Singhalese villagers of Ceylon. They are an intelligent and industrious people, growing their own crops, manufacturing their own cloth and mats, and building their own boats, while many read Arabic more or less fluently, although still believers in magic and witchcraft. Mr Gardiner also visited the hitherto little known MINIKOI atoll, which lies in 8° 15' N. and 73° E., 110 miles from the Laccadives, 71 miles from the Maldives, and 215 miles from the nearest point on the coast of India. The atoll, which is pear-shaped and disposed in the direction from south-west to north-east, is 5 miles long, with an extreme breadth of nearly three miles, with a large but shallow lagoon approached from the north by a passage 2 fathoms deep. At present the atoll is growing outwards on every side, and at one place rises 19 feet above sea-level. The population, which numbered a little over 3000 in 1899, is sharply divided into five castes, of which the highest three are pure Maldivan, the lower two the same as the rest of the Laccadives. All are centred in a small village opposite Mou Rambu Point on the west or lagoon side; but most of the men are generally absent, many being employed with the Lascar crews on board the large liners plying in the Eastern seas. The numerous wrecks on its reefs, its lighthouse, and its position on the track of all eastward-bound vessels make Minikoi a familiar sight to seafarers in those waters.

See *Proceedings of the Cambridge Philosophical Society*, vol. xi. Pt. 1. (1900). (A. H. K.)

Maler Kotla, a native state of India, within the Punjab. It ranks as one of the cis-Sutlej states, which came under British influence in 1809. The territory lies south of Ludhiana. Area, 162 square miles; population (1891), 75,755; average density, 467 persons per square mile. In 1901 the population was 77,506, showing an increase of 2 per cent. The estimated gross revenue is Rs.3,02,000; the military force numbers 280 men; and there is no tribute. The chief, whose title is nawab, is an Afghan. In consequence of his insanity, the administration is conducted by the nawab of Loharu. It is proposed to construct a railway through the state, and partly out of its revenues, from Ludhiana to Jhakhal on the Southern Punjab line. In 1896-97 the number of schools was 22, attended by 837 pupils, of whom 60 were girls; the proportion of boys at school was as high as one in 48 of the total male population. The town of MALER KOTLA is 30 miles south of Ludhiana. Population (1891), 21,754.

Mallarmé, Stéphane (1842-1898), French poet and theorist, was born at Paris, 18th March 1842. His life was simple and without event. His small income as professor of English in a French college was sufficient for his needs, and, with his wife and daughter, he divided the year between a fourth-floor flat in Paris and a cottage on the banks of the Seine. His Tuesday evening receptions, which did so much to form the thought of the more interesting of the younger French men of letters, were almost as important a part of his career as the few carefully elaborated books which he produced at long intervals. *L'Après-midi d'un Faune* (1876) and other fragments of his verse and prose had been known to a few people long before the publication of the *Poésies complètes* of 1887, in a facsimile of his clear and elegant hand-writing, and of the *Pages* of 1891 and the *Vers et Prose* of 1892. His remarkable translation of the poems of Poe appeared in 1888, the "Raven" having been published as early as 1875, with illustrations by Manet. *Divagations*, his own final edition of his prose, was published in 1897, and a more or less complete edition of the *Poésies*,

posthumously, in 1899. He died at Valvins, Fontainebleau, 9th September 1898. All his life Mallarmé was in search of a new æsthetics, and his discoveries by the way were often admirable. But he was too critical ever to create freely, and too limited ever to create abundantly. His great achievement remains unfinished, and all that he left towards it is not of equal value. There are a few poems and a few pieces of imaginative prose which have the haunting quality of Gustave Moreau's pictures, with the same jewelled magnificence, mysterious and yet definite. His later work became more and more obscure, as he seemed to himself to have abolished limit after limit which holds back speech from the expression of the absolute. Finally, he abandoned punctuation in verse, and invented a new punctuation, along with a new construction, for prose. Patience in the study of so difficult an author has its reward. No one in our time has vindicated with more pride the self-sufficiency of the artist in his struggle with the material world. To those who knew him only by his writings, his conversation was startling in its clearness; it was always, like all his work, at the service of a few dignified and misunderstood ideas. (A. S.)

Malleco, a province of Southern Chile, situated between 37° 46' and 38° 30' S. and 71° 40' and 73° 10' W., and bounded by the province of Bio-Bio on the N. and E., by that of Cautin on the S., and by the province of Arauco on the W. It has an area of 2857 square miles, and had a population in 1895 of 98,032. It is divided into four departments—Angol, Traiguén, Mariluan, and Collipulli. Its capital is Angol (7056).

Mallorca. See BALEARIC ISLANDS.

Mallow, a town in the county of Cork, Ireland, on the river Blackwater, 150 miles south-west of Dublin by rail. It ceased to be a parliamentary borough in 1885. It is governed by town commissioners, but under the Local Government (Ireland) Act, 1898, can apply to be constituted an urban sanitary district. Population (1881), 4437; (1901), 4549.

Malmesbury, James Howard Harris, 3rd EARL of (1807-1889), English statesman, son of the 2nd Earl, was born 25th March 1807, and educated at Eton and Oriel College, Oxford. He led a life of travel for several years, making acquaintance with famous people; and in 1841 he had only just been elected to the House of Commons as a Conservative, when his father died and he succeeded to the peerage. His political career, though not one which made any permanent impression on history, attracted a good deal of contemporary attention, partly from his being Foreign Secretary in 1852 and again in 1858-59 (he was also Lord Privy Seal in 1866-68 and in 1874-76), and partly from his influential position as an active Tory of the old school in the House of Lords at a time when Lord Derby and Mr Disraeli were, in their different ways, moulding the Conservatism of the period. Moreover his long life—he survived till 18th May 1889,—and the publication of his *Memoirs of an Ex-Minister* in 1884, contributed to the reputation he enjoyed. These *Memoirs*, charmingly written, full of anecdote, and containing much interesting material for the history of the time, remain his chief title to remembrance. Lord Malmesbury also edited his grandfather's *Diaries and Correspondence* (1844), and in 1870 published *The First Lord Malmesbury and His Friends: Letters from 1745 to 1830*.

Malmö, a seaport town and important industrial centre of Sweden, on a small bay of the Sound, 384 miles by rail south-south-west of Stockholm. It is the terminus

of more than half a dozen railways, and since October 1895 has been connected with Copenhagen (17¼ miles west by north) by steam-ferry, the Sound being kept free from ice in winter by an ice-breaker. Moreover, since the summer of 1899 it has been the first important station in Sweden on the Sassnitz (island of Rügen)-Trelleborg express route (opened 30th April 1897) between Stockholm and Berlin. In 1895 the total imports (in great part coal) amounted to £1,917,000, and the exports (9 per cent. of the exports of the kingdom) to £1,572,250. The latter consisted principally of bacon and beef, butter, chalk, flour, live-stock, and matches. The shipping, which is mostly under the Swedish and Danish flags, averaged 3943 vessels of 817,500 tons cleared annually in the period 1886-96; but in 1897 it jumped up to 5093 vessels of 1,421,590 tons, and in 1900 reached 5582 vessels of 1,712,191 tons. The harbour consists of two inner basins, admitting vessels of 21 feet draught, and an outer harbour of 22 feet depth; and in 1896 a further scheme of improvement was agreed upon. There are also a dry dock, 236 feet long, and a patent slip, 400 feet long. The port owns a merchant fleet of over 50 vessels of 20,000 tons aggregate. Here Charles XV. died in 1872. St Peter's Church (1319-46) was restored in 1847-53, and again in 1889-90. There are, further, the 15th-century house of the burgo-master Jörgen Kock, a small museum, a prison (single-cell system), a technical school, new barracks (1897), and a colossal statue of Charles X. (1896). Population (1880), 38,054; (1890), 48,504; (1900), 60,857.

Malone, a village of New York, U.S.A., capital of Franklin county, in the northern part of the state, at an altitude of 756 feet. It is at the intersection of three railways, the New York Central and Hudson River, the Ogdensburg and Lake Champlain, and the St Lawrence and Adirondack. The adjacent region contains iron ore and lumber. Population (1890), 4986; (1900), 5935, of whom 910 were foreign-born.

Malstatt-Burbach, a town of Prussia, in the Rhine province, on the right bank of the Saar, nearly opposite to Saarbrücken. It has large ironworks, brickworks, breweries, and manufactures of cement, machinery, and railway carriages; also iron mining. Population (1885), 14,950; (1895), 23,677; (1900), 31,200.

Malta, an important naval and military station belonging to Great Britain, situated in the Mediterranean Sea, about 60 miles south of Sicily. The area, including the islands of Gozo and Comino, is 117,117 square miles. Malta is a Crown colony, administered by a governor, who is generally a soldier, an executive council, and a legislative council, termed "the Council of Government." The executive council consists of the governor, the senior military officer, of six other official members, and such other persons as the Crown may select. So far as possible, however, the old practice is maintained of giving seats on the council to elected members of the council of government. This body consists of the governor, the vice-president, six official members, and thirteen elected members. Of these ten are elected by the general electors, who require a small property qualification, and three by the "special electors." These "special electors" are the nobility and landed proprietors, the university graduates, and the members of the exchange. The fourth body of special electors, the ecclesiastical, is no longer represented, and has therefore ceased to be. The votes of eight elected members are necessary for the rejection of any vote in connexion with finance, and the rule forbidding officials to vote on such questions has been abrogated. In spite, however,

of these provisions, the practice of the elected members to refuse supplies, and generally to obstruct the Government, led to the free use of what was termed "the safety valve" of the 1887 Constitution, viz., the power of the Imperial authorities to legislate over the heads of the elected members by means of Orders in Council. When the elected members have refused to vote supplies, the rule has been, where purely local interests were concerned, to allow their constituents to suffer for such refusal. But where imperial questions, or local questions of such importance as to become imperial, were concerned, to impose the taxation required by Orders in Council. By this means alone was it found possible, up to 1902, to continue some form of popular government, in an island which, from the point of view of British interests, is solely a fortress, essential to the British position in the Mediterranean, without neglecting the warning contained in the duke of Wellington's well-known saying that to give a constitution to Malta was like giving a constitution to a man-of-war. At the same time it should be noted that the electorate consists of only one-eighteenth of the total population, and that of this restricted number only a small proportion takes the trouble to vote.

The local laws are based on the Roman law and Continental codes. Considerable difficulty has arisen from the uniform use of the Italian language in the law courts. It had been substituted for Latin as the official language in 1815, with the general consent, but circumstances had greatly altered. At the last census, the number of Maltese natives speaking English was almost equal to the number of those speaking Italian, while the increase in the British garrison and of visitors rendered more apparent the inconvenience of the sole use of Italian in the courts. Matters were brought to a head in February 1898 by the case of a British officer, who was at first sentenced to three days' imprisonment for contempt of court, because he had refused to sign the translation in Italian of his evidence given in English, not being satisfied that it was correct. To meet this state of things, an Order in Council (1899) was passed, under which in future, in criminal cases, when the accused was British the trial should be conducted in English. In civil cases, when either party was British, an option was given to such party, or to any person appearing in the case in any capacity, to use English. A further Order in Council (1899) was issued, declaring the intention of the Government to make English in fifteen years (*i.e.*, in 1914) the official language of the courts. This period of time was subsequently extended to twenty years. In deference, however, to the feeling aroused in Italy, this proclamation was withdrawn in 1902.

The question of the language of the law courts was closely connected with the question of education. Educational experts generally recognized that it was impossible to teach a child more than one foreign language; and Italian being a foreign language in Malta as well as English, it followed that, if Italian were to be generally taught, it must be at the expense of English. But the practical convenience of a knowledge of English to the Maltese was obvious. In this state of things an Order in Council was passed in 1899 giving parents and guardians the power to choose which language shall be taught their children in addition to Maltese. At first no less than 98 per cent. chose English, and though, under the pressure of agitation, the proportion sank to 75 per cent., it again increased. Although undoubtedly the provisions of this law aroused the fierce opposition of those who wished to maintain the Italian characteristics of Maltese civilization and culture, there can be no question but that they represented the fixed determination of the British Government. In fact, this freedom of choice was to be extended

to the parents of students in the Lyceum and University, except in the case of the faculty of theology, where the supremacy of Italian is preserved.

In deference to the religious feelings of the population, the institution of civil marriages has not been established. Difficulties have sometimes arisen from the mixed marriages of Roman Catholics and Protestants, and, in certain cases, from the inability to obtain legitimate marriage.

The following are the figures of the revenue and expenditure:—

	Revenue.	Expenditure.
1881 . . .	£185,957	£188,039
1891 . . .	275,125	281,870
1900 . . .	356,758	365,943

There is no public debt. There is no direct taxation, and the main sources of revenue are the Customs duties. Taxation is about £1 7s. 6d. per head, as against about £4 13s. in the United Kingdom in 1901.

The trade tends to decrease, owing to the competition of other Mediterranean ports. The number of steamers entering the port and the amount of their tonnage was in—

	Steamers.	Tonnage.
1881 . . .	3885	3,673,753
1891 . . .	3286	3,988,397
1900 . . .	2549	3,473,576

The imports in 1900 were £7,434,289, and the exports £6,471,567. The civil population was (1881), 149,782; (1891), 165,037; (1900), 183,679. The population of the capital, Valetta, is almost stationary, nearly 24,000, but the neighbouring suburbs have increased greatly. In 1891 Floriana had a population of 6575. Of the several cities and suburbs forming, on the borders of the two harbours, an almost uninterrupted line of inhabited localities, the most populous are "The Three Cities," namely, Vittoriosa (6902), Conspicua (12,065), and Senglea (7770). In 1891, 73,876 persons resided in the urban districts and 72,608 in the rural, which include the old city of Notabile. The average density of the population was 1570 to a square mile in 1901, as compared with 1487 in 1891 and 1332 in 1881.

Malta is an example of *la petite culture*. There were, at the time of the census of 1891, about 10,000 holdings, the average extent of which was 4·4 acres. About 30 per cent. of the whole cultivated area is under corn crops. Vegetables are grown on irrigated land throughout the year. The rent of irrigated land is from £3 per acre. Potatoes and onions are largely grown for exportation. The area under potatoes is about 5000 acres. Oranges are also grown for export. The average rainfall for the 15 years ending 1898 was 19·7 inches. The rainfall for 1900 was 16·3. The climate, although very hot in summer, appears on the whole healthy. The death-rate, which is about 27 per thousand, is increased by the neglect of proper sanitary measures.

Besides a university (77 students in 1900) and a lyceum, there are two secondary schools, one in Malta for girls and one in Gozo for boys; a technical and manual school; 38 elementary day schools for boys, 40 for girls, 20 for infants, 17 miscellaneous, and 34 night elementary schools; the elementary schools being attended by about 11,500 children. In addition there are about 130 private schools and colleges with more than 4200 scholars. Maltese only is taught in the inferior standards. In the next two standards either English or Italian is taught. The general prosperity of the islanders is indicated by the fact that at the end of 1900 there were 6960 depositors in the Maltese savings bank, with £535,571 standing to their credit, or an average of £76 19s. for each depositor. The main importance of Malta to Great Britain lies in its harbour and fortifications, which have been of late years greatly strengthened and adapted to new conditions. Besides a permanent garrison of six companies of Royal Artillery and six battalions of infantry, there are the local corps, supported in part by the imperial Government. A railway 8 miles long was opened in 1892, and has proved financially very successful.

The tradition may be accepted which regards the cathedral as occupying the site of Publius's palace. A public church appears to have been erected, after the general peace in the 4th century, on the spot where private worship had been carried on. This church survived the period of Mahommedan dominion, and was extensively repaired by Roger the Norman. The exploration and survey

of St Paul's catacombs in 1894 has thrown light on the question of early Christian burial in Malta. It is true that direct evidence from documents or epitaphs is lacking, but the representation of a scene of martyrdom is still clearly discernible in the basement of an arched tomb, and the palm-leaf, the ordinary emblem of martyrdom, is engraved on several tombs in the same chapel. Moreover, the analogy of the Roman catacombs is altogether convincing. Malta, as an allied city, not far removed from the seat of empire, must have felt the effect of the imperial decree of a. n. 64, "*non licet esse Christianos*," while "as a matter of evidence, from the similar mode of construction and economy of place, internal arrangement of details, and distribution of graves analogous to the Roman catacombs, from the same devices contrived for concealment, it is clearly apparent that our Christian forefathers had then to follow the same reconditæ cemeterial system, sunk under ground, as in Rome." The same authority adds, "The topographical situation of the ancient burial grounds, *extra urbem*, along the high roads, was strictly Roman, and the individual areas, both of our ancient pagan tombs and of our Christian cemeteries, defined by determinate boundaries conformably to the provisions of the then common law, were private properties of the natives."

The manner in which successive civilizations have occupied the same site at Notabile accounts for Greek and Roman remains being now found only in excavations. As late as 1647 relics of old buildings could still be seen in the streets, but the work of destruction has gone on. The remains of the temple of Apollo were discovered in 1747.

See *Ancient Pagan Tombs and Christian Cemeteries in the Island of Malta, Explored and Surveyed from 1831 to 1897*, by Dr A. A. CARRUANA. Malta, 1898.—For the language question, see Mr Chamberlain's speech, in House of Commons, 28th January 1902.

(H. E. EG.)

Malton, a market town in the Thirsk and Malton parliamentary division (since 1885) of Yorkshire, England, on the river Derwent, 22 miles north-east of York. In 1894 Old and New Malton were formed into one civil parish (an urban district). Population (1901), 4758.

Malvern, a health resort of England, 10 miles south-west from Worcester, in the Bewdley parliamentary division of Worcestershire. It consists of a string of little towns and villages, situated partly at the eastern foot of the Malvern Hills (1000–1440 feet), partly on their slopes, overlooking the valley of the Severn and the Vale of Evesham. At the foot of the hill are Great Malvern, Malvern Link, Malvern Wells, and Little Malvern, and higher up North Malvern and West Malvern. Owing to their pure and invigorating air, they enjoy great repute as places of residence and as health-resorts, latterly for the "open-air cure" for consumptive patients. The water, so noted for its purity, is now collected and stored for public use in waterworks. In addition there are mineral springs (two at Great Malvern, one above Malvern Wells, and one near West Malvern). Malvern College and other schools make the place of some importance as an educational centre. Population (1801), 819; (1901), 16,448.

Mamiani della Rovere, Terenzio, COUNT (1799–1885), Italian writer and statesman, was born at Pesaro in 1799. Taking part at Bologna in the outbreaks arising out of the accession of Pope Gregory XVI, he was exiled and went to France; but he returned after the amnesty of 1846, and in 1848 was made president of the council by Pius IX. This post, however, he only held for a few months, his political views being the reverse of papal. He retired to Genoa and there worked for Italian unity, and in 1860 became minister of education under Cavour. In 1861 he was made ambassador to Greece, and in 1865 to Switzerland. Meanwhile, he had founded at Genoa in 1849 the Academy of Philosophy, and in 1855 had become professor of the history of philosophy at Turin; and he published several volumes, not only on philosophical and social subjects, but of poetry, among them *Rinnovamento della filosofia antica italiana* (1836), *Teoria della Religione e dello stato* (1869), *Kant e l'Ontologia* (1879), *Religione dell'avenir* (1880), *Poems* (1843, 1857). He died at Rome, 21st May 1885.

MAMMALIA.

IN few branches of zoology have greater advances been made than in the Mammalia since the date of the appearance of the article in the earlier volumes (ninth edition) of the *Encyclopædia Britannica*. These advances, noticeable alike in the morphological, palæontological, and taxonomic aspects of the subject, are, in fact, so great as to have altered our whole conception of the relations of the group. Moreover, what may be regarded as practically a revolution in nomenclature has taken place, including the introduction of the principle of trinomialism.

In regard to the dental system (vol. xv. p. 352), it has been found that when only a single series of teeth is developed, they may belong to the milk or deciduous, and not to the permanent series; this is the case with the Cetacea and the Marsupialia (with the exception of the single replacing tooth in each jaw). Again, the statement (vol. xv. p. 354) that the cheek-teeth of Marsupials do not correspond serially with those of Placentals has not been found to hold good, and it now appears that in both groups the typical number of premolars (whether permanent or deciduous¹) is four, behind which there are three (occasionally more) molars. The section of the earlier article devoted to the placenta (vol. xv. pp. 368, 369) requires considerable modification, owing to the discovery by Caldwell in 1884 that the Monotremata are oviparous, and to Hill's announcement in 1897 of the existence of a true placenta in the Marsupial genus *Perameles*. These and other discoveries have had an important bearing on the general scheme of classification of the Mammalia, and it has been suggested that, instead of dividing the class into the equivalent subclasses Prototheria, Metatheria, and Eutheria, the division should be into two subclasses only, viz., *Prototheria* and *Eutheria*, the latter of which is divisible into the sections Marsupialia and Placentalia. Palæontological discoveries in the early Secondary rocks of South Africa and North America have had an important bearing on the question of the origin of the Mammalia, and it is now generally conceded that the class is derived from the Labyrinthodontia, or Stegocephalia, of the Permian and Carboniferous, which were Amphibian-like creatures with completely roofed skulls. Between the Stegocephalia and the Mammalia may probably be intercalated the group of Triassic and Permian Reptiles known as the Anomodontia, certain members of which present remarkable mammalian resemblances in their skeletons and teeth, while others come very close to the Stegocephalia. It is true that no small forms (ancestral mammals must necessarily have been diminutive) have hitherto been discovered which can be regarded as ancestral types of the Mammalia (Hypotheria or Promammalia), but the probability is that such were included among the Anomodontia. The question whether the Prototheria and Eutheria had a single or dual (diphyletic) origin from the Anomodontia (or Hypotheria) must for the present remain in abeyance, although there are good grounds for thinking that the latter alternative may prove the true solution of the problem. Much depends upon future investigations in regard to the structure of the Eutherian ovum; and if this proves to be amphibian in character the argument for a dual origin will be overwhelming, since the Monotreme (Prototherian) egg is certainly of a reptilian type.²

¹ It has been found convenient to speak of the milk-molars as "milk-premolars."

² See a paper on the Origin of Mammals, by Prof. H. F. Osborn, in the *Proceedings* of the International Congress of Zoology, 1898.

Prototheria.—Turning to the extent and characters of the subclass Prototheria (vol. xv. pp. 371, 377), this is now generally taken to include not only the existing order Monotremata (as represented by the *Ornithorhynchidae* and *Echidnidae*), but also an extinct group—the Multituberculata—of which the genus *Plagiaulax* (vol. xv. p. 376, Figs. 20, 21) and probably *Stereognathus* (*ibid.* Fig. 17) are representatives. These Multituberculata, which were abundant in the Jurassic and Cretaceous rocks and survived till the Eocene Tertiary, appear to have been intimately connected with certain Anomodont Reptiles, such as the South African *Tritylodon* (long regarded as a mammal); and this relationship, in spite of a theory as to the splitting-up of the multituberculate molar, speaks strongly in favour of the dual origin of the Prototheria and Eutheria, since it seems certain that the primitive carnivorous and insectivorous forms of the latter group cannot be derived from animals with a dentition of the type of *Tritylodon* and the Multituberculata. The Triassic *Microlestes* (vol. xv. p. 375) is probably a relative of *Tritylodon*.

As already mentioned, it has been ascertained that the females of the Monotremata lay eggs, which develop in the same manner as those of Birds and Reptiles, a portion only of the yoke segmenting to form the embryo, while the remainder serves for the nutriment of the latter. In the case of *Ornithorhynchus* it has been said that two eggs are laid in the chamber at the end of the burrow,³ but those of the *Echidnidae* are carried about in the pouch on the abdomen of the female, which becomes enlarged during the time of incubation. The temperature of the Monotremata has also been found to be lower than that of other mammals. The existence of true teeth in *Ornithorhynchus* is another discovery made since 1883. Three pairs of these teeth are developed in the upper, and three in the lower jaw; after being for some time in use, they gradually become worn away, and are finally shed. Under and around the teeth are developed the horny plates, or cornules, which gradually grow round them and assume their function, the hollows on the surface of the cornules indicating the positions of the teeth. In form these teeth make a distant approximation to the molars of some of the extinct Multituberculata.

Marsupialia.—The discovery of a rudimentary placenta in *Perameles*, together with that of vestiges of a second series of teeth, suggests that the Marsupialia are a degenerate rather than a primitive type, although probably one of great antiquity. Instead of the one deciduous tooth developed in certain living genera (vol. xv. p. 378, Fig. 23) being the only one corresponding to the milk-series of the Placentalia, it is its successor which alone represents the permanent premolar of the latter; this successional tooth being the third permanent premolar of the typical series of four premolars, and the one immediately behind it the fourth milk-premolar. Hence only the three last teeth, in cases when there are seven in the cheek-series, are the molars. Accordingly, in all cases where the dental formula of the Marsupialia is given in the original article as $p \frac{3}{3}$, $m \frac{4}{4}$, it should be amended to $mp + pp \frac{4}{4}$, $m \frac{3}{3}$. (See *Proc. Zool. Soc. Lond.* 1899, p. 922.)

Mr B. A. Bensley (*American Naturalist*, 1901), starting with the well-known fact that the group simulates most of the placental orders, states that its evolution, or "radiation," has taken place within its present habitat. Reasons

³ There does not appear to be authentic evidence that the eggs in this genus are actually laid.

are given for regarding the Banded Anteater (*Myrmecobius*) as a degraded type; and if this view be accepted, all the other types can be derived, both as regards their dentition and their feet, from the American Opossums, the ancestors of which are regarded as the proximate progenitors of the group. All the Australian Marsupials thus appear to have had an arboreal ancestry; and when, in spite of the specialization of certain forms, the primitive character of the whole group is borne in mind, it seems evident that the date of the "radiation" is comparatively recent. Hence the author is inclined to side with those who consider that Marsupials first entered Australia during the Tertiary period, although he thinks their arrival was later than has previously been considered possible. As to whether their immigration was from the north or from the south he is undecided, although he states that "there is at least some justification for the view that it was from the northward," *i.e.*, by way of Asia.

Of all the palæontological discoveries, few are more interesting than the occurrence of extinct Marsupials in the Miocene of South America allied to the Australian *Dasyuridae*. Two of the best-known genera are *Prothylacinus* and *Amphiproviverra*, the former being an animal agreeing closely in size and dentition with the Thylacine, but having two pairs of milk-premolars in each jaw replaced by permanent premolars. In this respect the extinct form departs one step less from the placental type than does its existing analogue, and these and other fossil forms, such as *Borhyaena*, seem to indicate an intimate relationship between the Polyprotodont Marsupials and the Creodont Carnivora, as represented by *Hyænodon* (vol. xv. p. 442, Fig. 122); the dental formula of the two, according to the new method of notation, being, so far as the cheek-teeth are concerned, identical, save for the fact that all the premolars of the Creodontia belong to the second or permanent series. On this view the Creodontia have retained a tooth-change which is lost in the modern Marsupials; and both may be descended from Mesozoic forms like *Triconodon* and *Amphitherium*, in the former of which all four premolars were replaced.

FIG. 1.—Marsupial Mole (*Notoryctes typhlops*).

An additional family (*Notoryctidae*) of Polyprotodont Marsupials is represented by the Marsupial Mole (*Notoryctes typhlops*), from the deserts of central South Australia (Fig. 1). This is a small burrowing animal, of a pale golden-yellow colour, with long silky hair, a horny shield on the nose, and a stumpy leathery tail. The feet are five-toed, and the third and fourth toes of the front pair armed with enormous claws adapted for digging. Neither ear-cochleas nor eyes are visible externally. There are but three pairs of incisor teeth in each jaw, and the upper molars are tricuspid. This animal spends most of its time burrowing in the sand in search of insects and their larvæ, but occasionally makes its appearance on the surface.

Of even greater interest than *Notoryctes* is the discovery of a family (*Epanorthidae*) of Diprotodont Marsupials in South America, the majority of the members of which are extinct, their remains being found in the Miocene of Patagonia, although one existing genus (*Cænolestes*) survives in Ecuador and Colombia. One of the two living species was, indeed, described so long ago as the year 1863, under the preoccupied name of *Hyænodon*, but attracted little or no attention, as its affinities were not fully recognized. Externally *Cænolestes* has a shrew-like appearance. The elongated skull (Fig. 2) has four pairs of upper incisors and long upper canines, while in the lower jaw there is a single pair of procumbent incisors, followed by several small teeth representing the canine and earlier premolars. The three pairs of molars in each jaw are, like the last premolar, quadritubercular oblong teeth. The five-toed feet are of normal structure, and the rat-like tail is prehensile towards the tip. The female has a small pouch. The extinct members of the family are represented by the genera *Epanorthus*, *Acelestis*,

Garzonia, &c. In a second family—*Abderitidae*—also from the Patagonian Miocene, the penultimate premolar is developed into an enormous tooth, with a tall, secant, and grooved crown, somewhat after the fashion of the enlarged premolar of *Plagiailax*. From the structure of the skull it is thought probable that *Abderites* had an elongated snout, like that of many Insectivora.

As regards other discoveries in connexion with the Marsupialia, it must suffice to say that complete skeletons of the extinct

FIG. 2.—Skull of *Cænolestes obscurus*.

Australian *Diprotodon* (vol. xv. p. 383) have been disinterred and described by Dr Stirling, from which it has been ascertained that in the structure of the feet this genus shows resemblances both to the *Phalangeridae* and the *Phascologyidae*, but comes nearer to the former. *Phascolonus* (*Sceparnodon*), from the same deposits, was a giant Wombat. It may be added that a large mammal (*Pyrotherium*), with cheek-teeth like *Diprotodon*, from the Miocene of Patagonia, may possibly prove to be a Diprotodont Marsupial, although this is not very likely.

Edentata.—The result of recent discoveries has been to discount the supposed isolation of the Edentata (vol. xv. p. 383), and to bring them more into line with other Placentals. The connecting forms are a group of Eocene mammals termed Ganodontia, as represented by the genera *Psittacotherium*, *Calamodon*, *Hemiganus*, *Stylinodon*, &c., all of which are typically North American. In this group front teeth were present, and the cheek-teeth of the earlier types were rooted and invested to a considerable extent with enamel, their unworn crowns being tricuspid. An approximation to the true Edentata is revealed in the later types by the gradual abortion of the incisors, and of the roots of the cheek-teeth; the latter grow from persistent pulps, and have their enamel restricted to vertical bands. Among the Edentata of the family *Mega[lo]theriidae*, especial interest attaches to the discovery in a cave in South Patagonia of remains of the genus *Glossotherium*, or *Grypothierium* (vol. xv. p. 385), a near relative of *Mylodon*, which include a considerable portion of the skin with the hair attached. Ossicles somewhat resembling large coffee-berries had been previously found in association with the bones of *Mylodon*, and in *Glossotherium* nearly similar ossicles occur embedded on the inner side of the thick hide. The coarse and shaggy hair is somewhat like that of the Sloths. The remains, which include not only the skeleton and skin, but likewise the droppings, were found buried in grass which appears to have been chopped up by man, and it thus seems not only evident that these Ground-Sloths dwelt in the cave, but that there is a considerable probability of their having been kept there in a semi-domesticated state by the early human inhabitants of Patagonia. The extremely fresh condition of the remains has given rise to the idea that *Glossotherium* may still be living in the wilds of Patagonia, but this is improbable.

Although a few of the Pleistocene Ground-Sloths, such as *Nothropus* and *Nothrotherium* (= *Calodon*, vol. xv. p. 385) were of comparatively small size, in the Miocene of Patagonia few of the representatives of the family much exceeded the modern Sloth in size. The best-known generic types are *Eucholaxops* (*Hapalops*) and *Pseudahalops*, of which considerable portions of the skeleton

have been disinterred. In these diminutive Ground-Sloths the crowns of the cheek-teeth approached the prismatic form characteristic of *Mega[lo]therium*, as distinct from the subcylindrical type occurring in *Mylodon*, *Glossotherium*, &c. It should be added that the North American Tertiary forms described as Edentates under the name of *Moropus* and *Morotherium* (vol. xv. p. 385) are now ascertained to be aberrant Ungulates allied to *Chalicotherium*.

In addition to the discovery of certain new types of Pleistocene Armadillos (*Dasypodidae*), one of which is far larger than any species previously known, important advances have of late years been made in our knowledge of the allied extinct South American family *Glyptodontidae* (vol. xv. p. 388, where it is termed *Hoplophoridae*), now ascertained to date at least from the Miocene. Here it has to be mentioned that the restoration of *Glyptodon* copied from Owen (vol. xv. p. 387, Fig. 39) is quite incorrect, that which is made to do duty for the entire tail being the terminal portion of the tail-sheath of a totally different genus. In *Glyptodon* (with which *Schistopleurum* is identical) the tail-sheath consists of a series of coronet-like rings, gradually diminishing in diameter from base to tip. *Dædicurus*, in which the tail-sheath is in the form of a huge solid club, is the largest member of the family; in *Panochthus* and *Lomaphorus* (*Hoplophorus*) the tail-sheath consists basally of a small number of smooth rings, and terminally of a tube. In some specimens of these genera the horny shields covering the bony scutes of the carapace have been preserved, and since the foramina, which often pierce the latter, stop short of the former, it is evident that these were for the passage of blood-vessels and not receptacles for bristles. All the above are of Pleistocene and perhaps Pliocene age, but in the Miocene of Patagonia there occur the two curious genera *Propalæohoplophorus* and *Peltephilus*, the former of which is a primitive and generalized type of Glyptodont, while the latter seems to come nearer to the Armadillos. Both are represented by species of comparatively small size. In *Propalæohoplophorus* the scutes of the carapace, which are less deeply sculptured than in the larger Glyptodonts, are arranged in distinct transverse rows, in three of which they partially overlap near the border of the carapace after the fashion of the Armadillos. The skull and limb-bones exhibit several features met with in the latter, and the vertebrae of the back are not welded into a continuous tube. There are eight pairs of teeth, the first four of which are simpler than the rest, and may perhaps therefore be regarded as premolars. More remarkable is *Peltephilus*, on account of the fact that the teeth, which are simple, with a chevron-shaped section, form a continuous series from the front of the jaw backwards, the number of pairs being seven. Accordingly, a modification of the character, even of the true Edentata, as given in the earlier article, is rendered necessary. The head bears a pair of horn-like scutes, and the scutes of the carapace and tail, which are loosely opposed or slightly overlapping, form a number of transverse rows.

The so-called Old-World Edentata—the families *Manidae* and *Orycteropodidae* (vol. xv. p. 388)—have been assigned to an order apart, under the name of Effodientia. *Orycteropus* has been ascertained to possess milk-teeth, and fossil representatives of the genus have been obtained from the Pliocene of Persia, Greece, and Samos. The presumed extinct Edentata of the Old World mentioned on p. 388 of the earlier article have proved to be Ungulata, and are referred to below.

Sirenia and Cetacea.—As regards the former order, it will suffice to say that in the Manatee the number of teeth has been proved to be at least twenty pairs in each jaw, and may possibly be as many as thirty; and that *Trichechus* is now taken as the name of the genus, the Walrus being termed *Odobenus*. In the palæontological history of the Cetacea some important items have been furnished by the Tertiary strata of Patagonia. In the first place, a small Sperm Whale, tentatively assigned to the extinct European genus *Physodon*, has a full series of enamelled teeth in the upper jaw, and therefore, unless it be made the type of a separate family, entails a modification in the definition of the *Physeteridae* (vol. xv. p. 395). Even more interesting is *Arygrocetus*, also from the Miocene of Chubut, on account of the fact that the occipital condyles, instead of being adpressed to the skull, are as prominent as in any ordinary mammal, and that the nasals are squared bones covering the hinder part of the nose-chamber. The latter feature was pre-

viously unknown among the Toothed Whales, and its occurrence in the Patagonian genus removes one of the objections which have been urged against the possibility of the Whalebone Whales tracing their descent to the aforesaid group. Yet another Chubut Cetacean—*Prosqualodon*—indicates a distinct type of *Squalodontidae*, characterized by the shortness of the skull, the nasal bones in this genus also roofing over the chamber of the nose to a small extent. Recent researches tend to show that the extinct *Zeuglodon* was furnished with bony armour.

Rodentia.—Since no very remarkable discoveries of new forms—either living or extinct—have been made in the orders Insectivora and Chiroptera, these may be passed

FIG. 3.—*Idiurus Zenkeri*.

over with the observation that considerable modifications have been made in the taxonomy and nomenclature of the latter group. Among the Rodentia, on the other hand, not only are the taxonomic and nomenclatural changes greater, but many interesting new forms have been discovered. The Tillodontia (vol. xv. p. 432), as typified by *Tillotherium*, but including *Esthonyx* and other forms, all of which occur in the Eocene of North America, are now generally regarded as a primitive section of the order, to which in taxonomic series the Duplicidentata will come next. In these Tillodonts the skull, although to a great extent Rodent-like, exhibits archaic features in the form and size of the brain-cavity, as it does in the retention of small

canines and the anterior premolars. On the other hand, the incisors—especially one pair—exhibit an approximation to the scalpriform character of those of modern Rodents, this being less apparent in the earlier *Esthonyx* than in the later *Tillotherium*.

For the modifications in the taxonomy of the true Rodents, the reader may consult a paper by O. Thomas in the *Proc. Zool. Soc. London* for 1896, and a monograph of the order by T. Tullberg, published at Upsala in 1899; the views of these writers are by no means altogether in accord. All are now agreed that the *Anomaluridae* (vol. xv. p. 417) are markedly different from the Squirrels. Two new West African representatives of the group—*Idiurus* (Fig. 3) and *Zenkerella* (Fig. 4)—have been discovered, the second of these

FIG. 4.—*Zenkerella insignis*.

being devoid of a flying membrane. From the Miocene of North America has been described the extinct family *Mylagaulidae*, allied to the *Castoridae*. In the *Muridae* a host of new existing forms have been found, among the more interesting being *Xeromys*, *Leptomys*, and *Chrotomys*, allied to the previously isolated Australian genus *Hydromys*, which is restricted to the Philippines and Australia. Other peculiar Philippine Murines are *Batomys*, *Carpomys*, *Rhynchomys*, and *Crateromys*, all being confined to the mountains of Luzon; the third is remarkable for its Shrew-like muzzle, and the fourth for its huge size and long hair. The *Bathyergidae* (vol. xv. p. 419) have been separated as a family from the *Spalacidae*, and the *Heteromyidae* from the *Geomyidae*. From a distributional point of view the discovery of a Jumping Mouse (*Zapus*) in north-eastern Asia is important. The Cape Jumping Hare (*Pedetes*, vol. xv. p. 420) is now removed to the *Hystricomorpha*, where it forms a family by itself, in the neighbourhood of which some consider the *Anomaluridae* should find a place. From the Old-World *Hystricidae* the American Porcupines have been separated as a distinct family, under the name of *Erethizontidae*. The *Hystricomorpha* have always been strongly represented in South America, and a number of extinct types more or less intimately related to the existing representatives of the group have been recorded from the Miocene of Patagonia. None of these demand, however, special mention, with the exception of *Megamys*, which was a huge Rodent allied to the Capybara, estimated to have rivalled an ox in bulk.

Ungulata.—Very great has been the advance in our knowledge of the past history of this order since 1883, more especially as regards the South American Miocene

forms, and it is now no longer practicable to subdivide the order into the two groups of *Ungulata Vera* and *Subungulata* (vol. xv. p. 422). The most primitive representatives of the group are the Eocene forms constituting the suborder *Condylarthra*, of which the North American *Phenacodus* and *Hyracops* are the best known. In these small and generalized *Ungulata*, which are but little differentiated from the ancestral *Carnivora*, the brain is small and smooth, the cheek-teeth are short-crowned and tuberculated, with the premolars less complicated than the molars, the number of the teeth being usually the typical forty-four. The articular heads of the bodies of the vertebræ are flat, the lower end of the humerus is perforated on the inner side, and the feet, which are more or less plantigrade, are five-toed, with the median digit the largest of the series. In the carpus the bones of the upper and lower row are arranged in vertical lines, without being alternated (vol. xv. p. 422, Fig. 100). Teeth resembling those of *Phenacodus* occur in the Swiss Eocene bone-beds.

Hyracoidea.—All the existing representatives of this suborder are now termed *Procavia*, instead of being classed in two genera as *Hyrax* and *Dendrohyrax*. More important is the occurrence of an extinct genus—*Pliohyrax*—in the Pliocene of Greece and Samos, its lower jaw having long ago been described under the preoccupied name *Leptodon*. A skull from the Miocene of Patagonia has been named *Archæohyrax*, and, if really referable to the present group, is of much interest, especially if, as seems probable, some of the under-mentioned *Toxodonts* are related to the *Hyracoidea*.

Toxodontia.—As the description of the suborder *Amblypoda* requires but little amendment, it must suffice to say that the proper title of its typical family is *Umtatheriidae*. At the conclusion of the notice of the *Amblypoda* in the earlier article (vol. xv. pp. 426, 427) mention is, however, made of several extinct South American *Ungulates* whose position was left uncertain. Later discoveries have done much towards elucidating the true relationships of these and other forms, which are now assigned to several distinct suborders of *Ungulata*, showing more or less marked signs of affinity with the *Perissodactyla*. It may eventually become a question whether it will not be advisable to extend the limits of the latter suborder to include all these extinct groups, together with the existing *Hyraces*.

Under the suborder *Toxodontia* may be included not only the typical *Toxodon*, but the more aberrant *Typotherium* (or *Mesotherium*) (vol. xv. p. 427, Fig. 106) of the Pleistocene of Buenos Aires, and the smaller *Pachyrucos* and *Hegetotherium* of the Patagonian Miocene. All the members of the suborder have tall-crowned and curved cheek-teeth, some or all of which have persistent pulps, while at least one pair of incisors are rootless. The bodies of the cervical vertebræ have flat articular surfaces, the bones of the two rows of the carpus alternate, and in the tarsus the navicular articulates with the calcaneum, which, as in the *Artiodactyla*, is articulated to the fibula, while the astragalus, which is slightly grooved above, is formed on the *Perissodactyle* plan. The number of toes varies between three and five, of which the middle one is the largest, and the femur may or may not have a third trochanter. The *Typotheriidae* and *Pachyrucidae* are remarkable among the *Ungulates* for the retention of clavicles, and for their curious approximation in dentition and certain characters of the skeleton to the *Rodentia*. The dental formula of *Typotherium* is given in vol. xv. p. 427; that of the smaller Patagonian forms differs by the larger number (3) of premolars. The toes were unguiculate rather than unguulate. Certain allied Patagonian forms appear to show distinct affinity to the *Hyraces*.

The *Toxodontidae* differ from the preceding family by the loss of the clavicles, and the reduction of the digits to three in each foot. The typical genus *Toxodon* is represented by animals the size of a Rhinoceros, of which the entire skeleton is now known. The teeth, of which the approximate formula is given in vol. xv. p. 427, all grow from persistent pulps; those of the cheek-series are very tall, highly curved, and with a simplified crown-structure. In the Miocene *Nesodon*, on the other hand,

the cheek-teeth are shorter-crowned, and depart less widely from a generalized Perissodactyle type, the total number of teeth being forty-four, and there being scarcely any gap in the series. Very remarkable changes occur in the dentition as age advances, most of the teeth eventually developing roots. Although the complete skeleton is not yet known, it is ascertained that the femur differs from that of *Toxodon* in the retention of a third trochanter.

Astrapotheria.—Another group of Ungulates confined to the Miocene of Patagonia is typified by the genus *Astrapotherium*, represented by huge animals with cheek-teeth singularly like those of a Rhinoceros, and an enormous pair of tusk-like upper incisors, recalling the upper canines of *Machærodus* on an enlarged scale. In the lower jaw are two large tusk-like canines, between which are three pairs of curiously-formed spatulate incisors, and in both jaws there is a long diastema. The dental formula appears to be $i \frac{1}{2}, c \frac{1}{1}, p \frac{2}{2}, m \frac{3}{3}$.

Here may be provisionally placed the genus *Homalodontotherium*, of which the imperfect skull was alone known in 1883 (vol. xv. p. 427). The teeth have much lower crowns, and are of a less decidedly Rhinocerotid type than in *Astrapotherium*, and the whole dentition forms an even and unbroken series. The bodies of the cervical vertebræ are short, with flattened articular surfaces, the humerus has an enormous deltoid crest, suggestive of fossorial powers, and the femur is flattened, with a third trochanter. According to the Argentine palæontologists, the carpus is of the alternating type, and the terminal phalanges of the pentadactyle feet are bifid, and very like those of Edentata. Indeed, this type of foot shows many Edentate resemblances. The astragalus is square and flattened, articulating directly with the navicular, although not with the cuboid, and having a slightly convex facet for the tibia. From the structure of the above-mentioned type of foot, which is stated to have been found in association with the skull, it has been suggested that *Homalodontotherium* should be placed in the Perissodactyle family *Chalicotheriidae*; but, to say nothing of the different form of the cheek-teeth, all the other South American Miocene Ungulates are so distinct from those of other countries that this seems unlikely. It may be suggested that we have rather to deal with an instance of parallelism—a view supported by the parallelism to the *Equidae* presented by certain members of the next group.

Litopterna.—A fuller study of the remains of the South American Pleistocene genus *Macrauchenia* (vol. xv. p. 428) shows that it can no longer be included in the Perissodactyla, as at present understood, and that it typifies a sub-order containing a number of Miocene forms. All were digitigrade forms, recalling in general build the Llamas and Horses; they have small brains, and a facet on the calcaneum for the fibula. The cheek-dentition approximates more or less to the Perissodactyle type. Both the terminal faces of the cervical vertebræ are flat, the femur carries a third trochanter, the bones of both the carpus and tarsus are arranged in linear series, and the number of toes, although commonly three, is stated to vary between one and five, the third or middle digit being invariably the largest. Of the two families, the first is the *Protheroheriidae*, which exhibits, in respect of the reduction of the digits, a curious parallelism to the equine line among the Perissodactyla; in this feature, as well as in the reduction of the teeth, it is more specialized than the second family.

The molar teeth approximate to the *Palæotherium* type, but have a more or less strongly developed median longitudinal cleft. The three-toed type is represented by *Diadiaphorus*, in which the dental formula is $i \frac{1}{2}, c \frac{1}{1}, p \frac{2}{2}, m \frac{3}{3}$, and the feet are very like those of *Hipparion*. The cervical vertebræ are of normal form, the orbit (as in the second family) is encircled by bone, the last molar has a third lobe, the single pair of upper incisors are somewhat elongated, and have a gap between and behind them, while the outer lower incisors are larger than the inner pair, the canines being small. The skull has a short muzzle, with elongated nasals. Remains of this and the other representatives of the group are found in the Patagonian Miocene. In *Protheroherium*, which includes smaller forms having the same, or nearly the same, dental formula, the molar teeth differ from those of *Diadiaphorus* by the deeper median longitudinal cleft, which completely divides the crown into an inner and an outer moiety, the two cones of the inner half being united. According to the description given by Argentine palæon-

tologists, this genus is also three-toed, the single-toed representative of the family being separated as *Thoatherium*, but further information with regard to this point is desirable. It is, however, certain that there is a monodactylate representative of the family, in which the lateral metapodials, or splint-bones, are even more reduced than in the *Equidae*.

In the second family—*Macraucheniidae*—the dentition is complete (forty-four) and without a gap, the crowns of nearly all the teeth being of nearly uniform height, while the upper molars are distinguished from those of the *Protheroheriidae* by a peculiar arrangement of their two inner cones, and the elevation of the antero-posterior portion of the cingulum so as to form an extra pit on the crown. To describe this arrangement in detail is impossible here, but it may be stated that the two inner cones are closely approximated, and separated by a narrow V-shaped notch on the inner side of the crown. The elongated cervical vertebræ are peculiar in that the arch is perforated by the artery in the same manner as in the Llamas. In the Miocene of Patagonia the family is represented by the generalized genus *Oxyodontotherium* (in which *Theosodon* may apparently be included). It includes animals ranging up to the size of a Tapir, in which the nostrils were more or less in the normal anterior position, and the cheek-teeth were short-crowned with the inner cones of the upper molars well developed and separated by a notch, and the pits of moderate depth. The last upper premolar is simpler than the molars, and the canine, which may be double-rooted, is like the earlier premolars. The radius and ulna, like the tibia and fibula, are distinct, and the metapodials are rudimentary. On the other hand, in *Macrauchenia*, which was a much larger Llama-like animal, the skull is elongated and narrow, with rudimentary nasals, and the aperture of the nose placed nearly on the line of the eyes and directed upwards, the muzzle not improbably having terminated in a short trunk. Deep pits on the forehead probably served for the attachment of special muscles connected with the latter. Very curious is the structure of the cheek-teeth, which are high-crowned, with the two inner cones reduced to mere points, and the pits on the crown-surface large and funnel-shaped. In fact, the Perissodactyle type is almost lost by the specialization. The cervical vertebræ and limb-bones are very long, the radius and ulna being completely and the tibia and fibula partially united. The typical *M. patagonica* is a Pleistocene form as large as a Camel, ranging from Patagonia to Brazil, but remains of smaller species have been found in the Pliocene (?) of Bolivia and Argentina. It remains to add that the imperfectly known *Scalabrinia* of the Argentine Pliocene appears to occupy a position intermediate between *Oxyodontotherium* and *Macrauchenia*, having the nasal aperture situated in the middle of the length of the skull, and the crowns of the cheek-teeth nearly as tall as in the latter, but with the lower molars furnished with a projecting process in the hinder valley, similar to one occurring in those of the former.

Perissodactyla.—Since 1883 it has been discovered that the teeth described from the Upper Tertiary deposits of Europe, India, and North America as *Chalicotherium* (vol. xv. p. 429) belong to the same group of animals as the Edentate-like limb-bones to which the names *Macrotherium*, *Ancylotherium*, *Moropus*, and *Morotherium* have been assigned. In spite of the Edentate-like feet, the teeth are so like those of *Titanotherium*, while the cervical vertebræ and upper limb-bones are so essentially Perissodactyle in character, that it seems best to regard the *Chalicotheriidae* as a branch of the Perissodactyla, in which the feet have acquired (or ? retained) an unguiculate character. Some palæontologists prefer, however, to regard them as a distinct suborder, under the name of Ancylopoda. In this connexion it is important to observe that remains of *Titanotherium*

(vol. xv. p. 429) have been recorded from the Balkans, and that the North American Tertiary genera *Palæosyops*, *Limnosyops*, and *Limnotherium* indicate a family (*Limnotheriidae*) closely allied in dental character to the *Titanotheriidae*, but with a less complex fourth upper premolar, and no horn-like protuberances on the skull. Great advances have been made in our knowledge of the extinct Perissodactyla forming the ancestral stocks from which the existing representatives of the suborder have originated.

Artiodactyla.—Somewhat similar observations apply in the case of the Artiodactyla, the working out by American palæontologists of the complete descent of the Camels, from materials supplied by the Tertiary deposits of their own country, being one of the most important discoveries. Remains of true Camels (*Camelus*), it may be mentioned, have been obtained from the Pliocene of North Africa, Russia, and Rumania. *Agriochoerus*, an ally of the Orodonts, from the North American Miocene, is now known to have had claws like phalanges, the limbs having been described as *Artionyx* and *Mesonyx*. The Giraffe family, for which the name *Giraffidae* is now adopted in place of *Camelopardalidae* (vol. xv. p. 432), is now known to include the living African Okapi (*Ocapia*), together with a number of extinct types. The Okapi (see coloured Plate), discovered by Sir H. Johnston in the Semliki forest, between Lakes Albert and Albert Edward, is known by two skins, two skulls, and a slightly incomplete skeleton. The skull and dentition (only partially described at the date of writing) are distinctly Giraffe-like, the former being much more depressed than in the Giraffe. The general form of the animal is

also Giraffe-like, but the neck and limbs are proportionately much shorter, and the ears are very large and broad. The immature specimen in the British Museum stands about 5 feet at the withers. Very remarkable is the coloration. Most of the upper parts are chocolate-brown, with a purplish tinge; but the sides of the face are pale puce, the forehead and ears reddish, and the nose and muzzle blackish, while the upper portion of the fore-limbs, and the buttocks, thighs, and upper part of the hind-legs are marked with wavy horizontal black stripes on a buff ground. Except for a black ring on the fetlocks, the hind-legs below the hocks are uniformly buff, but the fore-legs below the knees have in addition a longitudinal black stripe in front. The only reason that can be suggested for this strange type of coloration is that the forest is clear of foliage up to about the height of the animal's thighs. In the British Museum specimen rudiments of a pair of horns are visible on the forehead, and other specimens show that in the adult state both sexes are horned. *Ocapia* is allied to *Palæotragus* (from which *Samotherium* is probably inseparable), of the Pliocene of Greece, Samos, and Persia, in which the males were horned and the females hornless. *Helladotherium*, from the Grecian Pliocene, is an apparently hornless type. *Sivatherium*, *Hydasphitherium*, and *Bramatherium* from the Indian, and *Libytherium* from the North African Pliocene, are now known to be gigantic giraffoids, in the males of which one pair of horns at least were branched. In *Sivatherium* a simple pair of nasal horns stand in advance of the large branched, while in *Bramatherium* an occipital pair are placed behind the branched frontal horns.

Proboscidea.—The origin and birthplace of the Proboscidea have long been a puzzle to students of evolution and distribution, the Mastodons suddenly making their

appearance in the middle part of the Miocene, without our having hitherto had the slightest clue as to their connexion with more generalized types. The puzzle has, in a great degree, been solved by Dr C. W. Andrews, who, while travelling in the Fayum district of Egypt with Mr H. J. L. Beadnell, came across two Tertiary deposits which have yielded a previously unknown vertebrate fauna, a part of which is described in the *Geological Magazine* (September 1901). From the upper beds, provisionally regarded as Lower Oligocene, were obtained remains of a small Mastodon-like animal (*Palæomastodon*), differing from *Mastodon* by the simpler last molar and

FIG. 5.—Dentition of *Mœritherium lyonsi*. One-fourth natural size. (A) Upper teeth; (B) front of snout, showing the tusk-like second incisors; (C) left ramus of mandible from outer side. (From the *Geological Magazine*).

by having five pairs of cheek-teeth simultaneously in use. The other remains are from a lower horizon, perhaps Upper Eocene, but possibly newer. Most remarkable is a primitive proboscidean (*Mœritherium*), with a nearly full series of front- and cheek-teeth, the latter being of a generalized Ungulate type. That this animal is an ancestor of the mastodons and elephants may be inferred from the enlargement of the second pair of incisors in both jaws and the small upper canines (Fig. 5). All the six pairs of cheek-teeth were in use at the same time. More problematical are the affinities of a huge Ungulate described as *Barytherium*, which in many respects resembles *Dinotherium*, but in others seems to approach the gigantic *Uintatherium* of the North American Tertiaries.

Carnivora.—The palæontological history of the Carnivora Vera (vol. xv. p. 433) shows that the triple division of the order into the sections *Æluroides*, *Cynoidea*, and *Arctoidea* is no longer tenable. The *Canidae*, which is one of the most primitive families of the group, passes imperceptibly into the *Ursidae*, while the *Mustelidae* are just as intimately connected with the *Viverridae*. The *Æluridae* (*Æluridae*, vol. xv. p. 441) are now generally included in the *Procyonidae*; and remains of a large species of the typical genus *Ælurus* have been discovered in the Pliocene of England and the Continent. Moreover, from the study of the skeleton, Professor Ray Lankester (*Trans. Linn. Soc.—Zool.* 1901) has shown that, instead of being a bear, *Æluropus* (vol. xv. p. 441, Fig. 121) is nearly allied to *Ælurus*.

Primates.—Two very remarkable extinct lemuroids of large size have been discovered in the superficial deposits of Madagascar, in one of which (*Megaladapis*) the upper

THE OKAPI (Immature).

cheek-teeth are of a tritubercular type (Fig. 6), while in the second and smaller form (*Nesopithecus*) the dentition makes a notable approximation to that of the *Cercopithecidae*. Possibly these gigantic lemuroids were living in the times of the early voyagers. Dr F. Major has also discovered a remarkable similarity in the structure of the internal ear between the existing Malagasy lemurs and *Adapis* of the European Oligocene. From the Miocene of Patagonia have been obtained remains of a genus (*Homunculus*) nearly allied to the existing *Cebidae*. Much interest has been attracted by the discovery in a bed of volcanic ash in

FIG. 6.—Skull and hinder upper cheek-teeth of *Megaladapis*.

Java of the imperfect roof of a skull, together with two molar teeth and a thigh-bone, supposed to indicate a very low type of man-like creature, for which the name *Pithecanthropus erectus* has been suggested. The forehead is extremely low, with beetling brow-ridges, and the whole calvarium presents a curiously gibbon-like aspect. Although the capacity of the brain-case is estimated to have equalled but two-thirds that of an average modern man, the creature still appears to have been a member of the family *Hominidae*—assuming that all the remains are associated. (R. L.*)
